On the other hand, a piece of metallic iron immersed in 200 c.c. of beer, produced, in two hours' time, the same yellow froth and inky flavour as in the former case, 0.15 gm. of iron having been dissolved (chiefly as ferrous oxide). On removing the metal, and leaving the beer for a few days, the dissolved iron was found to have become oxidised to the ferric condition, the flavour diminishing as in the original sample. By this and other experiments, the cause of the phenomena was traced to the iron bung-hole rings fitted to the transport casks, the iron of which is dissolved by the acids in the beer. As wort is also capable of the same solvent action, it is therefore advisable to coat all iron utensils or appliances, exposed to beer or wort, with varnish or other protective covering.—C. S.

*Beer, Influence of Dissolved Iron on the Colour of the Froth of, and on the Taste of.* Wochenschr. f. Bran. 1897, 14, 118.

IT has been recently shown by Brand that beer has a very decided solvent action on metallic iron, which imparts to it a strong inky flavour, whilst the froth becomes of a yellow colour (see preceding abstract). The iron was found to be

present partly in the ferrous and partly in the ferric condition. Beer wort is much slower in its action on iron, and this is attributed to the absence of carbonic acid. The fact that so few complaints are heard of iron contamination, in spite of the extensive employment of iron bushes, may perhaps be due to a protecting coating of oxide. This suggestion, which is brought forward by Brand, does not accord, however, with the experience of Widemaijer, who finds that the formation of rust assists the solution of iron by beer. The coating of oxide mentioned by Brand is, however, probably not ordinary rust, but rather a stable oxide artificially produced.—A. K. M.

*Beer, On the Carbohydrates in.* P. Petit. *Comptes Rend.* 1897, **124**, 510—511.

By keeping beer for three months at a low temperature, it contains about one-half of the extracts in the state of dextrin. From the behaviour of a certain quantity of dextrin isolated from 30 litres of beer, the author concludes that it differs from the dextrin of commerce. On hydrolysing the crude dextrin from beer, glucose is obtained, but at the same time other sugars are formed having a lower reducing power and a smaller or negative rotation. The presence of other sugars is also indicated after inversion, by the formation of two osazones, one separating in the heat, the other in the cold. Whilst commercial dextrin was inverted by dilute hydrochloric acid in an hour and a quarter, the dextrin from beer was not completely transformed even after three hours.—J. S.

*Boiling with Hops, Shortening the Time of, and its Effect on the resulting Beer.* W. Wildisch. *Wechenschr. f. Brau.* 1897, 101—102.

Wort is boiled with hops for the following reasons:—

1. To destroy the diastase. This is effected before the boiling point is reached.

2. To sterilise the wort. This is effected after about 15 minutes' boiling.

3. To dissolve the soluble constituents of the hop. Hop tannin cannot be completely dissolved even by long boiling, and so the author recommends that the tannin be extracted separately, and added to the wort. Hops contain one hard resin and two soft resins: only the two latter are of value to the brewer, and they are very soon dissolved by the hot wort. If the hops have been previously soaked in hot water, this takes place in about 15 minutes. Since long boiling converts these soft resins into hard resins, it is avoided. Hops contain a certain amount of albuminoids, some of which are valuable for producing a "head" on beer; these are completely dissolved after about 10 minutes' boiling. As hop oil is volatile, the longer the worts are boiled, the less of this will they contain.

4. In order to precipitate albuminoids from the wort. About two-thirds of the wort albuminoids are thus separated. This takes place quickly, and if the boiling be prolonged, a portion redissolves.

5. The concentration of the wort is, of course, proportional to the time of boiling. However, if care be exercised in mashing and sparging, it is possible to dispense with a large amount of evaporation. The author is thus led to conclude that the boiling is frequently prolonged much longer than advisable, and considering that wort is very easily coloured by heating, and, being an acid liquid, must be decomposed by prolonged boiling, he is led to recommend a considerable shortening of the time of boiling. He considers that from 1 to 1½ hours are ample in all cases, but recommends that the wort be first boiled without hops, and that these, having been first soaked in warm water for two hours, be only boiled with the wort for 45—20 minutes.

—A. L. S.

*Worts, Boiling of.* C. H. Field. *J. Fed. Inst. Brewing*, 1897, **3**, 150—155.

THE main objects aimed at in boiling worts are stated to be: (1) the extraction of certain constituents of the hops; (2) the precipitation by heat, and by the combined action of heat and hop tannin, of a portion of the nitrogenous matters:

and (3) the fixation of the carbohydrate constituents of the wort, and the determination of the flavour or character of the beer. When an open copper was employed, the wort was found to acquire a distinctly harsh flavour, which is attributed to the oxidation of soft into hard resins; but this result is not obtained when a domed copper is used, and the latter is therefore preferable where delicately flavoured beers are required. With regard to the fixation of the dextrinous constituents, the higher the temperature at which the wort is boiled, the greater will be the stability of the product; and the conclusions arrived at are that, in boiling by steam, more actual units of heat are taken up, but the wort is in contact with lower temperatures, than when boiling by fire is adopted. In the author's opinion, however, equally good results are obtainable by either method of boiling, but where steam is used, a steady pressure of 50 lb. should be maintained throughout the boiling period. Where boiling under pressure is adopted, a much higher temperature can, of course, be obtained, but the circulation of the wort is probably much less rapid, and this is likely to lead to a greater increase in colour.—A. K. M.

*Alcoholic Fermentation, A Revolution in the Knowledge of.* A. Fernbach. *La Bière*, **5**, [3], 36.

REFERRING to the recently published researches of E. Buchner (this Journal, 1897, 156—157), the author remarks that we have now another instance of purely chemical action hitherto considered as inseparable from the physiological functions of living organisms. Zymase he considers as belonging to the diastase group, the rôle of which is extended by this discovery, and appears to be concerned in all the transformations erstwhile regarded as resulting from vital action. It seems as yet uncertain whether the discovery can have any practical value.—C. S.

*Wine, On the Oxidation and Souring of.* V. Martinand. *Comptes Rend.* 1897, **124**, 512—513.

THE author shows that the oxidation of wine can take place under certain conditions of acidity without the intervention of oxidising diastase. If, before oxidation takes place, the wine be extracted with ether, a substance having the properties of tannin is removed, and such wine, which is neutral to Helianthine, suffers no further change on oxidation.

—J. S.

*Wine, Composition of the, produced from Chinese and Japanese Species of the Grape Vine acclimatised in France.* L. Lindet. *Comptes Rend.* 1897, **124**, 569—572.

SINCE 1882, certain varieties of the grape vine (habitat, the cool and moist hilly districts of China and Japan) have been successfully acclimatised at Damigny, near Alençon, and at present are being introduced, by way of experiment, in other wine-growing districts. These vines are of a hardy and vigorous type, and apparently resist well the attacks of maladies to which the vine is subject.

The most important feature, however, is the early period of ripening of some of the varieties. For example "Precoce Caplat," a Japanese species, yields ripe fruit as early as Sept. 15—20; and several other kinds (V. Romaneti, V. Pagnucci) ripen about the same time. The fruit of most of the varieties is throughout (pulp included) of a dark red colour, and yields a very deep, full-coloured wine, the intensity of the coloration being 4—5 times as great as that of an average claret.

In the subjoined table, the chemical composition of some samples is given.

It will be seen that these wines, so far as alcoholic strength is concerned, are on a par with a light claret; but, on the other hand, contain about twice as much extract, tartar, tannin, &c.

According to expert opinions, these wines are, in some respects, superior to the deep-coloured wines of similar character, produced in Spain and Central France, and are especially suitable for replacing the latter for blending purposes.

*Grains, An Improved Method of Treating Brewers' and Distillers'.* F. B. Pike, Streatham Hill, Surrey. Eng. Pat. 6147, March 19, 1896.

THE grains are mixed with any meal, grain, or seed in sufficient proportion to absorb the moisture of the grains and render the mixture suitable for being readily worked into the condition of meal or prepared for baking and the like.—A. L. S.

*Beer specially adapted for Invalids.* J. C. Harvey, Knottingley, Yorkshire. Eng. Pat. 9783, May 8, 1896.

THE wort is fermented as far as possible so that no sugar remains in it, and saccharin is added to produce the necessary sweetness; also alcohol if necessary.—A. L. S.

*Brewing or Priming Ales or Beers, Manufacture of Material for Use in.* B. W. Valentin, Llanelli, Carmarthen. Eng. Pat. 13,262, June 16, 1896.

A STARCH transformation product is prepared containing large quantities of maltose and dextrin, and the syrup obtained by concentration *in vacuo* is heated until it becomes to some extent caramelised. The product thus obtained is slowly fermentable under the influence of the cask yeasts and gives continuous life and fullness to the beer.—A. L. S.

*Alcoholic Liquids, Impts. in, and Apparatus for Treating or Purifying, Rectifying, Aging, Deodorising, and Decolorising.* J. Y. Johnson, London. From The Electric Rectifying and Refining Company, New Jersey, U.S.A. Eng. Pat. 29,965, Dec. 29, 1896.

THE apparatus consists of glazed metal cylinders holding about 100 galls. of spirit, an ozone generator with suitable oxygen containers, and an air-pump. The whole is connected together by suitable tubing, with valves, &c. The spirit vessels are mounted on revolving platforms or on trucks and furnished with attenuating coils.

THE spirit to be treated is filled into the cylinders, the air exhausted, and the spirit brought to a cool temperature; ozone is then led into the vessel, and this acts on the spirit and produces the required purification.—A. L. S.

## VIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A.)—FOODS.

*Cooked Fish, The Composition of.* K. I. Williams. *Proc. Chem. Soc.* 1897, [178], 88.

TWENTY-TWO species of fresh fish and five species of preserved fish and oysters were examined after cooking.

DETERMINATIONS were made of the following constituents:—Water; carbon and hydrogen; nitrogen (total) by Ruffie's method; nitrogen by soda-lime combustion; ash; sulphur; phosphorus; fat; proteins; carbohydrates convertible into glucose; nitrates extracted by dilute alcohol; heats of combustion. The results are recorded in a series of tables.

*Grapes, Solubility of the Red Colouring Matter of. The Sterilisation of Fruit Juices.* A. Rosenstiehl. *Comptes. Rend.* 1897, **124**, 566—569.

THE conclusions are:—

1. In opposition to the accepted belief, it is found that the red colouring matter of grapes and other fruit is soluble in the juice *before* fermentation.

2. By the action of air the colouring matter is rendered insoluble.

3. This is one of the causes of the disease known as "goût de cuit."

4. It is possible so to preserve (sterilise) fruit juices, that the colour, flavour, and aroma of the fresh fruit are perfectly retained.—H. T. P.

*Meat Extract. Its Meaning as Food or Relish.* C. v. Voit. *Münchener Med. Wochenschr.*, **44**, 219—222.

THE author states that, in his opinion, meat extracts even when they do contain some added albuminoids are practically useless as food. But what renders them valuable in admixture with other foods is the large quantity of stimulating constituents they contain.—L. de K.

*Margarin, The Question of Colouring.* R. Henriques. *Chem. Rev. Fett-u.-Harz. Ind.*, **4**, [5], 68—70.

IT is pointed out that some ready means of distinction of butter from margarin—such as artificial coloration—is required for the protection of the consumer. Soxhlet's proposal to add phenolphthalein to margarin to act as a "latent" colour until developed by alkali is inefficacious owing to the ready solubility of the alkali compounds of this indicator in water. On the other hand dimethylamidoazo-benzene (the alternative "latent" colouring medium proposed), whilst not open to this objection, is already largely employed, under the name of "Butter Yellow" for heightening the tint of pale pure butters, so that its use for margarin would not facilitate the purpose in view. Moreover, being developed, not only by mineral acids, but also by the lower members of the fatty acid series, it is possible that the rose-red colour would appear concurrently with the formation of butyric acid as the butter or margarin aged, notwithstanding that von Buchka has not found this to occur in old butters coloured with this substance.—C. S.

*Margarin, Addition of Dimethylamidoazobenzene to.*  
A. Partheil. Chem. Zeit. 1897, 21, [27], 255-256.

Is place of phenolphthalein (Soxhlet), the author advocates the use of dimethylamidoazo-benzene for the production of the "latent colour," in the proportion of 1 grm. to 100 kilos. The required quantity is dissolved in oil and added to the margarin at the same time as the colouring matter, and before the butter flavour is imparted. Margarin thus prepared shows a rose colour on the addition of hydrochloric, sulphuric, or other mineral acids, or with potassium hydrogen sulphate when a few drops of alcohol have been added. On the other hand it gives no reaction with organic acids, even with acetic or oxalic acids. Thus the spontaneous appearance of a red colour points to the presence of a mineral acid.

According to Prof. Munk, the substance is completely harmless, and it has a further advantage over phenolphthalein in that it is only soluble in traces in water, whether made alkaline or acid; and thus cannot be washed out from the margarin, whilst on the other hand it is very much more soluble than phenolphthalein in oils or melted fats.—C. A. M.

## PATENTS.

*Butter and Cheese, Impts. relating to the Manufacture of.* Rudolf Baekhaus, Hesse, and Philipp Schach, Hesse. Eng. Pat. 1253, Jan. 17, 1896.

"A PROCESS for producing butter or cheese, the characteristic feature consisting in the preservation of the butterine," preferably by the addition of 10 per cent. of salt, after freeing it from butter milk as far as possible. When required for use the butter is melted down and made into an emulsion with milk poor in cream. From this emulsion butter may be churned or cheese separated in the usual way.—W. P. S.

*Grains, An Improved Method of Treating Brewers' and Distillers'.* F. B. Pike, Streatham Hill, Surrey. Eng. Pat. 6147, March 19, 1896.

See under XVII., page 456.

*Milk, Cream, and other Liquids, Impts. in or relating to the Preservation of.* H. Higgins, Cambridge. Eng. Pat. 7041, March 31, 1896.

THE liquid to be sterilised is placed in an air-tight vessel, on the top of which is an opening for the introduction of the liquid; this opening is closed by a suitable stopper. A second orifice is made in the top, to which is attached a tap or vent plug, protected by a filter of cotton wool and connected with a rod, which passes through a stuffing-box for opening and closing the tap. This tap is open during the sterilising process and is closed as soon as the process is completed. The receptacle is also provided with a draw-off cock, surrounded by a vessel containing an antiseptic fluid.

—W. P. S.

*Foods and other Perishable Goods, Impts. in or relating to the Preservation of.* H. Higgins, Cambridge. Eng. Pat. 7042, March 31, 1897.

THE improvement claimed consists of a sterilising chamber fitted with shelves for holding the vessels containing the article to be sterilised. There are doors at each end, and a vent, surrounded by cotton wool in a suitable manner.

The containing vessels are closed up, excepting a small hole, and are run into the sterilising chamber on trolleys.

They are finally sealed up with a mixture of paraffin wax and one or more of the following: French chalk, zinc oxide, kaolin, plaster of Paris, or chalk.—W. P. S.

*Coffee Substitutes from Grain, Impts. in the Process for Producing.* Kathreiner's Malzkaffee Fabriken mit beschränkter Haftung, Bavaria (through R. Hadden, London). Eng. Pat. 7880, April 14, 1896.

AN electrical current adapted to the kind and quantity of the grain used, is caused to act on the substances lying between the shell and the starch body of the grain during the preliminary soaking before roasting. By this means, the unpleasant taste caused by the decomposition of the nitrogenous matters during roasting is much lessened.

The soaking vessel is provided with a suitable mixing contrivance, and the wall of the vessel itself or portions of it, serve as a pole.—W. P. S.

*Bread, Biscuits, and the like, and a Compound therefor; Impts. in the Manufacture of.* W. W. Macadam, Brockley. Eng. Pat. 10,131, May 12, 1896.

THIS invention relates to a "diastatically prepared" extract of barley, wheat, maize, rice, oat, or rye, malt mixed with gluten (containing not more than 10 per cent. of starch), the said ingredients being thoroughly incorporated at a temperature of from 50° to 168° F. The above compound is used for mixing with flour for bread or biscuit making. From 4 oz. to 32 oz. diluted with water, may be added to each 280 lb. of flour. It is claimed that the yield of bread, &c. from a given quantity of flour is thus increased.—W. P. S.

*Butter, Margarine, and the like, and in the Method of Employing such Apparatus; Impts. in and relating to Apparatus for Testing.* R. Wells, Scarborough. Eng. Pat. 10,627, May 18, 1896.

See under XXIII., page 467.

*Tea, Impts. in the Manufacture of, Products from.* J. Davidson, Belfast. Eng. Pat. 11,060, May 21, 1896.

THE concentrated infusion of tea is, after the addition of preservatives, further evaporated until the residue becomes pasty or even solid, and may then be kept in bottles or jars.—W. P. S.

*Artificial Food for Swine, Cattle, and the like, An Improved Manufacture of.* S. P. Sørensen, Vejle, and A. P. Heyman, Copenhagen. Eng. Pat. 27,114, Nov. 28, 1896.

THE artificial food consists of a mixture of specially treated blood, mixed with molasses and corn. The blood is diluted with water, filtered, and heated to about 75° C., a dilute solution of alkali being added to keep the mixture fluid. Very dilute acetic acid is now poured in and the temperature increased to 100° C. Coagulation takes place when the comparatively solid mass may be removed from the liquid portion, pressed and dried. After grinding it is ready to be mixed with other constituents of the food.—W. P. S.

## (B.)—SANITATION; WATER PURIFICATION.

*Water, The Bacterial Purification of.* Percy Frankland. Proc. Inst. Civil Eng., Nov. 1896, 3-31.

IN April 1886, the author laid before the Institution the results of investigations on the bacterial purification of water which he had been carrying out by means of the then new bacteriological methods. In the present paper he gives a *resumé* of the progress of our knowledge during the past decade.

1. *Purification by Natural Processes.*—Numerous investigations have shown that the number of bacteria in a running stream becomes diminished during its natural flow. In seeking for an explanation of this, the remarkably destructive effect of *sunlight* on bacteria has been supposed to be a potent factor; but experiments by Procaecini have shown that the action of sunlight on microbes suspended in water

is confined to the upper layers, and that even Italian sunshine acting continuously for three hours in the height of summer failed to destroy a very large proportion of the microbes in water at a depth of only 50 centimetres.

Buchner, in experiments made on the Starnberger lake, near Munich, was unable to detect any bacterial effect at a depth of 5 feet, after  $4\frac{1}{2}$  hours continuous sunshine. Hence, insolation cannot be regarded as a material factor in the bacterial purification of water, especially in such an uncertain climate as that of England. Incidentally it is pointed out that the practice of storing filtered water in underground reservoirs is sound, as the influence of light, whilst having but a limited bacterial effect, would encourage the growth of green plants and lead to contamination of the water by decaying vegetable matter.

The purifying effect of *sedimentation*, first established by the author's experiments, has now been shown to be of great importance in connection with waterworks engineering. Thus, Thames water which, close to the West Middlesex Co.'s intake at Hampton, was found to contain 1,437 bacteria per c.c., after passing through one storage reservoir contained only 318, and after passing through a second reservoir only 177 bacteria per c.c. Researches carried out on some Continental rivers have shown that where the rate of flow is such as to permit sedimentation, as in flowing through lakes, the number of bacteria in the water falls, but when the flow is rapid, no falling off occurs, and disturbance of the mud at the bottom will often increase the number of bacteria.

Pettenkofer contends that the bacteria of river water are not removed by sedimentation, but rather by *oxidation* and the action of *algæ*. The available evidence favours the view that *algæ* do promote a purifying effect, and that the simultaneous existence of *algæ* and large numbers of bacteria are incompatible; but there is room for much more research in this connection.

*Dilution* with the purer water of springs and tributary streams is one cause of the diminution of bacteria in river water. The influence of summer temperatures in increasing the bacterial life of streams seems to be more than counterbalanced by other seasonal effects. Thus, the author has shown that the rivers Thames and Lea are purer in summer than in winter; doubtless due chiefly to the fact that during summer these rivers are largely fed by spring water, whilst in winter they are largely composed of water which has washed the surface of cultivated land.

Great diversity of opinion exists as to the influence of the movement of running water; the experiments hitherto published show that the growth of the ordinary water bacteria is favoured by agitation, but typhoid bacilli in sterilised water were destroyed. Probably further investigation would show that agitation is favourable to some and not to other kinds of bacteria.

Our present knowledge leads to the conclusion that *filtration through porous strata* is the most efficient of all natural processes of water purification, in illustration of which the author points to the fact that in the natural chalk water of the Kent Company he has frequently found less than 10 microbes in 1 c.c., whilst surface waters, such as the Thames at Hampton, contain from 1,000 to 120,000 organisms in the same volume.

2. *Purification by Artificial Processes.*—In connection with waterworks practice, the experiments of Karlinski and others are instructive, showing that the number of bacteria is much larger near the surface of a water basin, and diminishes as the depth increases; hence water companies should draw their supply from a considerable depth, but not low enough to disturb the mud at the bottom which often swarms with bacteria. The great importance of ample storage accommodation has been already referred to, and in the periodical cleaning of storage tanks, the muddy water should on no account be allowed to pass on to the filters; experiments made at the Altona waterworks showed that the settled mud may contain upwards of 17,000,000 bacteria per c.c.

As regards sand filtration, the author's early experiments showing that the number of bacteria in the filtrate depends upon the rate of filtration, have been verified by numerous investigators, and there has since been a gradual tendency

to reduce the rate. Thus at the London waterworks, the average rate per square foot per hour fell from 1.73 galls. in 1868 to 1.28 galls. in 1885. The new filters erected at Hamburg in 1892-93 were designed to deliver only 1.27 galls., but the more recent filters built at Tegel for the Berlin supply yield 2.05 galls. At Zürich, however, where the unfiltered lake water is of high quality, a filtration rate of 5.58 galls. per hour yields excellent results. Uniformity in the rate of filtration is of great importance, and great care must be taken not to disturb the layer of slime which forms upon the surface of the sand. The importance of this surface slime, first proved experimentally by Fränkel and Piefke, is now generally recognised, but it is necessary to have a sufficient depth of fine sand beneath it to obtain a filtrate of satisfactory bacterial purity. Thus Reinsch has shown that water which had passed through the slime layer still contained 29 per cent. of the bacteria present in the unfiltered water, but 40 cm. of fine sand beneath the slime layer reduced the remaining 29 per cent. to less than 1 per cent. As the power of arresting bacteria does not diminish with the age of a filter bed, scraping should only be practised when rendered necessary by a diminished yield, and the depth of fine sand must never be too far reduced. The German Imperial Board of Health has fixed 12 ins. as the minimum thickness of fine sand. The process of "airing" to increase the yield of a filter is strongly condemned.

The size of the sand grains has a great deal to do with the efficiency of filtration, and the Lawrence experiments have shown that with very fine sand having an "efficient size" of 0.09 mm. to 0.14 mm. and a depth of 4 to 5 ft. it is almost impossible to force through more than a very small percentage of the bacteria, even when no slime layer exists. The finest sand which will give the required yield should therefore be used. The relative merits of intermittent *versus* continuous filtration have formed the subject of extensive experiment at the Lawrence Station, but sufficient data has not been accumulated for a final conclusion to be drawn. The fact that frost in winter may render intermittent filtration inoperative, condemns it from a practical point of view. The Lawrence experiments have, however, taught the important fact that the more vigorous nitrification which goes on under "intermittent" conditions was no bar to the passage through the filter, in a living state, of all the bacteria experimented upon. Attention is finally drawn to the deleterious influence of frost. The exceptionally large number of bacteria found in some of the London waters on two occasions during the winters of 1886 and 1887 coincided with a very low temperature of the river water, and it is of great importance that the deleterious influence of frost, at a time of year when the more efficient filtration is needed, should be reckoned with and guarded against.

Mechanical analyses by Mr. Allen Hazen of the sand actually employed at many of the chief European waterworks, and the Regulations issued by the German Government in regard to the filtration of surface waters used for public water supplies, are given in two appendices.—L. A.

*Drinking Water, Analysis of.* G. Romijn. Nederl. Tijdschr. v. Pharm. Chem. en Tech. 1897, 87.

See under XXIII., page 467.

*Lead Poisoning, A Cause of: Artificial Flower Making.* J. B. Claret and P. Yvon. J. Pharm. Chim. 1897, 5, 375-379.

THE authors investigated the cause of the lead poisoning in the case of an artificial flower maker, whose work consisted in wrapping strips of paper (the end moistened on the tongue) round the stems of the flowers. An examination was made of all the papers used in flower making. Some do not contain lead, but a series ranging in colour from greenish-yellow to greenish-blue, contain the metal in the form of chromate. This may be extracted by caustic potash, and precipitated from the solution by acetic acid. In quantitative determinations the paper was burnt, and the lead converted into sulphate. The greater number of the papers examined, contained from 0.147-0.888 grm. of lead as chromate in each sheet (76 x 50 cm.). The authors

find that saliva (which is alkaline) is able to dissolve appreciable quantities of lead chromate, and to this property they attribute the absorption of the metallic poison.

—A. C. W.

#### PATENTS.

*Sewage Filters, Automatically Alternating the Delivery of Liquid to Two Chambers or Receptacles; Impts. in Apparatus for, particularly applicable to.* D. Cameron and F. J. Commis, Exeter. Eng. Pat. 3003, Feb. 10, 1896.

THE effluent from the filter which is in use rises into a well, and when the well is full the liquid overflows into a bucket fixed at one end of a rocking lever. This bucket, in filling, overweights the end of the lever, which descends, and in doing so, diverts the sewage on to another filter, at the same time opening a valve at the bottom of the well, and causing the effluent from the full filter to be rapidly discharged.—L. A.

*Sewage or Impure Waters, Impts. in the Manufacture of Materials or Compounds for Use in the Treatment of.* H. B. Sharp, Heaton Moor, near Stockport, Lancaster. Eng. Pat. 6132, March 19, 1896.

FINELY-GROUND mill or tap cinder is treated with sulphuric acid diluted with twice its weight of water, and the solution of ferrous sulphate is then further diluted with water and decanted from the insoluble residue. Part of the clear solution having been mixed with finely ground ore containing aluminium and iron, plus more sulphuric acid, is heated until the ore is dissolved, and, while boiling, the rest of the ferrous sulphate solution, to which sodium nitrate has been added, is run in. The "nitric acid gas" liberated during oxidation is condensed in water, and the solution of iron and aluminium sulphates is boiled down and allowed to solidify into blocks.—L. A.

*Sewage and Impure Liquids, Improved Apparatus for Filtering.* W. Birch, Manchester. Eng. Pat. 9374, May 4, 1896.

IMPROVEMENTS are referred to in the apparatus described in Eng. Pat. 4372 of 1890 (this Journal, 1891, 61). The endless filtering band is made of cotton cloth having a raised pile surface and occasional cross wires or plates to keep it of proper width and flat; two fixed guide plates keep the band in position. The cleansing roller presses the band upon the circumference of a drum covered with thick felt, and jets of water playing upon both surfaces of the band assist in loosening and removing the deposit.—L. A.

*Sewage and other Liquids, Impts. in the Purification of.* E. W. T. Jones and J. Garfield, Wolverhampton. Eng. Pat. 11,243, May 23, 1896.

THE filtering medium is composed wholly or in part of broken coal or bituminous shale. Preferably, the filter is composed entirely of coal, arranged as follows, from the bottom upwards:—6 ins. of about  $\frac{1}{4}$ -in. cube, 12 ins. of about  $\frac{1}{8}$ -in. cube, 30 ins. of about  $\frac{1}{16}$ -in. cube, 24 ins. of slack and fine coal.—L. A.

*Sludge or Deposit from Foul Waters and the like, Impts. in Apparatus or Means for Treating the.* H. W. Kearns, Manchester. Eng. Pat. 15,208, July 9, 1896.

A RECTANGULAR brick tank is divided into a serpentine channel by parallel walls, which extend alternately from one outside wall nearly to the opposite one. The tank is completely roofed in by brick arches springing from the dividing walls. On the bottom, rows of drain pipes are laid, covered by furnace ashes. One end of the channel communicates with a furnace and the other end with a chimney. The sludge is run on to the ashes, and the water is allowed to drain away. The furnace is then lighted, and the sludge is dried and burnt by the hot air and gases passing over it.—L. A.

*Town Sewage, Refuse, and the like; A New or Improved Method for the Treatment of, for the Destruction of Arimolecular and the Production of a Fertilising Compound.* S. de Petroff, Brussels, Belgium. Eng. Pat. 23,676, Oct. 24, 1896.

THE essential part of the process is the distillation of sewage with lime slags from dephosphorising processes, condensing the ammonia in a solution of acid calcium phosphate.—L. A.

##### PATENTS.

*Organic Substances, Impts. in or relating to Preservation of [by Hydroxyquinoline and its Salts].* A. J. Boulton, London. From F. Fritzsebe and Co., Hamburg, Germany. Eng. Pat. 7480, April 8, 1896.

HYDROXYQUINOLINE and its acid and neutral salts, as well as such soluble double salts as hydroxyquinoline potassium sulphate (quinosol), have an extraordinary preservative power. The body of a freshly killed rabbit, if sprinkled with, or preferably rubbed with, fossil meal containing 4 per cent. of quinosol, will remain sweet if only 1 gm. of the powder be used. Meat dipped in dilute quinosol solution becomes dry without becoming foul; eggs may be preserved in the solution, and liquids such as sugar solution, beer, &c., are preserved by the addition of 1 part in 10,000 to 1 in 100,000 of quinosol. Fruits may be preserved by embedding them in fossil meal containing quinosol. The patentee claims the above-described methods of preserving food, &c., by means of hydroxyquinoline and its salts. (See this Journal, 1896, 609 and 917.)—L. A.

*Disinfecting, Cleansing, and Deodorising Mixture, A Combined.* W. Hanlon, Innishannon, Cork, Ireland. Eng. Pat. 8712, April 25, 1896.

A MIXTURE of potassium permanganate and sodium carbonate.—L. A.

*Formaldehyde, Manufacture of Chemical Compounds of Starch and Dextrin with.* A. Classen, Aix-la-Chapelle, Germany. Eng. Pat. 1144, Jan. 15, 1897.

STARCH, dextrin, gum arabic, or any other similar substance is mixed with formaldehyde (40 per cent. solution) and heated under pressure, in order that the formaldehyde may react on the starch or other substance. About 24 hours at 124° C. is necessary, and this must be repeated with fresh formaldehyde. The excess of formaldehyde is removed from the finished compound by water, and the product dried at 100° C.

This product may be used for treating wounds, &c. when the use of formaldehyde itself is not possible.—A. L. S.

#### XIX.—PAPER, PASTEBOARD, Etc.

*Paper, The Action of Sunlight upon Size contained in.* W. Herzberg. Mitt. k. t. Versuchs-anst. zu Berlin, 14, [506], 309–316.

A SERIES of observations as to the action of sunlight upon resin-sized paper were made at the German Papier-Versuchsanstalt in 1889 (this Journal, 1890, 98–99). Five different samples of resin-sized papers, which were proved to be fully sized by Leonhardt's method, and upon which characters written in ordinary ink were clear and sharp, were exposed between two windows, upon which the sun shone only in the mornings, on June 13, 1888, and were taken out and again examined and tested on October 26, 1888, after four months' exposure, with the following results:—

No. 1. A white document paper, made from linen and cotton, without mineral loading. The ink characters slightly blurred, and the paper was not fully sized.

No. 2. A white foolscap, made from linen, cotton, and wood cellulose, without mineral loading. The ink characters blurred, the thicker strokes sinking into the paper, which was only about half sized.

No. 3. A yellowish common writing paper, made from chemical and mechanical wood pulp, and containing 13.5 per cent. of ash. The ink characters remained clear, the paper being fully sized.

No. 4. A white foolscap, made from straw, wood cellulose, cotton, and linen, containing 13.8 per cent. of ash. All the ink characters blotted and the thicker ones sunk into the paper. The paper was only about half sized.

No. 5. A document paper made from unbleached linen, without mineral loading. The results were similar to those in No. 2.

No. 5 was unaltered in appearance; Nos. 1, 2, and 4 were turned slightly brown, and No. 3 was distinctly brown.

These observations led to experiments in which resin- and animal-sized papers were exposed to light to note its effect upon the size, and the following results were obtained:—

No.	Name of Size.	Composition of Pulp and Amount of Ash.	Observations made on the						Appearance of Paper on Dec. 1st, 1891.	
			1st Dec. 1889.	1st Jan. 1890.	1st Feb. 1890.	1st Mar. 1890.	1st April 1890.	1st Dec. 1891.		
I.	Resin	Wood cellulose and straw cellulose. Ash 18.8 per cent.	Characters clear and sharp, hardly to be seen at back.		Characters clear, but show through a little more.	Characters clear, but thick strokes show through.	Characters blot slightly, and show through strongly.	Characters blot and sink in.	Slightly brown.	
II.	"	Cotton and linen, with addition of straw and wood. Ash. 16.8 per cent.	No observation on this date.	Characters clear, but thick ones visible on back.	Characters blot, show through, and thick strokes sink.	Characters, especially thick ones, blot, and mostly sink in.		All characters totally blot, and all show through.	Very brown.	
III.	Resin and animal.	Cotton, with a little linen. Ash. 1.3 per cent.	Characters are clear and sharp, and not visible at the back.						All characters blot, but are not visible on the back.	Brown.
IV.	"	Cotton and linen, with some straw and wood. Ash. 18.5 per cent.	Characters clear and sharp, not visible at the back.						Characters blot slightly, and some show through.	Slightly yellow.
V.	Animal	Linen, with a little cotton. Ash. 3.5 per cent.	Characters clear and sharp, slightly visible at back.						Characters clear and sharp, but a few thick ones show inclination to blot.	"
VI.	"	Cotton and linen. Ash. 1.5 per cent.	Characters clear and sharp, and visible at the back.						All characters blot and show through, the medium and thick strokes sink through.	"

No. II. in the table was specially sized for exposure, by soaking an entirely unsized plate-paper in an ethereal solution of resin; thus it contained only resin size. This sample lost its size very rapidly. It will be observed from the table that the animal-sized papers also deteriorated, and this being contrary to the observations of other experimenters it was determined to expose some papers to the influence of the atmosphere, but to cover parts of the samples from the action of light. At the end of the experiment the covered parts of the resin-sized papers were proved to have kept their size, but the covered parts of the animal-sized papers had deteriorated. This proves that in the case of resin-sized papers, it is the light which causes the deterioration, but with animal-sized papers it is evidently some other destructive agent.

Samples of both resin- and animal-sized papers were exposed to a temperature of 98° C. for some time, but did not lose their size even when the papers had been heated so long that they crumbled to pieces on handling; so that heat has no effect on the size.

During last year other experiments were made by different experimenters (Papier Zeit. 1895, No. 94—99), with the following results:—

Wolesky and Haase ascertained from their observations:—

1st. That the composition of the pulp does not play any part in the deterioration of the size by sunlight.

2nd. That animal-sized papers are not much affected by the light.

3rd. That resin-sized, highly glazed papers show a considerable deterioration, the ink characters blotting and going through after three to four weeks' exposure.

4th. That unglazed resin-sized papers resist the action of light slightly more than glazed, but the resistance only affects the result by a few days.

5th. That only the side exposed to the sun loses the size.

Liesegang obtained the same results as the Versuchsanstalt obtained in 1888. Paper which did not contain ground wood-pulp deteriorated, but paper containing ground wood did not deteriorate on exposure to sunlight.

On comparing these results some contradictions may be noticed:—

1. Wolesky and Haase and the later experiments of the Versuchsanstalt show that the composition of the pulp has no influence on the deterioration of the size, while Liesegang and the former experiments of the Versuchsanstalt show that ground wood does affect the deterioration.

2. The animal-sized papers were not altered in Wolesky and Haase's experiments, but in the experiments conducted by the Versuchsanstalt they completely lost their size.

It is hardly possible to state the exact reason why contradiction No. 1 should occur. By further experiments it was, however, shown that resin- and also animal-sized papers lost their size on exposure to sunlight, whatever their composition, if exposed for a sufficient time.

Different reasons have been advanced to explain the loss of size. Wolesky and Haase suppose that the resin enters into combination with the fibres of the paper, and that the sunlight decomposes the compound thus formed. They say that if the resin mechanically filled the spaces between the fibres, the light would have no effect; but this supposition may be wrong, as it has been observed that when resin is exposed to sunlight it cracks and numerous flaws appear, and this may be what takes place in the paper.

Liesegang is of opinion that the deterioration is caused by chemical action. He observed that a paper which had been exposed to sunlight on one side only, when dipped into an alcoholic solution of pyrogallol, turned an intense orange-brown colour on the exposed side, the other side remaining almost colourless. Papers containing ground wood did not show any difference between the sides on being treated in the same manner, and therefore Liesegang came to the opinion that ground wood acts in the same manner as the sodium sulphite acts with the pyrogallol in photography: the sodium sulphite, being more easily oxidised than pyrogallol, is oxidised first, and prevents the solution going speedily brown. Liesegang says that in the same manner the light acts first upon the ground wood in the paper before taking effect upon the size.

Dr. Burkhardt's opinion is as follows:—The sizing with resin is a purely physical occurrence, the size being fixed between the fibres in a finely-distributed state, and by the influence of sunlight the resin is decomposed, and its sizing power lessened. On animal-sized papers no deterioration by sunlight can be proved.

A fact that may have some bearing is, that when resin is exposed to light it becomes insoluble. On the papers Nos. 1. to IV. in the table, before exposure, a distinct ring of resin was formed by dropping a little ether on them, and allowing it to evaporate; but no such ring could be obtained after exposure.

With reference to the deterioration of animal-sized papers in the parts covered from the light, it is probable that the deterioration was produced as follows: In consequence of the change of temperature and moisture in the air, fine cracks are produced in the thin coat of animal size, through which cracks the ink penetrates. This supposition is corroborated by the manner in which the ink characters spread. The same result is observed when an animal-sized paper is rubbed between the hands and afterwards written upon.—S. P. E.

#### PATENT.

*Paper Machines, New or Improved Apparatus for Cleaning and Sorting the Water derived from.* O. Schmidt, Audritz, near Graz, Austria. Eng. Pat. 6853, Mar. 28, 1896.

An arrangement of tanks and connecting pipes for mechanically treating, on the continuous flow system, the water from a paper machine, so as to intercept and return the pulp to the paper machine, eliminate the greasy scum, and fit the clear water for use in the rag engines.—L. A.

### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Hydrogen Peroxide, Preservation of.* Sunder. Bull. Soc. Ind. Mulhouse, 1897, 95–96.

THE addition of a small quantity (up to 2 per cent.) of alcohol or ether is effective in retarding the decomposition of hydrogen peroxide solutions. A solution of hydrogen peroxide at 5.6 volumes, reckoned to a litre of 100, and containing the amount of alcohol above stated, tested 96.2 per cent. after standing for two days, and 48.2 per cent. of its original strength after 84 days, whilst, without this addition the numbers obtained were 78.6 and 1.3 respectively.—T. A. L.

*Note on the Preceding.* G. Freyss. Bull. Soc. Ind. Mulhouse, 1897, 97.

THE author reports that he has examined the method proposed by M. Sunder, and can testify to its efficiency. The titrations were made with potassium permanganate in a cold solution, acidified with sulphuric acid, under which conditions absorption of the permanganate is not due to oxidation of the alcohol.—T. A. L.

*Alkaloids isolated from a Species of Jaborandi, Two New.* A. Petit and M. Polonovski. J. Pharm. Chim. 1897, 5, 369–370.

By submitting 1 kilo. of the leaves of *Pilocarpus spicatus*, a species of jaborandi, to the treatment generally employed for that plant, the authors obtained 3 grms. of a mixture of bases, the nitrates of which, crystallised from alcohol, melted at about 140° C. The mixture of nitrates, on shaking with caustic soda and chloroform, gives up one base to the solvent, whilst the other remains in the form of a salt. The former, for which the name pseudo-jaborine is adopted, is a colourless syrup with a very alkaline reaction, soluble in water, alcohol, and chloroform; the base and its salts are inactive. The nitrate crystallises from alcohol in large thin plates, melting at 158° C.; the hydrochloride forms small prisms with the melting point 222° C. The second base, pseudo-pilocarpine, is similar to pilocarpine, but has no action on polarised light. Its nitrate crystallises

in small needles which melt at 142° C., its hydrochloride in small prisms, very soluble in water and alcohol, and melting at 198°–199° C.—A. C. W.

*Pilocarpine and Pilocarpidine.* A. Petit and M. Polonovski. Journ. de Pharm. 1897 (6), 5, 370, 380.

THE authors find that pilocarpine and pilocarpidine may be readily separated in a state of purity from the other alkaloids of jaborandi by reason of the property they possess of forming a definite compound with solutions of fixed alkalis, from which they are not washed out by chloroform, while the other alkaloids are removed; after this treatment, on neutralising the alkaline solutions with an acid and liberating the two alkaloids with ammonia, they are readily removed by means of chloroform.

Although the isolation of these two bases is thus relatively easy, their separation from each other is not so simple. The solubility of the two nitrates is so nearly identical, that fractional crystallisation of these salts is useless. It is found, however, that by crystallising the mixed hydrochlorides, an excellent separation is obtained; so that by three successive crystallisations from alcohol, the greater part of the pilocarpine hydrochloride is obtained in a state of purity. The pilocarpidine in the mother liquors is recovered in two crystallisations from alcohol. Pilocarpidine may also be readily obtained from pilocarpine by treating that base with sodium ethylate.

One gram. of metallic sodium is dissolved in 30 grms. of absolute alcohol, 3 grms. of pilocarpine dissolved in the same amount of alcohol are added, and the mixture heated on the water-bath for several hours. When reaction is completed the alcohol is distilled off and the alkaline residue extracted with chloroform, which removes the decomposition products. It is re-dissolved in hydrochloric acid, the base liberated with ammonia, and removed by means of chloroform or ether.

At present, pilocarpine has been isolated solely in the form of an amorphous syrup, but the authors hope ultimately to obtain it in a crystalline condition. It is readily soluble in water, alcohol, or chloroform (Hardy and Calmels state that it is but slightly soluble in the last solvent), less soluble in benzene, and almost insoluble in petroleum ether. It obstinately retains traces of the solvent by which it has been extracted, and requires prolonged exposure over sulphuric acid to render it perfectly dry. A 2 per cent. solution at 18° C. has the optical rotation  $[\alpha]_D = +106^\circ$ , and the salts are also strongly dextro-rotatory. The nitrate crystallises from water in large transparent prisms, from alcohol in small prismatic needles, melting at between 177–178° C. Its optical rotation in a 2 per cent. solution at 18° C. is  $[\alpha]_D = +82.2^\circ$ . The amount of combined nitric acid determined by titration, corresponds to the formula  $C_{11}H_{16}N_2O_5.HNO_3$ . The solubility in water at 18° C. is 1 in 6.95; in 95 per cent. alcohol at the same temperature, 1 in 146.

The pilocarpine hydrochloride occurs in transparent prisms melting at 200° C. It contains no water of crystallisation. Its optical rotation in 2 per cent. solution at 18° C. is  $[\alpha]_D = +91^\circ$ . The amount of combined hydrochloric acid agrees with the formula  $C_{11}H_{16}N_2O_3.HCl$ . Its solubility in water at 18° C. is 1 in 0.4; in 95 per cent. alcohol, 1 in 10.4. The hydrobromide, sulphate, salicylate, and picrate were all obtained in a crystalline form. Although Hardy and Calmels have stated that four gold salts may be obtained according to varying conditions, the authors have only been able to prepare two, the acid monochloroaurate,  $C_{11}H_{16}N_2O_3.HClAuCl_4$ , melting, when anhydrous, at 130° C.; and its modified form, melting at 167° C., and not at 86° C. as stated by Hardy and Calmels; this has the formula  $C_{11}H_{16}N_2O_3AuCl_4$ . The first-named salt is obtained by the interaction of pilocarpine and gold chloride in the presence of hydrochloric acid. It forms lemon-yellow crystals containing 1 mol. of water of crystallisation. The modified form is obtained by treating this salt plentifully with boiling water. The solution becomes markedly acid and begins to deposit the modified chloroaurate in the form of small bright yellow lamellae.

Pilocarpidine closely resembles pilocarpine in its chemical reactions, but differs in physiological effects, in the melting

points of its salts, and in its optical properties; the combinations of its salts with the fixed alkalis, on account of the formation of pilocarpic acid are slightly levo-rotatory.

As usually obtained, pilocarpidine is a white syrup, but from the pure nitrate the authors have obtained it in large oblique prisms, very hygroscopic, and soluble in water, in alcohol, and in chloroform. The optical activity of a 2 per cent. aqueous solution at 18° C. is  $[\alpha]_D = +50^\circ$ . The salts are all dextro-rotatory, but the combination with fixed alkalis, as stated above, becomes levo-rotatory. The nitrate is obtained by crystallising from water in large prisms or transparent tablets. From boiling alcohol it is deposited in brilliant white scales melting at 158° C. Its optical rotation in a 2 per cent. solution at 18° C. is  $[\alpha]_D = +38.5^\circ$ . The formula is found to be  $C_{11}H_{16}N_2O_2.HNO_3$  and its solubility in water is 1 in 8.04; in 95 per cent. alcohol 1 in 135, both at 18° C. The hydrochloride crystallises from a mixture of alcohol and ether in brilliant lamellae, containing approximately  $\frac{1}{2}$  a mol. of water of crystallisation. It melts at 124° C., and is completely dehydrated at 100° C. when it melts at 161° C. The determination of the hydrochloric acid in the dry salt agrees better with the formula  $C_{11}H_{16}N_2O_2.HCl$  than with  $C_{10}H_{14}N_2O_2.HCl$ . The hydrobromide, salicylate, and picrate were all obtained in a crystalline state. The chloro-auroates corresponded precisely with the similar salts of pilocarpine. The authors find, moreover, that the precipitate obtained on treating pilocarpidine hydrochloride with gold chloride is not soluble in excess of that salt. In this their results are diametrically opposed to the statements of Merck, Hardy and Calmels, and Harnack, who state that it is soluble. The salt melts at 160° C., and contains no water of crystallisation. The formula is  $C_{11}H_{16}N_2O_2.HCl.AuCl_3$ . To boiling water this salt gives up the molecule of hydrochloric acid, and the resulting modified chloro-auroate,  $C_{11}H_{16}N_2O_2.AuCl_3$ , crystallises in bright yellow lamellae melting at 190°.—J. O. B.

#### *Oil of Celery, High-Boiling Constituents of.*

G. Ciamician and P. Silber. Ber 30, 492—591.

In a previous paper (Ber. 29, 1799) on the oil of *apium graveolens* L. (oil of celery), the authors showed that it contained limonene. That it did not consist wholly of this was at once evident from the smell, which pointed to the presence of a non-terpene-like substance. Commercial oil of celery, however, does chiefly consist of terpenes as it appears that a very small proportion of the odouriferous principle will scent a large quantity of the oil. The examination of the higher boiling portion of oil of celery showed that it contained a terpene, probably  $C_{15}H_{24}$ , palmitic acid and phenolic substances, a lactone  $C_{12}H_{18}O_2$ , and an acid  $C_{12}H_{14}O_2$ . The lactone is present as such in the plant whilst the acid is only obtained after saponification. Palmitic acid and the phenols are only present in very small quantities, and the terpenes are found principally in the first portions of the distillate. The "latter runnings" obtained on distilling oil of celery were extracted with cold dilute potash (2½ per cent.) to remove palmitic acid and phenols, and the residual oil which forms the bulk, was treated with twice its weight of caustic potash solution of 25 per cent. strength and heated in an oil bath under an inverted condenser. The oil unacted on, was removed with ether and gave results on analysis corresponding with the formula  $C_{15}H_{24}$ . It boils at 262°—269° C., and forms about 80 per cent. of the total "latter runnings." The alkaline liquid contains the potash salts of two acids, which the authors have termed sedanollic acid  $C_{12}H_{16}O_2$  and sedanonic acid  $C_{12}H_{14}O_2$ . The former is an oxyacid, and is converted with very great ease into the corresponding lactone, sedanolide  $C_{12}H_{18}O_2$ . After acidifying the alkaline solution, extracting with ether, and distilling off, the oil remaining, is shaken with three times its weight of sodium carbonate, when the sedanollic acid dissolves and the sedanonic acid yields the lactone, which is extracted with ether and distilled under 17 mm., when 80 per cent. passes over at 183°—185° C. In order to obtain sedanollic acid, the lactone is carefully treated with caustic potash and poured into cold dilute sulphuric acid. After filtering off, taking up with ether and precipitating with petroleum ether, the final purification of the sedanollic acid is effected by

precipitating it repeatedly from benzene or ether with petroleum ether, avoiding a rise in temperature. The acid crystallises in white needles melting at 88°—89° C. As already observed, it is very easily converted into sedanolide especially on distilling the acid from a small retort. The lactone boils under 17 mm. at 185° C., and forms a thick colourless oil, smelling strongly of celery. Sedanollic acid is contained in the alkaline solution referred to above, obtained by digesting the saponification product of oil of celery with sodium carbonate. The acid separates from benzene in white crystals and melts at 113° C. The substance is an unsaturated ketonic acid. It forms an unstable hydrazone with phenylhydrazine, melting at 130°—131° C. The oxime crystallises from benzene in white shining crystals and melts at 128° C.—T. A. L.

#### *Hydroxycamphor.* O. Manasse. Ber. 30, 659—670.

By the reduction of camphor-*o*-quinone, the author has obtained an oxycamphor which has all the characteristics of a ketone alcohol, and differs from all previous products similarly designated. The substance has one of the two following formulæ:—

and differs in its physiological properties from campherol—

to which, of the oxycamphors hitherto known, it comes nearest in its chemical and physical properties. The camphor quinone was obtained by boiling the solution of nitrosocamphor in bisulphite with dilute sulphuric acid, an 80 per cent. yield being obtained. The reduction is carried out by dissolving the quinone in ether, adding dilute sulphuric or hydrochloric acid, and running in zinc dust suspended in water until the solution is decolorised. After filtering, drying, and distilling off the ether, the product is purified by steam distillation. Other reducing agents (aluminium amalgam, zinc dust and acetic acid) give the same result, and under proper conditions the reaction is a quantitative one. The new substance melts, when pure, at 205° C., it dissolves to a 2 per cent. solution in cold water, and can be precipitated almost quantitatively from its aqueous solution by salt. Its aqueous solution turns the plane of polarisation to the right (specific rotation = 9.5°).

When treated with chromic acid, the substance yields camphorquinone, whilst under the action of hydrogen peroxide it gives camphoric acid. Hydroxycamphor is of pharmacological interest, owing to the fact of its being a soluble camphor derivative, and it possesses the following properties:—It reacts neutral, and a 2 per cent. aqueous solution is without action on albumin, although globulin is thrown down as a flocculent precipitate. On cold-blooded animals (frog), hydroxycamphor has a similar action to camphor, producing brain paralysis, together with a curare-like paralysis of the motor nerve fibres. With warm-blooded animals, the only visible effect is a decreased respiration, and the lowering of the excitability of the respiratory organs has given good results in certain cases. The blood pressure as well as the heart's action are not affected. Hydroxycamphor has proved an active remedy in different forms of malady involving difficulty of respiration.

—T. A. L.

#### *Antipyrine, Combinations with Phenol; Constitution of.* G. Patein. Bull. Soc. Chim. 1897, 17, 314—316.

The author has previously shown that antipyrine combines with phenols, forming compounds in which both constituents retain their properties, so that they are united not through a carbon atom but through one of the trivalent nitrogen atoms, which passes over into the pentavalent condition. He has already indicated, on theoretical grounds,

that it is nitrogen atom No. 2 that acts as the intermediary. He now compares antipyrine with monomethylphenyl-pyrazolone, in which the nitrogen atom No. 1 is identical with that of antipyrine, whilst the second atom is differently placed. He finds that the pyrazolone derivative in no case combines with phenols, and hence concludes that it is by nitrogen atom No. 2 that the antipyrine may be united to them. The combination of antipyrine with the phenols is irreconcilable with E. von Meyer's formula for that substance (J. prakt. Chem. **54**, 177; see also this Journal, 1896, 670).—W. G. M.

*Anethol, Derivatives of; Chlorine Addition and Substitution Products.* G. Darzens. Comptes Rend. 1897, **124**, 563—565.

*Anethol Dichloride.*—Prepared by slowly mixing cooled solutions of anethol and chlorine respectively in carbon tetrachloride, and subsequently removing the solvent by distillation under reduced pressure. The dichloride is a mobile, amber-coloured liquid, which cannot be distilled, even *in vacuo*, without suffering decomposition into HCl and chloro-anethol.

*Mono-Chloro-Anethol* ( $C_6H_4.OCH_2.C_2H_4Cl$ ).—The preceding compound is distilled, the distillate washed with weak alkali, and fractionated. The chloro-derivative possesses an odour closely resembling that of anethol. It boils, without decomposition, at  $258^\circ C.$  and solidifies at  $0^\circ C.$  The solid substance melts at about  $6^\circ C.$  Specific gravity at  $0^\circ C. = 1.350$ .

*Chloro-Anethol-Dichloride.*—Forms small white crystals, melting at  $35^\circ C.$ , and soluble in all organic solvents. It is obtained when carbon tetrachloride solutions of mono-chloro-anethol and of chlorine are mixed, and allowed to evaporate spontaneously.

*Chloro-Anethol Dibromide.*—Prepared on the same lines as the corresponding dichloride, is obtained in small, white crystals, which melt at  $45^\circ C.$ —H. T. P.

*Saccharine and its Preparation.* Jan Burda. Časopis pro průmysl Chemický, 1897, **7**, 9.

TOLUENE is best sulphonated, with continuous agitation, by 4 parts of sulphuric acid of  $66^\circ B.$ , to which several per cents. of fuming acid, containing 20 per cent.  $SO_3$ , have been added. After pouring the product on  $1\frac{1}{2}$  parts of ice, the separated ortho acid is converted by means of chalk into the calcium salt, and this, by treatment with soda, into the sodium salt.—J. T. C.

## PATENTS.

*Pharmaceutical Substance [Thyroid Extract], Impts. in the Manufacture of.* Farbwerke vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 9576, May 5, 1896.

THE active principle of thyroid glands, iodothyrene, contains iodine, the activity of its preparations being in proportion to the amount of iodine contained in them. This patent therefore claims the improvement on the processes described in Eng. Pats. 12,295, 1895 and 20,827, 1895 (this Journal, 1896, 470 and 740), which consists in boiling the glands with dilute acid or alkalis until the residue contains the greatest or the least quantity respectively of iodine. The process for the isolation of iodothyrene which consists in digestion of the glands with artificial gastric juice and extraction of the residue by alcohol, is claimed, together with processes for the separation of compounds of iodothyrene with globulin and serum albumin by digestion of the glands with dilute solutions of common salt, filtering, and precipitation by boiling the filtrate with a little dilute acetic acid, with or without the previous separation of the globulin compound by dilution or action of carbon dioxide. The patent also claims the process for the isolation of iodothyrene from its albumin compounds before described by the processes previously claimed, and lastly, the globulin and serum albumin double compounds as new products.

—A. C. W.

*Cinnamic Aldehyde, Impts. in the Manufacture or Production of.* C. F. Boehringer and Söhne, Wadthof, Germany. J. Y. Johnson, London. Eng. Pat. 10,003, May 11, 1896.

THE production of cinnamic aldehyde by the condensation of benzaldehyde and acetaldehyde at a low temperature by means of a concentrated alkali solution, is claimed. The alcoholic solution of the aldehydes cooled to  $-10^\circ$  is agitated with a 25–30 per cent. caustic soda solution previously cooled to the same temperature. Fermentation of resin is thus avoided.—A. C. W.

*Piperidine and its Homologues, Manufacture of Derivatives from.* [Compounds with Phenols and Acids.] J. Turner and Co., Ltd., Queensferry; P. Schidrowitz and O. Rosenheim, London. Eng. Pat. 11,061, May 21, 1896.

IN this patent are claimed the compounds produced by the action of piperidine or its homologues on guaiacol, hydroquinone, tannic acid, pyrogallol, nitro-phenols, 1:2:4 dinitro- $\alpha$ -naphthol, *m*-nitro-benzoic acid, 1:3:5 dinitro-benzoic acid, with the process which consists in bringing about the condensation with or without a solvent and with or without the application of heat.—A. C. W.

*o-Sulphamine Benzoic Acid Alkyl Esters, and Anhydro-o-Sulphamine Benzoic Acid [Saccharine], Impts. in the Manufacture of.* Chemische Fabrik von Heyden, Radebeul, Germany. Eng. Pat. 1164, Jan. 15, 1897.

THIS patent claims the manufacture of the esters of *o*-sulphamine benzoic acid by heating the acid in alcoholic solution with a comparatively small quantity of mineral acid, the manufacture of the pure acid by oxidation of *o*-toluene sulphonamide or a mixture of the *o*- and *p*-compounds in alkaline solution by potassium manganate, permanganate, or other oxidising agent, and in the case of the mixture separation of the acids by fractional precipitation, and also claims the process for producing anhydro-*o*-sulphamine benzoic acid, which comprises the two above processes and subsequent formation of the anhydro acid according to known methods. In the first operation the alcohol must be as free as possible from water and concentrated sulphuric acid or hydrochloric acid gas is used.—A. C. W.

## XXI.—PHOTOGRAPHY.

*Metol.* L. Paul. Zeits. f. angew. Chem. 1897, 171—174.

THIS product, which is used as a photographic developer, is the sulphate of methyl-*p*-amidophenol, and is said to be obtained by methylating *p*-amidophenol. The author, however, concludes from his experiments that it is not produced by the direct methylation of *p*-amidophenol, and he obtains it by an indirect method, described later. For the preparation of *p*-amidophenol, he heats 250 grms. of *p*-nitrophenol, 45 grms. of hydrochloric acid ( $20^\circ B.$ ), and 500 c.c. of water in an iron vessel, provided with an agitator, to  $98^\circ C.$ , and adds gradually, in portions of 15 to 20 grms., about 400 grms. of iron borings, so long as a vigorous reaction takes place. The whole is then boiled for half an hour and extracted with about 2 litres of water and 25–30 grms. of sodium carbonate. The filtered solution deposits *p*-amidophenol on cooling and the mother-liquor is used for the next extraction, which is continued as long as *p*-amidophenol crystallises out on cooling. The yield is 140 grms., corresponding to 71 per cent. of the theoretical. By boiling it with methyl alcohol and sulphuric or hydrochloric acid the base remains unaltered. The same is the case if *p*-amidophenol hydrochloride be heated in an autoclave with methyl alcohol to  $150^\circ$ – $160^\circ C.$  By the action of methyl chloride under pressure on the base, higher methylated products are formed. The methyl chloride was obtained by passing hydrochloric acid gas through methyl alcohol and zinc chloride, and condensing the gas in methyl alcohol cooled with ice. Metol can, however, be obtained by boiling for about an hour in aqueous solution, two molecules of *p*-amidophenol and one molecule of chloroacetic acid. On cooling, *p*-hydroxyglycine crystallises

our, which on heating turns brown at 200° C., begins to melt at 220° C., and is completely melted at 245–247° C., when it decomposes into carbonic acid and metal according to the equation—

The metal obtained melted at 86° C. and gave the characteristic nitroso compound.—T. A. L.

*Indigo Salt, Action of Light on Kall's.* E. Kopp.  
Bull. Soc. Ind. Mulhouse, 1897, 87.

See under IV., page 132.

#### PATENTS.

*Photographic Emulsions, Imps., in.* [Addition of White of Egg.] H. Wandrowsky, Cologne-Ehrenfeld, Prussia. Eng. Pat. 5922, March 17, 1896.

The addition of white of egg to emulsions prepared with gelatin, starch, gutta-percha, &c., which is made insoluble after the emulsion has been spread on glass or paper, is claimed.—A. C. W.

*Uranium Intensifiers and Reducer, Improved, as applied to Photographic Negatives and Positives.* A. Hill and The Cresco-Fylma Co., Ltd., London. Eng. Pat. 10,972, May 12, 1896.

The patent claims the use of uranium acetate in combination with a suitable acid and potassium ferricyanide, for intensifying and reducing negatives and positives; the same mixture, with the addition of strontium nitrate or potassium sulphocyanide, for toning bromides and transparencies; and lastly, tabloids containing amylacetate celluloid, uranium acetate, potassium ferricyanide, and citric acid.—A. C. W.

*Colouring Photographs, Improved Means for, suitable also for Dyeing and Printing.* J. A. Michel Dausac and L. Chassagne, Paris. Eng. Pat. 18,131, Aug. 15, 1896.

The following five mixtures are claimed, and their application to photographs on any support:—

*Albumin for Shadows.*—Dissolve 200 grms. of blood albumin in 500 grms. of water at 37–40° C.; add to 500 grms. of water, 1 gm. each of the chlorides of platinum, sodium, palladium, ammonium, iron, chromium, cobalt, gold, tin, barium, nickel, strontium, cadmium, mercury, and silver. In a 125-c.c. flask put 10 grms. of cocaine hydrochloride; fill up with water. Let each mixture stand 24 hours. Add to the first solution, 5 grms. of sodium sulphate, 1 gm. of oxalic acid, and 0.25 gm. of corrosive sublimate; take 100 grms. of this mixture, whip up in it a fresh egg and a pinch of haemoglobin, then mix with the remainder of the albumin, and add the cocaine solution. Finally, mix with the solution of the chlorides, and let stand 24 hours.

*Albumin for Reliefs.*—Take half of the shadows albumin, add 1 gm. of picric acid, 1 gm. of chromic acid, 0.1 gm. of formic acid, and incorporate with a mixture of 125 grms. of water, 5 grms. of sodium chloride, 1 gm. of platinum chloride and 50 grms. of fresh casein.

*Blue Pigment.*—To 100 c.c. of the shadows albumin, add a solution of 1 gm. of sodium chloride in 1 kilo. of water; to 100 grms. of this, add 5 grms. of indigo carmine and 5 grms. of oxalic acid; then mix with the remainder.

*Green Pigment.*—Add 50 c.c. each of shadows and relief albumin to a solution of 1 gm. of sodium chloride in 1 kilo. of water. In 50 grms. of the mixture dissolve 1 gm. each of the chlorides of nickel, chromium, and copper, 1 gm. of sulphate of copper, and 1 gm. of copper nitrate. In a second 50 grms., dissolve 1 gm. of picric acid and 1 gm. of indigo carmine. Mix the two 50-grm. solutions, and then add to the remainder, agitate, and let stand.

*Red Pigment.*—Add 100 c.c. of albumin for reliefs to a solution of 1 gm. of sodium chloride in 1 kilo. of water. To 50 c.c. of this solution add 1 gm. of each of the following: cinabar, iron chloride, iron sulphate, uranium acetate. Add this mixture to a solution of 5 grms. of ammonium sulphocyanide in a second 50 c.c., then add 30 grms. of fresh casein, mix with the remainder, and let stand.

The mixtures should be kept several months before use. The process consists in washing the photograph with the liquids in the following order: shadows albumin, relief albumin, blue pigment, shadows albumin, green pigment diluted with 10 volumes of shadows albumin, reliefs albumin, red pigment diluted with reliefs albumin, shadows albumin; the albumin solutions being diluted for use with 10 volumes of 0.1 per cent. sodium chloride solution. The photograph is not washed between the different applications. —A. C. W.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Phosphorus, Apparatus for Granulating.* A. Harpf.  
Zeit. physikal. u. Chem. Unterr. 1896, 9, 286.

This apparatus is constructed on the principle of a shot tower. It consists essentially of a tube *a*, of well-annealed glass 700 mm. long and 45 mm. in diameter, a copper vessel,

*b*, in which water is heated, and a cooler, *c*, filled with cold water. The tube *a* is either fused at the bottom or closed by a cork, and is also filled with cold water. Above is a small pan, *d*, of glazed porcelain, with a handle attached, and having a hole, 5 to 6 mm. in diameter, in the bottom. In this pan the phosphorus is fused by means of the hot-water bath, *b*, and falls through the hole in drops, which are solidified before they reach the bottom of the tube *a*.

—C. A. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Hydrometer Scales.* G. Rauter. Zeits. angew. Chem. 1897, 215–217.

It is shown that the degrees of the Baume hydrometer are not of equal value. The formula for the so-called rational Baume hydrometer is  $d = \frac{144.3}{144.3 - n}$  where *d* denotes the specific gravity and *n* the degree Baume. These values plotted out in rectangular co-ordinates, where  $x = d$  and  $y = n$ , give a hyperbola, the asymptotes of which are the *y* axis, and the line  $y = 144.3$ , parallel to the *x* axis.

If  $y = n = 0$ ,  $x = d = 1.000$

1	1.007; difference 0.007
65	1.819
66	1.812; difference 0.023.

Thus from 0° to 66° the value of a degree varies from 0.007 to 0.023 sp. gr. The variation diminishes slowly to 100°, but increases enormously on passing to 144°.

In addition to this inherent disadvantage, confusion has been introduced by the different bases used by various authors. The Dutch system gives  $d = \frac{144}{144 - n}$  where 1.842 sp. gr. corresponds to 65°·8 B. The American,  $d = \frac{145}{145 - n}$  where 1.842 sp. gr. is equal to 66°·3 B. Gerlach's is  $d = \frac{146.78}{146.78 - n}$  where 1.842 sp. gr. is 67°·1 B., and others. This hydrometer is therefore not to be recommended for general use.

The Twaddell hydrometer has degrees of equal magnitude, each equal 0.005 sp. gr.

The densimeter of Fleischer is still simpler. Each degree represents 0.010 sp. gr.

The degrees Baume from 0° to -55°·7 run very closely with degrees Twaddell; degrees Baume from 0 to about 60° do not deviate much from densimeter degrees.

—L. J. de W.

**New Fractional Distilling Apparatus, for Laboratory and Industrial Uses.** A. Tixier, Chénal-Ferron-Donillet and Co. Bull. Soc. Chim. 1897, 17, 392—395.

The apparatus consists of alternate analysers and condensers. The figure shows one analyser A and condenser B. The former is a vertical reservoir *a* traversed by a bulb

tube A connected to the flask; the upper end of the reservoir is furnished with a side tube carrying the thermometer *b* and connected to the condenser. The upper end of the bulb tube A communicates with the side condenser B, which leads into the lower part of the analyser. The siphon S connects the flask with the analyser. The three-way cock with side tube *t* on the siphon enables the action

of the siphon to be started when it does not take place spontaneously, and permits of the regulation of its flow. The cock *r* serves to empty the apparatus and for the taking of samples during the progress of the operation.

The flow of water through B, the flow of the siphon, and the rate of boiling may all be separately regulated. When condensation is complete in B, the liquid in the reservoir distils by the heat of the vapours in the bulb tube A; if condensation is not complete in B, the vapours will bubble through the liquid in *a* and analyse it.

The thermometer in the central tube A rises steadily, but that in the side tube passes rapidly from one boiling point to the other.

Several examples of the results achieved by this apparatus are given; one is quoted. A mixture of 1 litre of alcohol of 89.2° and 1 litre of wood spirit for denaturing, containing 250 c.c. of acetone, gave the following fractions:—

C.	Ce.
54—59 .....	215 acetone.
59—65 .....	15
65—69 .....	145 methyl alcohol.
69—79 .....	115

whilst in the flask 830 c.c. of alcohol boiling at 80° were left. Diluted with 50 per cent. of water, the separation would have been more complete. The technical apparatus contains several analysers and condensers; it is fully described in the patent specification.—A. C. W.

**Aluminium, The use of, for Condensers.** T. H. Norton. J. Amer. Chem. Soc. 1897, 19, 153—156.

In his experiments, the author used a condenser so constructed that the condensing vapours did not come into contact with any substance other than aluminium. When organic liquids, such as ethyl alcohol, benzene, nitrobenzene, chloroform, ethyl ether, and acetone were distilled, the residues in the distillate showed that the aluminium was practically not attacked. The results obtained from the distillation of water, demonstrate that as far as the purity of the product is concerned, aluminium possesses about the same advantages over glass as tin, but in lightness and conductivity, it exhibits marked superiority to the latter metal. The high thermal conductivity, and the absence of brittleness in aluminium, are factors in its favour as compared with glass, for distillation purposes.—J. L. B.

**Gas-Tap, Automatic.** H. Michaelis. Ber. 30, 282—284.

To obviate the inconvenience and risk liable to occur when working with constant-level water-baths or with Liebig condensers, through failure of the water supply, the author has devised the following gas-tap, which closes automatically when the water current, through any cause, ceases.

The apparatus is connected with both the gas and water supply, and its construction is shown in the accompanying figure.

The gas flows through the tubes *h*, *i* so long as the lever attached to the tap B remains horizontal. This lever carries at one end a weight A and at the other a funnel C. The tube E is connected with the water-supply, the tap being at *g*, and through it water flows into the funnel C, running away partly through a small opening at the apex

of the funnel and partly through an overflow opening somewhat below the funnel rim, into the larger funnel D. So long as the funnel C is filled with water—*i.e.*, so long as the water-feed continues—it balances the equal weight A, and the tap remains open. Should the water-supply cease, the water in C runs gradually away through the small apical opening, and the weight A then bears the lever down until it takes up the position shown by the dotted lines, in which the tap is closed.

The water-supply to the funnel C may be the overflow from the water-bath or condenser. The water must, naturally, be fed into C more quickly than the lower opening in the funnel will allow it to flow into D.

There is also a small hook, not shown in the figure, to hold the lever horizontal, should it be desired to use the burner alone and without the water-supply.—J. T. C.

*Chlorine, A Carbon Tetrachloride Solution of.* G. Darzens. *Comptes Rend.* 1897, 124, 563.

THE author remarks on the great advantages resulting from the use of a carbon tetrachloride solution of chlorine for laboratory purposes, and its superiority over other chlorinating agents. A 10 per cent. solution of chlorine may be kept almost indefinitely in a well-stoppered bottle.

—H. T. P.

*Reagents free from Arsenic, Preparation of.* J. Habermann. *Zeits. angew. Chem.* 1897, 201—202.

HYDROCHLORIC acid and ammonia sold as pure almost always contain traces of arsenic. When arsenic is contained in ferrous sulphide used for generating sulphuretted hydrogen, it not only passes over with this gas, but accumulates in ammonium sulphide made from the latter. Some years ago the author proposed (*Verhandl. d. naturf. Vereins in Bräun.* 17, 11) the use of calcium sulphide, magnesium chloride, and water for the preparation of sulphuretted hydrogen free from arsenic. Sulphuretted hydrogen can be easily freed from arsenic by the method of O. Jakobson (*Ber.* 20, 1999). The sulphuretted hydrogen, deprived of the greater part of its moisture, is passed over a small quantity of iodine and then washed by distilled water.

To remove arsenic from so-called "pure" hydrochloric acid of commerce, a small quantity of potassium chlorate is added (less than 0.5 gm. per litre) and the liquid distilled from a glass retort, the neck of which is connected by a Liebig's condenser to a receiver containing so much distilled water that when two-thirds to three-quarters of the contents of the retort have passed over, the liquid in the receiver contains 20 to 25 per cent. of hydrochloric acid. The distillate, of course, contains chlorine, but this is no disadvantage in acid used to destroy organic matter in testing for arsenic. If it be desired to obtain acid containing no free chlorine, the first portion of the distillate is collected separately and the receiver changed as soon as the liquid distills over absolutely colourless. In any case, the whole of the arsenic remains in the residue in the retort.

The traces of arsenic contained in commercial ammonia may be removed by adding a few c.c. of a not too dilute solution of potassium permanganate and distilling from a glass retort into a receiver containing a quantity of distilled water equal to two-thirds of the volume of the ammonia used. It is advisable to interpose between the retort and receiver a small vessel containing water for washing, arranged so as to prevent regurgitation. Ammonium sulphide may then be made from this purified ammonia and purified sulphuretted hydrogen so as to be absolutely free from arsenic.

—L. J. de W.

*Gas-Analysis Apparatus.* O. Bleier. *Ber.* 30, 697—701. (See also this Journal, 1896, 294, 615, 672.)

THE jacketed burette A (Fig. 1) contains 100 c.c. between the upper and lower taps  $h^2$  and  $h^1$ . This space is divided in  $\frac{1}{2}$  c.c., with the exception of the upper 30 c.c., where the tube widens. If volumes smaller than 30 c.c. have to be measured, a graduated levelling-tube, Fig. 3, is used. The upper tap  $h^2$ , shown in detail in Fig. 2 (*a* and *b* are alternative forms), puts the measuring tube in communication with any one of four capillary tubes, to three of which gas

pipettes I., II., and III. are attached; the fourth capillary serves for the admission of the sample and for the attachment of additional pipettes.

Fig. 1

Fig. 2.

Fig. 3

After ascertaining that each capillary is filled up to the tap  $h^2$  by the absorbing liquid from the pipette, the burette is put into communication with the capillary *a*, and the reservoir is then raised until burette and capillary are filled with water. The gas is now allowed to enter at *a*, the water in the burette flowing out at *b*. Analysis follows in the ordinary way, by putting the burette in communication with each pipette in turn.

The tap  $h^2$  may have as many as 6—8 communicating tubes; and, if necessary, two or more pipettes may be placed in series, as in the Orsat apparatus.

The ordinary apparatus used for subjecting gaseous mixtures to the action of the electric spark or of electrically-heated wires may be advantageously replaced by the explosion tubes *a*, *b*, and *c*, Fig. 4. These are capillary tubes carrying a bulb, through which wires are fused, or into which wires are carried through a rubber stopper, as in *c*. The method of using these tubes is as follows:—The tube employed is connected to a pipette and filled with water; the open end is then connected to the vessel (or burette) containing the gas, and the electric circuit closed, the current passing through the water. Now the gas is allowed

to enter. The explosion is not transmitted by the wet capillaries, and in this way any quantity of an explosive mixture may be safely burnt by one passage from pipette

Fig. 4

to burette. If, however, the explosive mixture contain other gases, the passage through the capillary must be several times repeated. The tube *c* is specially adapted to the combustion of methane and other hydrocarbons; in combination with the author's apparatus for gas titration (this Journal, 1896, 672), more accurate results are obtained than with the burette.

The tube *b* is suitable for direct nitrogen determinations. The mixture, with oxygen in the proper proportions, must be led backwards and forwards between the burette and a pipette filled with dilute alkali. The rapidity of absorption is less than was observed by Rayleigh and Ramsay with a spark of equal length. More rapid absorption is obtained by the use of several capillaries in series.—A. C. W.

#### PATENTS.

*Thermometer, An Improved.* A. Luraschi, 15, Cross Street, Hatton Garden, London. Eng. Pat. 8547, April 23, 1896.

THE thermometer has within its bulb (an outer bulb) a spiral tube, which forms an upward continuation of the fluid index column of the thermometer, the lower end of the spiral being connected with the bore of the thermometer stem, of which it is the continuation. The spiral continues upwards to the highest part of the interior of the bulb, and there it terminates, remaining open to the interior space there. The bulb and the upper part of the spiral are filled with a suitable fluid, and a small quantity of mercury is introduced into the stem and the lower part of the spiral.

—R. A.

*Butter, Margarine, and the like, and in the Method of Employing such Apparatus; Impts. in and relating to Apparatus for Testing.* R. Wells, Scarborough. Eng. Pat. 10,627, May 18, 1896.

THE method depends upon the difference of time in the solidification of butter and margarine, after they have been melted by a gentle heat. The melted fat is poured upon the surface of water contained in a glass cylinder, the temperature of the water being 45°–55° F. If the article tested be pure butter, it is stated that solidification will ensue in from 15 to 20 minutes. If adulterated with margarine, a longer time will be required, and, in accordance with a table given, the proportion of admixed margarine may be read off.—W. P. S.

#### INORGANIC CHEMISTRY.—QUALITATIVE.

*Drinking Water, Analysis of.* G. Romijn. Nederl. Tijdschr. v. Pharm. Chem. en Toxicol. 1897, 87–98.

In order to lessen the time required for an analysis, and also to prevent disagreement between analysts, the author proposes a scheme which does not require a quantitative process, but which still gives sufficient data as to the com-

position of the sample. For example, if the water in a certain locality never contain more than 0.03 gram of chlorine per litre, it is best tested by taking 200 c.c. of the sample, adding a little potassium chromate, and then 5 c.c. of a solution of silver nitrate containing 5.75 grams of that salt per litre. If now the precipitate remain white, there is at once the proof of an abnormal excess of chlorine. In a similar manner excessive quantities of lime, sulphates, &c., may be proved by adding to a measured quantity of the sample, a solution of ammonium oxalate in dilute acetic acid, or a solution of barium chloride of known strength. After filtering there should be no further turbidity produced by these reagents. As regards ammonia, the author clarifies the water by means of sodium carbonate and then adds Nessler solution, and nitrites are tested for with meta-diamidobenzene in presence of sulphuric acid; their very presence should condemn the sample. Organic matter is determined by means of permanganate solution; any sudden excess required, must be looked upon as suspicious. Metals should be entirely absent.—L. de K.

#### INORGANIC CHEMISTRY.— QUANTITATIVE.

*Liquid Ammonia, Analysis of Commercial.* A. Lange and J. Hertz. Zeits. angew. Chem. 1897, 224–228.

ALTHOUGH liquefied ammonia has been used in the refrigerating industry for some years, and has been prepared on the large scale in Germany, nothing has hitherto been published on the subject with the exception of the work of Strombeck on American ammonia (this Journal, 1892, 736), and a recent method of analysis by Bunte and Eitner (J. für Gasbel., March 13, 1897). The authors have examined the impurities of a number of German products without attempting a quantitative separation.

If a large quantity of commercial ammonia, say 40 lb., be allowed to evaporate spontaneously, a residue is left of a yellow or dark-brown colour which, besides mineral impurities (oxide of iron), often contains a small quantity of machine-oil floating on the surface, and removable in a separating funnel. Ammonium carbonate is almost always present, often crystallised in fine needles. The residue also naturally contains more or less  $\text{NH}_3$  in solution. By treatment with dry potassium carbonate the liquid was freed from the water, and the greater part of the ammonia driven off, the remainder being removed by heating under a vertical condenser. The remaining liquid was purified from the brown colouring matter by a single distillation. It distilled between 70° and 150° C. This was separated into fractions boiling at 70° to 90° and 116° to 130° C. The intermediate portion was a mixture of the two. The higher fraction consisted principally of pyridine and its higher homologues; that boiling above 140° smelt strongly of nicotine. Occasionally from the residue of the distillation which contains machine-oil, scales separate out which were recognised as naphthalene by the melting point, 80° C.

The fraction boiling from 70° to 90° C. had a distinct smell of pyridine, which could not be removed by repeated distillation. When much pyridine is present, it may be estimated by titration with  $\frac{1}{2}\text{N} \cdot \text{H}_2\text{SO}_4$ , and methyl orange as indicator. The quantity of concentrated sulphuric acid calculated from the titration is added to the strongly cooled liquid, and the lighter layer separated from the heavier layer of sulphate, the separation being precise. When only a small quantity of pyridine is present, or to remove the last traces, the liquid is agitated with freshly-fused zinc chloride, filtered and rectified. It boils at 74 to 77° C., and therefore appears to be simple. It is decomposed by boiling alkali into ammonia and acetic acid, but contains only 23.9 to 24.1 per cent. of nitrogen, while acetonitrile, which the above reaction indicates, contains 34.1 per cent. of nitrogen. It must, therefore, notwithstanding its constant boiling-point, be a mixture. In coal-tar, acetonitrile is always associated with ethyl alcohol, from which it cannot be separated by fractional distillation. From the work of Vincent and Delachanel (Bull. Soc. Chem. 1880, 33, 405), the mixture must consist of 70 per cent. of acetonitrile and 30 per cent. of alcohol. Both constituents were further

chemically identified. In the light boiling fraction, benzene was found. Other alcohols, acetone, and ammonium salts found by Strombeck could not be detected.

For the valuation of liquefied ammonia, it is usually sufficient to determine the residue after volatilisation, without attending to its composition. For this purpose the bottle is placed horizontally, and an open steel tube screwed on the valve. By opening the valve, 20 to 50 grms. are allowed to flow into an Erlenmeyer flask. The previously-tared flask is quickly weighed with the ammonia and the stopper. The stopper has two perforations for a potash tube and a glass tube bent at right angles, the latter being closed and the former open, so that the volatilised ammonia must pass through the potash tube. At the ordinary temperature, two to three hours suffice for the dissipation of the ammonia; occasional shaking assists the operation. The residue, which contains more or less ammonia, according to its composition, is heated not above 40° C., and then dry air is passed in by the glass tube. Both tubes are then closed, and the apparatus is again weighed, giving data for the residue.

By testing a number of samples from the same bottle under various conditions, it was shown that the contents were homogeneous, with no tendency to settle out. Samples, each of 33 grms., drawn from one and the same bottle, in  $\frac{1}{2}$ , 1, and in five minutes, gave 0.9, 0.9, and 1.0 per cent. residue. The whole contents of the bottle, 19.5 kilos., were allowed to evaporate in 36 hours, and a residue was obtained of 185 c.c., with a sp. gr. 0.87, corresponding to 0.84 per cent. Under the inverted condenser this lost only 3 per cent. of  $\text{NH}_3$ , which does not alter the result. Experiments were also made to show that the volatilised ammonia does not carry off any of the impurities. Linde's Ice Machine Co. were perhaps the first to attempt a volumetric determination. In this method, however, no account is taken of the difference in specific gravity of the ammonia and the residue. The authors independently arranged a similar apparatus, taking account of specific gravity. They determined that liquid ammonia, at the usual temperature of  $-38^\circ\text{C}$ ., has a specific gravity of about 0.68. That of the residue, varies with its composition, but 0.9 is a sufficiently exact average.

The essential part of the apparatus is a glass tube of 30 to 40 mm. internal diameter, at the lower end of which a narrow glass tube is fused, of 5 mm. bore, and holding 1.1 c.c. The whole tube holds about 100 c.c., with a mark at 19 c.c. representing 33.3 grms. of ammonia. The lower narrow portion is divided into 15 parts, so that each division represents 0.2 per cent. When filled to the mark with ammonia, a grooved cork is inserted, and the contents are allowed to evaporate spontaneously. The operation is complete in 3 hours, or if hastened by placing the lower tube in water, in  $\frac{1}{2}$  hour. The process is at fault if the ammonia contain much water, as then the residue may contain 25 per cent. of ammonia; otherwise the error from dissolved ammonia is so slight as to be negligible.

The authors state that small quantities of gas are dissolved in liquid ammonia, which escape with that gas on evaporation, and are not found dissolved in the residue. They are engaged in the investigation of these gases.

—L. J. de W.

*Sodium Bicarbonate, Analysis of.* G. Lunge. *Zeits. f. angew. Chem.* 1897, 169—171.

PROF. LUNGE gives the details of a process devised by K. J. Sundstrom for the rapid analysis of sodium bicarbonate, which has been in use for some years past at the ammonia-soda works at Trenton (Michigan, U.S.A.). It has the advantage over Lunge's method in not requiring semi-normal ammonia, and although not so accurate as the gas volumetric method, is sufficiently so for all practical and commercial purposes. It is based upon the fact that a sodium bicarbonate solution, when treated with caustic soda lye, decomposes according to the following equation—

When the whole of the bicarbonate has been converted into normal carbonate, the addition of a single drop of caustic soda lye has the effect of causing the mixture to give a

brown coloration with silver nitrate solution; and this point is determined by spotting on a porcelain plate. The total alkali is determined by titration with N-acid, and the two estimations give all the data necessary for the calculation. The caustic soda lye is prepared by making up a solution of  $20^\circ\text{B}$ . from commercially pure caustic soda, precipitating with barium chloride, saturating with barium hydrate, and diluting to N-strength. The titration value is determined with N-hydrochloric acid in the cold, using phenolphthalein as an indicator. In a given sample, two lots of 4.2 grms. were weighed off; the total alkali in one being determined with N-hydrochloric acid. The other portion was placed in a 250 c.c. porcelain dish (Lunge prefers to use a glass beaker), and covered without stirring with 100 c.c. of water at a temperature of  $15^\circ$ — $20^\circ\text{C}$ . Approximately the amount of the N-caustic soda solution was then run in. In this case, knowing that the bicarbonate was at least 96 per cent., 48 c.c. were used, and the mixture was stirred until the whole was dissolved, which required about one minute. The addition of the N-NaOH was then proceeded with, adding first 0.5 c.c., subsequently 0.2 c.c., and finally drop by drop. After each addition, a drop of the solution is spotted with silver nitrate solution (20—25 per cent.) on a porcelain plate, until a brown coloration is formed at once. The percentage of bicarbonate is obtained by multiplying the N-NaOH used by 2; that of the normal carbonate by subtracting the N-alkali from the N-acid, and multiplying the difference by 53.42nds.

Thus, 4.2 grms. of bicarbonate require—

	C.c.
N-acid .....	49.7
N-alkali .....	49.7
	<hr/> 0.2

Therefore—

$\text{NaHCO}_3 = 2.0 \times 49.7$ .....	= 99.4
$\text{Na}_2\text{CO}_3 = 0.2 \times 53.42\text{nds}$ .....	= 0.25
$\text{NaCl}$ .....	= 0.0
Difference .....	= 0.35
	<hr/> 100.0

An attempt to use ordinary N-NaOH in place of that recommended by Sundstrom was, according to Lunge, not attended with good results, and, moreover, since the solution contains caustic laryta, a turbidity in it at once demonstrates the presence of carbonate. It is therefore advisable in all cases to allow the liquor to settle, to estimate its value with N-acid, and any indicator, before each series of determinations, and to use it from a burette which can be filled from the lower end, the upper end communicating with the stock bottle, which is provided with a soda-lime filter for the entering air.—T. A. L.

*Thoria, Behaviour of, with Oxalic Acid and Ammonium Oxalate, and the Estimation of.* C. Glaser. *Zeits. Anal. Chem.* 36, 213—219.

IN a previous paper upon the analysis of monazite sand (*Chem. Zeit.* 1896, 63, 612; this Journal, 1896, 675—677), the author stated that he had found that when thoria had been kept in solution as oxalate by ammonium acetate and afterwards was re-precipitated by ammonia and redissolved in mineral acid, it was then no longer possible to effect its complete precipitation as thorium oxalate by saturating the nearly neutralised and boiling solution with ammonium oxalate, and allowing the liquid to cool. He has since investigated this behaviour, and he finds that the reason of the incomplete precipitation is because, in nearly neutral solutions, thorium oxalate is somewhat soluble in ammonium oxalate—a fact which was not known at the time of his former paper, but which has since been established by other workers. The facts that he has elucidated are as follows:—From a boiling nearly neutral mineral acid solution, thoria is not precipitated at all by ammonium oxalate, even when no excess of the latter is present; thorium oxalate is only precipitated on allowing the solution to cool, when it settles down in a crystalline form. If, however, a large excess of ammonium oxalate be present it may be entirely prevented from precipitating even in the cold. Ammonium acetate

merely increases the soluble action of the liquid, but, contrary to what the author has surmised, it has no other influence.

Thoria is quantitatively precipitated as oxalate by oxalic acid, or ammonium oxalate even in excess, and in the presence of ammonium acetate, by rendering the solution strongly acid with hydrochloric acid.

The composition of the oxalate formed varies according to the mode of precipitation. If the thoria be dissolved in hydrochloric acid and the solution boiled before oxalic acid is added, a precipitate of thorium oxide and oxalate forms on adding the oxalic acid; sometimes also the oxide is partially precipitated before the oxalic acid is added, and remains insoluble on addition of more hydrochloric acid. On the other hand, if the oxalic acid be added before the solution is boiled, the normal oxalate precipitates on cooling, having the composition  $\text{Th}(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$  (dried at  $100^\circ \text{C}.$ ).

The oxalate, which is precipitated by ammonium oxalate (not in excess) from nearly neutral solutions by boiling and then allowing to cool, is also not of normal composition. Neither is the oxalate precipitated by ammonium oxalate in the presence of excess of hydrochloric acid. In the latter case it was found that the oxalate formed corresponded to the formula  $\text{Th}(\text{C}_2\text{H}_3\text{O}_6)_2 \cdot 2\text{H}_2\text{O}$  (dried at  $100^\circ \text{C}.$ ).

The fact of the solubility of thorium oxalate in ammonium oxalate, raises the question whether in the scheme of analysis of monazite sand given in the author's earlier paper (*loc. cit.*), some of the thoria would be held in solution by the excess of ammonium oxalate used and so be included among the zirconia earths forming soluble oxalates. It is evident that in separating thoria from zirconia, more ammonium oxalate should be avoided than what is necessary to keep the zirconium oxalate in solution, and this can easily be done when only these two earths are present in the solution. When cerium is also present, it is not so easy to avoid an excess of ammonium oxalate, owing to the formation of the insoluble cerium oxalate.

The action of a large excess of ammonium oxalate on thoria in the presence of ceria was therefore next investigated, and it was found that, even in the presence of a very large excess of ammonium oxalate (about 5 grms.), about half the thoria was precipitated as oxalate along with the cerium oxalate, the precipitation being effected by adding the ammonium oxalate to a boiling, nearly neutralised solution of the earths in sulphuric acid, and then allowing the liquid to cool. The remainder of the thorium was kept in solution by the excess of ammonium oxalate used, and was precipitated from the filtrate from the oxalate precipitates, by the addition of hydrochloric acid. About one-half the thorium was precipitated with the cerium, both when relatively much or little cerium was present.

It was further found that in separating the oxalates of thorium and cerium by ammonium acetate, it was important to avoid a large excess of the acetate, as it was found that cerium oxalate is slightly soluble in this reagent. If an excess of ammonium oxalate be used, it only requires the addition of a few c.c. of ammonium acetate solution to dissolve out the whole of the thorium from the cerium oxalate.

In order to see whether thorium was kept in solution by the excess of ammonium oxalate and included therefore among the zirconia earths when making an analysis of monazite sand by the author's published scheme, a sample of monazite sand was analysed by this method, but after separating the cerium earths and the thoria as insoluble oxalates, the filtrate, containing the zirconia earths, &c., was treated with excess of ammonia, the precipitated bases filtered off, and redissolved in an excess of hydrochloric acid, oxalic acid added, and the liquid allowed to stand for some hours in a warm place. No precipitate of thoria was formed. The zirconia finally separated from the sample, was likewise examined in the same way, and found to be free from thorium.

The fact that thoria, although known to be soluble in excess of ammonium oxalate, had been completely separated, together with the cerium earths, causes the author to suggest the possible presence of some earth among the cerium earths which by a catalytic action brings about the complete precipitation of the thoria. Indeed, cerium itself has this

effect in some degree. But as the conditions are not yet understood, in order to insure the determination of all the thoria, he recommends the treatment of the filtrate from the precipitates of thorium and cerium oxalate, and the subsequent examination of the zirconia, as above described.

If cerium has not to be determined, then the solution of the earths in sulphuric acid, after nearly neutralising, may be at once treated with excess of hydrochloric acid and oxalic acid, which will precipitate all the thoria and most of the ceria as oxalates, the zirconia and other earths passing into solution. The thoria and ceria can then be separated by ammonium acetate as usual. He found, however, that the thoria precipitated in this way was impure in colour, and he does not recommend this modification.

The following corrections and amplifications should be made in the table of the characteristic reactions of the rare earths given in his former communication:—

1. The statement that thoria and cerium protoxide are precipitated by ammonium carbonate in the same way as by ammonia is incorrect. In Graham-Otto it is said "thoria and cerium protoxide are easily soluble in an excess of ammonium carbonate, as are also the majority of the earths mentioned, and are precipitated from the solution on boiling."

2. The behaviour of thoria with ammonium oxalate should be stated: precipitates in the cold, soluble on heating, crystalline on cooling, provided a large excess of the reagent be avoided. Excess of hydrochloric acid precipitates the oxalate completely on cooling.

3. The statement that thorium oxalate, which is held in solution by ammonium acetate and ammonium oxalate, is in part precipitated by hydrochloric acid, must be enlarged by the addition that a sufficiently large excess of hydrochloric acid causes a quantitative precipitation.

4. It must be noted that zirconium oxalate is soluble in hydrochloric acid.

5. Cerium oxalate is slightly soluble in ammonium acetate.—H. S. P.

*Silicon, A Rapid Method for the Determination of, in Silico-Spiegel and Ferro-Silicon.* C. B. Murray and G. P. Maury. J. Amer. Chem. Soc. 1897, 19, 138—139.

THE authors describe the following method for the determination of silicon in a rapid and accurate manner:—0.5 gm. of the very finely divided sample is placed in a porcelain or platinum dish; 50 c.c. of water, 40 c.c. of hydrochloric acid (sp. gr. 1.20), and 12 c.c. of sulphuric acid (1 part of sulphuric acid (1.84 sp. gr.) to 3 parts of water) are poured on it, and the contents of the dish heated until copious fumes of sulphuric acid are given off. When cool, 10 c.c. of hydrochloric acid are added, and the whole is heated to soften the sulphate of iron; finally it is treated with 75 c.c. of water, and raised to boiling. The heating is discontinued, and note taken as to whether there is any effervescence when boiling ceases. Should this occur, the liquid must be evaporated until copious fumes of sulphuric acid are again given off, and then it is treated in the manner above described. The solution is filtered, washed with hydrochloric acid and hot water, ignited in a platinum crucible, and weighed. A few drops of sulphuric acid and enough hydrofluoric acid are added to dissolve the silica. The liquid is then evaporated to dryness, heated to decompose the sulphates, cooled, and weighed. The difference in the two weights represents silica. The whole operation can be accomplished in 30 minutes.—J. L. B.

*Pig Iron, Determination of Sulphur in.* A. A. Blair. J. Amer. Chem. Soc. 1897, 19, 114—115.

ATTENTION has frequently been drawn to the fact that the residue left from pig iron after treatment with dilute hydrochloric acid, contains sulphur. The author is able to convert all volatile sulphur compounds into hydrogen sulphide by passing the evolved gases through a tube filled with pumice, heated to redness. This method is not, however, of general application. It is pointed out that sulphur is liberated from pig irons under the following conditions:—1. As hydrogen sulphide, by solution of iron in hydrochloric acid. 2. As other compounds, not absorbed by alkaline lead salts, or oxidised by bromine or potassium

permanganate. 3. In some form upon which boiling hydrochloric acid has no action, but which is oxidised by nitric acid or aqua regia. 4. In some form not attacked by nitric acid, hydrochloric acid, or aqua regia. When sulphur exists in the last-mentioned state, it may conveniently be estimated by Bamber's method (this Journal, 1894, 665).—J. L. B.

*Nickel, Estimation of, in Nickel Steels.* J. Spüller. Chem. Zeit. 1897, 21, 243–244.

THE following colorimetric method is stated by the author to give satisfactory and rapid results. 2 grms. of the sample to be examined, and 2 grms. of a normal nickel steel containing a known amount of nickel, are weighed out into two 250-c.c. flasks, and about 60 c.c. of nitric acid (sp. gr. 1.2) added to each. The contents of the flasks are boiled until solution is complete, and nitrous fumes are no longer given off. When cold, the iron is precipitated with zinc oxide, and the green colours of the resulting filtrates are compared, a white homogeneous paper being used for a background. Since nickel steels generally contain from 1 to 7 per cent. of nickel, a fairly reliable result can be quickly arrived at, if the standard has about the same percentage of nickel as the sample. The author employs three standard nickel steels containing 1, 3, and 5 per cent. of nickel.

More accurate results may be obtained by comparing the colours in a calibrated vessel and adding a known volume of water to the test until the colour is identical with the standard. Steels containing under 1 per cent. of nickel cannot be submitted to this method, on account of the faint colour of the solution.—J. L. B.

*Antimony, Estimation of, as Tetroxide.* H. Baubigny. Comptes Rend. 1897, 124, 499–502. (See also page 475, col. 1.)

THE estimation of antimony as tetroxide was first proposed by Bousen in 1858, but subsequent investigations by Bansen himself and by Brunck and Read have thrown some doubt on the stability of  $\text{Sb}_2\text{O}_4$  at high temperatures. Starting with the pentoxide  $\text{Sb}_2\text{O}_5$ , the author has ignited it in crucibles, from which the gases from the flame were carefully excluded at temperatures gradually increasing up to  $800^\circ$ , at which temperature its weight became constant. The analysis of the substance thus produced was found to correspond exactly to the composition required by the tetroxide  $\text{Sb}_2\text{O}_4$ .—J. S.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*Schiff's Reaction applied to Acid Magenta.* L. Lefèvre. Bull. Soc. Ind. Mulhouse, 1897, 84–86.

ACCORDING to Cazeneuve (Bull. Soc. Chim. 1896, 723; cf. this Journal, 1896, 560), Acid Magenta does not give Schiff's reaction. This, as the author points out, is erroneous, and he refers to Schiff's original paper (Comptes Rend. 1865, 45), pointing out at the same time that the difference observed by Cazeneuve is due to a time effect. The particular aldehyde employed also influences the test. Thus a solution of Acid Magenta (1:1,000) acidified with a drop of sulphuric acid and decolorised with bisulphite regains its colour when treated with a few drops of a 10 per cent. formaldehyde solution, whilst a much larger quantity of acetaldehyde is required to effect the same result. In all cases, however, the colour returns much more rapidly with Magenta than with Acid Magenta. Urbain (Bull. Soc. Chim. 1896, 155; this Journal, 1896, 560) states that condensation products are formed by the action

of aldehydes on rosanilines, and Cazeneuve suggests (*loc. cit.*) that if this be the case the condensation takes place in the ring in Magenta at the position occupied by the sulphonic acid group in Acid Magenta, since the latter does not react with aldehydes. In Schiff's original memoir, however, it is pointed out that the regeneration of the colour of the decolorised Magenta solution is due to the formation of a new compound. The following is the quotation referred to:—On shaking a dilute sulphurous solution of the sulphate, or of any other salt of Rosaniline, with a few drops of aldehyde, sulphurous acid is given off; the solution turns red, then violet, and a precipitate is gradually formed consisting of small violet scales with a bronze-like lustre.—T. A. L.

*Linseed Oil, Differences between Boiled and Raw.* G. Morpurgo. Giorn. di Farm. di Trieste, 1896, 1, 361; Chem. Zeit. 21, 37.

THE presence of lead, zinc, or manganese in linseed oil shows that the oil has been boiled. The absence of these metals does not, however, prove the oil to be raw oil, as some so-called boiled oils (prepared by an aëration process) are quite free from metallic oxides. The author has found the following method a reliable one for distinguishing boiled from raw linseed oil. The oil is saponified, the soap dissolved in water, and the resulting clear solution treated with common salt until no more soap separates out. If, after filtration, the filtrate be made strongly acid with acetic acid, a turbidity shows that the oil used was boiled, whilst the filtrate from a raw oil remains clear.—W. P. S.

*Alkaloids, Action of Tannin on Some.* O. de Coninck. Comptes Rend. 1897, 124, 506–508.

THE author describes some experiments on the action of tannin on alkaloids, and has arrived at the following method of distinguishing pyridine from piperidine. On adding a few drops of tannin solution (1.434 gm. in 20 c.c.) to solutions of a few drops of the two bases in 150 c.c. of water, a white amorphous precipitate is formed in the case of pyridine, whilst with piperidine a clear yellow liquid is obtained, which becomes gradually darker, and finally reddish-brown.—J. S.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Free Nitrogen in Purified Coal-Gas, Determination of the.* G. Arth. Bull. Soc. Chim. 1897, 17, 427–432.

THE determination of nitrogen in coal-gas by measurement of the residue after an eudiometric combustion is inaccurate, for the operation is only carried out with a small volume of gas, generally poor in free nitrogen, and the volume of the residue is influenced by the different impurities introduced in the previous operations.

In the purified gas, cyanides are present in such small quantity that it is generally impossible to show their presence in several litres; basic nitrogen compounds can be removed by sulphuric acid; thus Dumas' method may be employed.

In the figure, A is the measuring vessel, each of the bulbs containing 500 c.c.; the cork in the upper end carries the water manometer C and the tube k. To avoid the error due to measuring over water, when not in use, A is kept partly full of gas under a slight pressure. a is a three-way cock, the lower tube of which has two branches d and e. F is a small wash bottle containing strong sulphuric acid. G is a combustion tube, placed in a furnace, containing a layer of copper oxide 55 cm. long, and a coil of bright copper 15 cm. long. H is a nitrogen-measuring apparatus, such as is used in organic combustions. The end of G near this apparatus should be bent,

as shown, to prevent fracture of the tube by the water formed in the combustion. E is a tube, 25 cm. long, containing manganese carbonate dried at 100° in an

atmosphere of carbon dioxide; this tube is also placed in a furnace; it communicates with the three-way tap *b*, the lower limb of which dips into mercury. From *a* to *i* the tubes have a bore of about 2 mm.; *c* and *i* should be as near together as possible.

The copper oxide end of *G* is heated, the copper being withdrawn, if the tube has been used before oxygen is sent through; *c* is connected with the gas supply, the tube *u* filled with gas, and the clip *e* closed. (*F* and *G* are not yet connected.) When *G* is sufficiently hot, *E* is heated, and, after carbon dioxide has bubbled through *F* for a short time, *G* is connected. In about 10 minutes the copper coil is introduced, the gas lighted under it, and *H* connected up.

The measuring vessel is now filled; the gas enters at *f*, is allowed to fill the upper bulb, the clip on *f* is closed, and *B* is lowered until the air from the manometer tube enters *A*. *B* is raised and lowered several times to effect complete replacement of the air in the manometer; the gas is then expelled through *d*, and the whole process repeated. The whole of *A* is now filled with gas, and the water standing at the zero mark, *D* is closed, the pressure and the temperature read off. The air being driven out of *G*, the current of gas from *E* is diminished and allowed to pass out through *m*. The gas is then sent slowly through the combustion tube at a rate of about three bubbles per second (75 minutes will be required for 1 litre); the level of *B* is kept adjusted so that there is always a pressure of 4–5 cm. on the gas. If sufficient nitrogen collects in the burette, only 500 c.c. may be burnt, but if the volume be small, the whole litre should be used. When the liquid in *A* reaches the mark, *D* is closed, the gas allowed to flow until the previous pressure is shown on the manometer, then *c* is sharply closed, and the carbon dioxide allowed to sweep the gas out of *F* and *G*. The nitrogen is now measured in the ordinary way. If the barometer and thermometer have varied during the experiment, the volume of gas burnt must be corrected accordingly.

—A. C. W.

*Paraffin, Estimation of, in Distillates of High Boiling Point from Brown Coal Tar and Crude Petroleum.*  
D. Holde. Zeits. angew. Chem. 1897, 116–117.

FOLLOWING the suggestion of Höland to apply his method (this Journal, 1894, 286), to petroleum products, the author found, as Aisnman's experiments showed, that the lubricating oil distillate from crude petroleum was with difficulty soluble in alcohol. 10 to 20 grms. of various Russian oils required 1 to 1.5 litres of alcohol for solution, besides the quantity for washing and reprecipitation. In addition to oil, this large amount of alcohol dissolved considerable quantities of paraffin, 1 litre of absolute alcohol at 0° C. dissolving 0.3 gm. The separated paraffin was with difficulty freed from particles of oil, and was therefore generally in a greasy condition.

The methods of Pawlowski and Fielemowicz and of Zoloziecki (this Journal, *loc. cit.*) were also found to be costly, troublesome, and inexact.

The best results were obtained by working out a proposal of Grotowsky, modified by Engler and Böhm (Dingl. 1886, 262, 473; this Journal, 1887, 371–372), in which an ethereal solution of the oils is precipitated by alcohol in the cold, although, according to Höland, considerable quantities of paraffin remain in solution even at several degrees below 0° C., and the repeated crystallisations recommended by Engler and Böhm must waste much time. The author avoids these faults by using the smallest possible quantity of fluid for solution and precipitation at a very low temperature (–18 to –20° C.), and by working as quickly as possible. The precipitated paraffin is washed at –18 to –20° on a double filter with the smallest possible quantity of a mixture of ether and alcohol. Analyses in duplicate of a number of typical lubricating oil distillates of various fractions gave results differing by only a few tenths per cent., and tests made on artificial mixtures of oil and paraffin gave only slight deviations from the known paraffin content. The operation requires only from 1 to 2 hours. Further details are to be found in the Mitt. aus den Kgl. Techn. Versuchsanstalten, 1886, Heft 4, 473.—L. J. de W.

*Raw Fibres [Vegetable], A New Method for the Quantitative Estimation of.* Leblin. Arch. Hyg. 1897, 28, 212.

THE method depends upon the use of ammoniacal hydrogen peroxide, by means of which starch and most of the vegetable albuminoid substances, especially the characteristic glutins, are dissolved, whilst pure cellulose is barely attacked. The following mode of procedure, which may be modified according to circumstances, is given:—3 to 5 grms. of the meal or bran, powdered so as to entirely pass through a sieve of 0.2 mm. mesh, are well stirred into 100 c.c. of water, contained in a roomy beaker, so that no lumps remain, and the whole is boiled for half an hour. 50 c.c. of 20 per cent. hydrogen peroxide are then added, and the boiling continued for 20 minutes with gradual addition of 15 c.c. of a 5 per cent. ammonia solution. The boiling is continued for a further 20 minutes after the addition of the ammonia is completed, and the whole is then filtered hot through a weighed filter, washed with boiling water, dried, and weighed.

From the residue, the percentage of ash and, in substances very rich in nitrogen, the nitrogen percentage  $\times 6.25$ , is to be subtracted. The method gives fairly concordant results, and possesses the advantage that the solutions obtained, filter readily.—J. T. C.

*Linseed-Cake Fat, On the Iodine Number of.* B. A. van Kotel and A. C. Antusch. Zeits. angew. Chem. 1897, 210.

IN answer to the criticisms of Mastbaum (this Journal, 1897, 150), the authors remark that the various linseed oils extracted by them from the seed gave iodine numbers 181 to 187, or an average of 185; thus not differing greatly from 173 to 183, obtained by Mastbaum himself. They admit the possibility that, by warm or cold pressing and extraction, linseed oils may be obtained showing different iodine numbers, but, to their knowledge, this has never been actually tested; and the differences in Mastbaum's numbers for one and the same olive oil obtained at varying temperature and pressure, are insignificant. It is well known that the iodine numbers of linseed oils exposed to the influence of light and air decrease, but until it has been proved that, in well-kept cakes piled up one upon another, and so protected from light, an alteration of the oil, and therefore of the iodine absorption, occurs, Hubl's proposition must be accepted—that the age of the fat is without sensible influence on the iodine value. The iodine numbers, 166, 167, and 168, found by the authors for oils of extracted cakes, cannot, in their opinion, be fully explained by alterations which have possibly occurred in the oils in the cakes, and they therefore think that a determination of the iodine number of linseed-cake oils is always of importance as a test of purity.—L. J. de W.

**Beetroot-Sugar Analysis.** Resolutions of the Austro-Hungarian Chemists engaged in the Sugar Industry at the Meeting at Buda-Pesth, June 22, 1896. *Zeits. angew. Chem.* 1897, 123—125.

**Polarisation.**—For polarising substances containing sugar, only the half-shadow instrument is to be used. It is desirable to use the 100-mm. apparatus with contracted scale. During the observation, the polariscope must be in a fixed position, so far from the source of light that the polarising Nicol does not become heated. As source of light, a lamp with an intense flame is recommended; a triplex gas jet with metal chimney, lens and reflector; gas with the Auer burner, electric lamps, duplex petroleum lamps, &c. The chemist must satisfy himself as to the accuracy of the instrument by correct quartz plates, and of the invariability of the light before and after the observation; also of the accuracy of the weights, the polarisation flasks, the observation tubes, and the cover glasses. Scratched cover glasses must not be used. Results are to be expressed to the half of one-tenth per cent.

**Analysis of Raw Sugar.**—On opening the sample, the upper layer is to be removed with a spatula or a spoon, and discarded. The remainder is to be completely emptied into a porcelain dish and mixed. Any lumps may be easily crushed with a spoon. The sample is then replaced and the weighings made forthwith. For the polarisation of first products, at least the normal weight should be weighed out, dissolved in distilled water without the aid of heat, and, after clarifying, made up to 100 c.c. at the ordinary temperature (not too far from 17.5 C.). Of after-products it is advisable to take a multiple of the normal weight and make up to a corresponding volume. The flask must be standardised with water at 17.5 C. For clarifying and decolorising, basic acetate of lead may be used (3 parts of lead acetate, 1 of litharge, 10 of water), concentrated solution of alum, and Scheibler's colloidal alumina. Char and decolorising powder are absolutely excluded. For sugars polarising over 99, alum or colloidal alumina alone will suffice; for first products, 1 c.c. of acetate of lead and 1 c.c. of alum solution, and for after products, 2 to 3 c.c. of acetate of lead, 1 to 2 c.c. of alum solution for each 100 c.c. After making up to the mark and wiping out the neck of the flask with filter paper, the clarified sugar solution is well shaken, and the entire contents poured on to a dry quick-filtering filter. The first portion running through is poured away, and the rest, which should be perfectly clear, is used for polarising.

For determining water, only water-baths are to be used, with or without vacuum pump. Air baths are absolutely excluded. 10 to 15 grms. are dried for two hours. Sugars containing more than 3 per cent. of water are dried for a double period of time. After cooling in a desiccator, loss is taken as water.

Ash is determined by incinerating at least 3 grms., according to Scheibler's method, with pure sulphuric acid in a platinum dish in a muffle at as low a temperature as possible, a dark red heat. The ash should not be fused, and if, on being moistened with water, it shows sand or other mechanical impurities, a fresh test should be made. 10 per cent. is deducted from the ash before entering the result on the certificate.

Litmus is to be used for determining the alkalinity. It is to be stated in the certificate whether the sugar is alkaline, acid, or neutral.

**Invert sugar** is tested for qualitatively by dissolving 10 grms. of sugar in 25 c.c. of water, adding 100 c.c. of Soldani's solution, and boiling for five minutes, reckoned from the commencement of the boiling. In the quantitative estimation, the method of Herzfeld (*Z. Zuck.* 1886, 6) is followed. If less than 50 mgrms. of copper (corresponding to 0.05 per cent. of invert sugar) are obtained, 0.0 per cent. is to be entered on the certificate. An explanation of the reason of this procedure is to be endorsed on the certificate. If more than 0.05 per cent. invert sugar is found, the amount is to be expressed to two decimal places, the second figure being corrected by the third.

**Molasses and Osmose Water.**—At least 50 c.c. of molasses or osmose water should be freed from air by warming, and the mechanical impurities removed before the

density is determined by the pycnometer. The heating must be so carried out that the density is not affected. The density is to be expressed to five decimal places, and both old and new Beaumé degrees are also to be added. For the direct polarisation the dilution is to be so chosen that 100 c.c. of the clarified solution represents the half normal weight. Clarification is to be made with 10 c.c. of acetate of lead to the half normal weight, and no correction for the lead precipitate. The reaction to litmus is to be stated, and no complaints will be entertained unless the test is made immediately on receipt of the sample. For determining the ash, 10 to 20 grms. are carbonised, extracted, and evaporated, &c. unless otherwise desired. Invert sugar is to be determined by Herzfeld's method. When more than 1 per cent. of invert sugar is present a correspondingly smaller amount is used for the analysis. For calculating the results the tables of Meissl and von Hiller are to be used (*Zeits. angew. Chem.* 1890, 191 and 446). If less than 0.05 per cent. be present it is to be entered as absent.

**Analysis of Molasses by Inversion.**—In the determination of sugar by the Clerget method, clarification with lead acetate is not usual, but in the case of abnormal molasses and osmose waters where char does not suffice, clarification is effected by basic nitrate of lead. In this case Herles's constants are to be used in the formula for calculation, but the direct polarisation is to be obtained by clarification with basic acetate of lead. Of normal molasses and osmose waters the half normal weight is inverted in a 100 c.c. flask, according to the prescription of Herzfeld; after filling to the mark it is shaken up, and, if necessary, clarified by extracted char. The result is calculated by the formula 
$$\frac{100 S}{132.7}$$
 for the temperature of 20° C.; for other temperatures correction is made either according to the formula of Tuchschildt 
$$\frac{100 S}{142.7 - \frac{t}{2}}$$
 or by the formula—

$$120 = I + 0.0038 S (20 - t),$$

where  $S = P + I$ , i.e., the sum of the readings before and after inversion without regard to sign, and  $t$  the temperature of observation of the inverted solution in centigrade degrees.

Raffinose is estimated by inverting as above and using the formula  $Z = \frac{0.5124 P - I}{0.8340}$  and  $R = \frac{P - Z}{1.852}$ . In products containing more than 2 per cent. of invert sugar the determination of raffinose by the inversion method is to be abandoned. Abnormal products may be clarified by basic nitrate of lead under the conditions given above.

The analysis of char and manures is touched upon, and directions given with regard to samples. The resolutions were to come into force on Sept. 1, 1896.—L. J. de W.

**Sugar Solutions, Nitrate of Lead: The Use of, for Decolorising various.** H. Pellet. *Bull. de l'Assoc. des. Chim. de Suer. et de Dist.* 1897, 14, 794—796. (This *Journal*, 1897, 67.)

The substitution of nitrate of lead for basic acetate of lead, proposed by Herles, for decolorising the various sugar products to be polarised, is criticised by the author, who has not tried this reagent on beetroot molasses. He agrees with Weisberg that the advantage of having a liquor which, on inversion, is less coloured than by acetate of lead, is very slight. A few decigrams. of a special char will produce a very great decolorisation without absorption of sugar. Moreover, the use of nitrate of lead necessitates the use of caustic soda, and the formula to be applied for the inversion requires to be changed; this is a complication. Finally, the precipitate is so voluminous that a correction must be made.

When a lower polarisation is found on defecating with the nitrate than with acetate, it is necessary, as Weisberg remarks, to show that it is the former which is exact. The author holds that both are inexact if the filtered liquid is alkaline, as is generally the case; indeed, it may be more alkaline with the nitrate than with the acetate; the true polarisation is that given by the liquid freed from lead and polarised acid. This result is attained directly by using sulphurous acid, which is a powerful decoloriser, and likewise prevents coloration during the inversion. The liquor

freed from lead by sulphurous acid, and being acid, from sulphurous acid and acetic acid, is in a favourable condition for inversion, a partial or complete saturation of the hydrochloric acid by excess of acetate of lead need not be feared, whereas a destruction of sugar may occur from the action of the mixture of hydrochloric acid and nitrate, heated to 68° or 70° C. The author finds no advantage in substituting nitrate of lead and caustic soda solution for the procedure he has indicated for the analysis of molasses in general, both beet and cane, with the special modifications given for the latter.

Nitrate of lead and caustic soda were tried on cane molasses without any advantage as regards decolorisation; besides, the use of reagents of alkaline reaction should now be absolutely proscribed for the analysis of products of the cane containing reducing bodies (dextrose and levulose). The neutral acetate of lead should alone be used, and this also neutralised with acetic acid. Decolorisation is sometimes slight, and a very intense source of light should then be used. The author has given details relative to the use of acetylene for this purpose.—L. J. de W.

*Yeast, Quantitative Determination of, in Fermentation Experiments.* R. Kusserow. *Wochenschr. für Brauerei*, 1897, 14, 117—118.

The examination of a number of commercial yeasts shows—(1) that the amount of dry yeast substance increases with the specific gravity of the yeast; and (2) that the specific gravity of the dry yeast substance is approximately a constant (1.509), which can be calculated from either of the above values. In order to determine the amount of yeast formed in small laboratory experiments, all that is necessary is to siphon off the fermented liquor, wash the yeast repeatedly with distilled water, and then transfer it to a specific gravity bottle, which is finally filled with distilled water, and weighed. From the weight obtained, the specific gravity and, consequently, the amount of yeast can be calculated. This method may also be applied to other micro-organisms which subside when washed with water.—A. K. M.

*Wine, Detection und Quantitative Determination of Cane Sugar in.* P. Kulisch. *Zeits. angew. Chem.* 1897, 205—210.

The amount of acid prescribed by the official method for the estimation of cane sugar in wines (0.05 grm. HCl. to 50 c.c. of wine) suffices only for wines that have been diluted to one-fifth. Undiluted wines require about 1 c.c. of 25 per cent. hydrochloric acid, although under these conditions somewhat too much sugar may be found. An excess of 0.025 grm. per 100 c.c. is to be considered of no importance. For wines not diluted to one-fifth, but at least to half strength, 0.5 c.c. of HCl, sp. gr. 1.121, will suffice.

Inversion by means of oxalic acid is more convenient, 1 grm. being ample for wines diluted more than half; for less dilute wines, 2 grms. to 50 c.c. Oxalic acid has the advantage of not affecting the optical properties of the other sugars occurring in wines along with cane sugar.

—L. J. de W.

*Alcohol and Water, Distillation of very dilute Mixtures of.* Application to the determination of Alcoholic Solutions containing from 1 in 3,000 to 1 in 10,000. M. Nieloux and L. Bauduer. *Bull. Soc. Chim.* 1897, 17, 424—427.

Solutions of alcohol of strengths between 0.2 and 0.03 per cent. may be determined by means of a 2 per cent. solution of potassium bichromate, the yellowish green colour due to excess of bichromate being easy to distinguish from the bluish-green solution otherwise obtained.

In the distillation of ordinary dilute alcohol, all the alcohol is contained in the first third of the distillate. The authors find that very dilute solutions (0.2 and 0.03 per cent.) also behave in a similar manner. In solutions of this strength they find that (1) the first twentieth of the distillate contains about 50 per cent. of the alcohol, (2) the more dilute the solution the greater is the percentage of the total alcohol contained in any fraction distilled. (3) the alcohol in the 0.2 and 0.1 per cent. solutions is all contained in the first third, the alcohol in the 0.03, 0.02, and 0.01 per cent. solutions in the first quarter of the distillate.—A. C. W.

*Ethyl Alcohol and Acetic Ether, Volumetric determination of Mixtures of.* B. Knillhoff. *Ber.* 30, 741—743.

Alcohol is volumetrically determined by permanganate, or by oxidation with chromic acid. The latter method is preferable, because the products of the first process are unknown. The author, in employing the chromic acid method according to the directions of Boureaux, always found 1—1.5 per cent. of alcohol too little; after varying the duration of the reaction and the strength of acid and bichromate, he finds that the following are the necessary conditions:—25 c.c. of alcohol solution, containing about 0.1 grm. of alcohol, are placed in a thick walled flask of 200 c.c. capacity, and 25 or 50 c.c. of chromic acid solution added, the cork is tied down, and the flask heated on the boiling water-bath for six hours. The bichromate solution contained about 1 grm. in 100 c.c.; the sulphuric acid was diluted with five or six volumes of water. After cooling, the contents of the flask are washed out, potassium iodide added and the liberated iodine determined by thiosulphate. The acetic acid formed is not further oxidised—

In the oxidation of acetic ether by chromic acid, saponification first takes place and then the alcohol produced is oxidised as above. According to the author's results the oxidation method is to be preferred to saponification with baryta.

In the analysis of mixtures of alcohol, acetic acid and acetic ether, free acid was determined in one portion, ether in a second by saponification, and total alcohol in a third by oxidation.—A. C. W.

*Coffee Beans, Determination of the Weight of the Layer of Caramel on, after Roasting with Sugar, and upon the Examination of Coffee in General.* W. Fresenius and L. Grünhut. *Zeits. Anal. Chem.* 36, 225—233.

The methods of König (*Zeits. f. angew. Chem.* 1888, 631), Neubauer, Stutzer (*Zeits. f. angew. Chem.* 1888, 701), and of Hilger, were compared upon four different kinds of coffee beans, each of which kinds was roasted without sugar to three different grades, *viz.*, until it had lost 15 per cent., 18 per cent., and 21 per cent. respectively, and each of which was also roasted with additions of 7½ per cent. and 9 per cent. of sugar respectively.

Hilger's method, which is the one preferred, was carried out as follows:—10 grms. of whole beans were covered with 100 c.c. of dilute alcohol (equal volumes of 90 per cent. alcohol and of water), and allowed to stand for half an hour at the ordinary temperature, after which the alcohol was poured off, and another portion of 100 c.c. of the same strength, added, and the coffee allowed to stand for a second period of half an hour, when the liquid was again decanted. This was repeated a third time with a third portion of alcohol, and then the three decanted portions of spirit were united, made up to a volume of half a litre, an aliquot part of this taken, evaporated to dryness, dried at 100° C. and weighed, after which it was incinerated, and the residual ash weighed.

By operating in this way upon coffee, which had been roasted without sugar, the amount of soluble extract derivable from the pure coffee beans was determined, and the difference between this amount and the total amount of extract obtained from the coffee beans coated with caramel, gave the weight of the caramel due to roasting with sugar. The authors found by this method that the average percentage of extract from pure roasted coffee beans was 1.15 per cent., equal to 0.85 per cent. of ash-free extract. After correcting by these amounts, the extracts derived from the caramelised coffee, the latter yielded from about 2.1 per cent. to 4.4 per cent. of extract, equal to, from 2 per cent. to 4 per cent. of ash-free extract. The authors point out that before accepting these or any figures as true average values, many more determinations should be made. For tables and further details, the original should be referred to (see also this Journal, 1889, 822).—Jl. S. P.

*Sugar in Chocolate and Foods, Determination of.* H. Pellet. Bull. de l'Assoc. des Chim. de Sucre et de Dist. 1897, 14, 790—792.

A. ROQUES in a note on the determination of sugar in chocolate (*loc. cit.* Dec. 1896) advises the preparation of a solution of 15 grms. of chocolate in about 90 c.c. of distilled water, heating to 40 °C. and stirring. 15 c.c. of 10 per cent. basic lead acetate are added and the solution filtered. 70 c.c. of this liquid are taken, and sulphate of soda and acetic acid added to eliminate the lead. But, as Stammer demonstrated many years ago, liquids containing simultaneously lead and saccharine matters, retain in solution some of the sulphate of lead, the remainder of which has been precipitated by acetic acid. As chocolate often contains notable proportions of glucose, it seems preferable to use "neutral lead acetate," neutralised with acetic acid, as for cane products, and to precipitate excess of lead by sulphurous acid. Even large quantities of sulphurous acid do not affect the determination of reducing sugars by means of Fehling's solution. The author used 2 grms. of crystallised sodium sulphite with 5 c.c. of Fehling's solution, and found that it required the same amount of a glucose solution, with and without sulphite; this being more than 20 times the amount of sulphite that would be present. The only precaution to be taken is to add a little soda with the copper liquor to saturate the free acid.

To determine the total sugar and glucose, Roques proposes heating 56 c.c. of the solution for three hours on a water-bath; the acidity due to the acetic acid sufficing to produce inversion. The procedure appears dangerous to the author, as the acidity may be insufficient to transform all the crystallisable sugar, and the method of heating is uncertain. It is better to plunge the flask into a boiling water-bath, and to note the temperature of the liquid inside the flask. A quicker method is possible. If dextrin is suspected, the sugar may be inverted by heating the solution to boiling for one or two minutes after adding  $\frac{1}{2}$  per cent. of hydrochloric acid. The sugar alone is inverted, the action of the acid on the dextrin commencing only after a much longer time and with a greater acidity. This quantity of acid is quite sufficient to convert, on boiling, all the sugar present. It is advisable to use the neutralised "neutral acetate" of lead for all food stuffs containing glucose, for the basic acetate may not only precipitate reducing sugars, as levulose, but an excess may affect the polarisation.—L. J. de W.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Calcium Carbide from Calcium Tartrate, Production of.* S. Zinno. Boll. Chim. farmac. 1896, 35, 555; Chem. Zeit. Rep. 1897, 21, [9], 67.

THE author obtained, by heating crude calcium tartrate, which forms the sediment in wine casks, in a cast-iron retort to 500 °C., a dry, hard, grey, spongy mass, which on contact with water developed acetylene.—A. S.

*Cochineal [Oxidation of].* C. Liebermann and H. Voswinckel. Ber. 30, 688—691.

By oxidising the colouring matter from cochineal or cochineal carmine in an alkaline solution with potassium persulphate and extracting with ether, a residue is obtained easily soluble in water. This consists of a mixture of acids, two of which (neither containing nitrogen) were separated by means of their lead salts and designated cochineallic acid and coccic acid. The former  $C_{10}H_6O_4$  (?) is precipitated from methyl alcohol by chloroform in thin white needles melting at 225 °C. The aqueous solution gives a red coloration with ferric chloride and with bromine water, a white precipitate melting at 226° °C., having the composition of a trifluoro-cresotic acid,  $C_6Br_3(OH)(CO_2H)$ . Coccic acid,  $C_{11}H_6O_4$ , melts at 293 °C. and crystallises from dilute alcohol in needles. It gives with ferric chloride a similar coloration to cochineallic acid, but somewhat more violet, and may possibly be a cresol dicarboxylic acid.

—T. A. L.

*The "Shinia" Leaves of Cyprus.* Imp. Inst. J., May, 155.

A DESPATCH has been recently received from the Chief Secretary of Cyprus enclosing translations of pamphlets by M. P. Gennadius, Director of Agriculture in that island, on the industry connected with the cultivation of the shinia and laurel shrubs. *Pistacia lentiscus* is a shrub that grows abundantly in most parts of Cyprus, and is called in the island "shinia"; a variety of this shinia is the mastic shrub of Scio, the leaves only of which have a commercial value, serving as a tanning and painting material. From the wood of the shrub, charcoal of good quality is made, and from its seed oil can be extracted, which is fit, not only for burning purposes, but, in case of necessity, for food as well. For sometime shinia leaves were exported from Cyprus to England in small quantities by the Cyprus Company, but the principal market for shinia leaves is Palermo, in Sicily, to which port there is an annual exportation from Tunis of 10,000 tons; they are there used chiefly for the adulteration of sumach (*Rhus coriaria*), which is grown in large quantities in Sicily, and is thence exported to England and France. A good quality of shinia leaves is also consumed at Lyons as a dyestuff for silks.

*Aluminium Nitride [Ammonia from Nitrogen of Air], Preparation and Properties of.* L. Franck. Chem. Zeit. 1897, 21, 263.

THE author has previously shown in conjunction with A. Rossel (this Journal, 1896, 273) that when aluminium powder is heated with calcium carbide, the product possesses the property of combining with atmospheric nitrogen. Aluminium nitride ( $Al_2N_3$ ) is now prepared by mixing powdered aluminium with a known proportion of calcium carbide and heating the mixture before a blow-pipe flame in a porcelain crucible. When the reaction is finished, a spongy greyish-white or yellow product remains in the crucible, which does not absorb nitrogen until it has been exposed to the air for some hours. The nitride smells faintly of ammonia. In boiling water, ammonia is slowly liberated, but in caustic alkalis, generated in large quantities. One of the products prepared in the above manner contained 15—20 per cent. of nitrogen. A preparation containing more nitrogen could not be obtained by this method nor by leading pure nitrogen over the mixture. A product which absorbed a considerable amount of nitrogen was obtained by heating aluminium powder with dry slaked lime.

The author is carrying out experiments on the value of aluminium nitride as a nitrogeneous manure. He thinks from his results that it can be used directly as such, and that the loss of ammonia is in any case very small.—J. L. B.

*Gold, Action of Phosphorus on.* A. Granger. Comptes Rend. 1897, 124, 498—499.

By heating finely-divided gold at a temperature of about 400° in the vapour of phosphorus and cooling rapidly, the author has prepared a compound  $Au_3P_4$ , which decomposes when heated in contact with air, and even in a current of carbon dioxide, at the temperature at which it is formed.

—J. S.

*Highly Purified Substances, Observations on the Properties of some.* W. A. Shenstone. Proc. Chem. Soc. 1897, [178], 2—3.

1. THE author has compared the behaviour of oxygen under the influence of the silent discharge of electricity when saturated with water vapour, and when carefully dried. The results show that, contrary to the statement of previous investigators, oxygen is most freely converted into ozone when wet, and that well-dried oxygen yields only a very minute percentage of ozone. The results obtained also show that the ozone in ozonised oxygen is far more stable in the presence of water vapour than in its absence; that is to say, the change by which ozone is converted into oxygen is very greatly retarded by the presence of moisture.

2. Chlorine prepared by the electrolysis of silver chloride, and also carefully purified bromine and iodine, have been dried by very thorough treatment with prepared phosphoric

oxide, and then presented to the action of mercury prepared for the purpose by several distinct methods and thoroughly dried. In every case the metal and the halogen interacted instantly and rapidly.

3. Highly purified chlorine, when submitted to the silent discharge of electricity, does not undergo condensation.

4. The abnormal expansion of chlorine which has been described by several observers appears to depend upon the presence of impurities in the chlorine.

*Zinc Dust as an Oxidising Agent in Presence of Acetic Acid. [Preparation of Camphoric Anhydride.]* O. Aschan. Ber. 30, 657–658.

By the action of zinc dust and acetic acid on benzoin, Sudborough noticed the formation of benzil, and the author quotes another instance in which zinc dust acts as an oxidiser. He observed that when camphorquinone—

is dissolved in six times its weight of glacial acetic acid, and treated with zinc dust, heat is evolved, and the golden yellow solution rapidly decolorises. On evaporating the filtered solution to half its bulk and adding water, a copious crystalline precipitate is obtained, which, after two crystallisations from alcohol, melted at 220° C., and possessed all the characteristics of camphoric anhydride.—T. A. L.

*Antimony Tetroxide, Decomposition of, at High Temperatures.* H. Baubigny. Comptes Rend. 1897, 124, 560–562. (See page 170, col. 1.)

ANTIMONY pentoxide, when heated, is perfectly stable at temperatures not exceeding 357° C.; but from 440° C. upwards to a faint red heat, it is slowly reduced to antimony tetroxide ( $\text{Sb}_2\text{O}_4$ ) with evolution of oxygen. The transformation takes place rapidly at 750°–800° C., at which temperature the tetroxide formed is stable. At higher temperatures, equal to or exceeding that at which silver fuses, the tetroxide, is, however, in its turn reduced to trioxide, and at the melting point of gold, this conversion is rapidly effected. Antimony tetroxide cannot, therefore, be regarded as a “fixed” body; at least in so far as concerns its behaviour when strongly heated.—H. T. P.

*Starch, Fixation of Iodine by Rice and Wheat.* G. Rouvier. Comptes Rend. 1897, 124, 565–566.

THE author has previously shown (Comptes Rend. 114, 1366; 117, 461; and 118, 743) that when starch (rice or wheat) is suspended in water and treated with iodine, definite compounds are produced, either  $(\text{C}_6\text{H}_{10}\text{O}_5)_{16}\text{I}_2$ , or  $(\text{C}_6\text{H}_{10}\text{O}_5)_{16}\text{I}_3$  being formed, according as the starch or the iodine is employed in large excess; but that between these extremes, the quantity of iodine absorbed increases regularly with the quantity of iodine employed. The numerical results before obtained, the author considers, admit of an interesting theoretical interpretation. On the assumption that, between the limits already mentioned, compounds with three and four atoms of iodine are successively formed, and that these bodies possess the property of dissolving a certain proportion of iodine, it is found that the iodine thus dissolved (by the starch iodide), bears a constant ratio to the iodine remaining in solution in the supernatant liquid, in accordance with the well-known law as to the distribution of a soluble substance between two immiscible solvents. It appears, therefore, that iodine, when not present in sufficient excess to produce the compound  $(\text{C}_6\text{H}_{10}\text{O}_5)_{16}\text{I}_3$ , is fixed by starch, partly in definite combination, partly in a dissolved state.

—H. T. P.

*Iodine Spring, Analysis of Water from a recently discovered.* A. Lipp. Ber. 30, 309–312.

THE water analysed, is that of a spring (Marienquelle) discovered in 1891 in the neighbourhood of Fussen, in the Bavarian Algan.

The water, which is medicinally valuable, is clear and colourless. Its temperature, summer and winter, is from

7–8° C. and its density 1.00216. The water possesses a slight characteristic odour, due to dissolved hydrocarbons, a slightly salty taste, bitter to alkaline. Its reaction is slightly alkaline.

In sealed vessels the water remained unchanged after two years; exposed to the air, however, it turns yellow, owing to the separation of iodine. A continuous evolution of gas bubbles was noticed in the spring, the gas being methane.

In addition to the complete analysis, estimation was also made from time to time of the total solids; the variation in the amount of these was only slight, as the following figures show:—

			Grams.
In October 1891	the residue per litre was	2786	
“ July 1893	“ “ “	2780	dried at 180°.
“ April 1894	“ “ “	2752	

The metals found in the water were: in larger quantities, sodium, calcium, and magnesium; in smaller amount, iron, lithium, aluminium, and potassium; in minute traces, barium, strontium, &c. These metals were chiefly combined with chlorine, iodine (0.015 gram. per litre), bromine (0.012 gram. per litre), and carbonic acid; to a slight extent with silicic, phosphoric, boric, and sulphuric acids. In addition it contained free carbonic acid, marsh gas, and some solid organic substance.—J. T. C.

## New Books.

EINFÜHRUNG IN DAS STUDIUM DER ALKALOIDE, mit besonderer Berücksichtigung der vegetabilischen Alkaloide und der Ptomaine. Von Dr. LILLO GUARESCHI. Mit Genehmigung des Verfassers. In Deutscher Bearbeitung herausgegeben von Dr. HERMANN KUNZ-KRAUSE. Zweite Hälfte. (Schluss des Werkes.) 1897. Hermann Heyfelder, Schönebergerstrasse 26, Berlin, S.W. Price M. 18. H. Grevel and Co., 33, King Street, Covent Garden, London.

THE appearance of the German translation of the first half of this work was noticed in this Journal, 1896, 926. The appearance of the second half is now announced. It is a quarto volume, unbound, and simply a continuation of Part I., the text extending from page 305 to 632. At the end there is an alphabetical index filling nearly 18 pages, and a table of contents.

SOME UNRECOGNISED LAWS OF NATURE. An Inquiry into the Causes of Physical Phenomena, with special reference to Gravitation. By IGNATIUS SINGER and LEWIS H. BERENS. With Illustrations. John Murray, Albemarle Street, London. 1897. Price 18s.

8vo volume, containing preface, table of contents, subject-matter filling 477 pages, and an alphabetical index. The text is illustrated by 67 woodcuts, and is subdivided into four books, each of which is separately divided into chapters. Book I. Chap. I. Introduction. II. Methods of Inquiry and Sources of Error. III. Methods of Verification. IV. The Basic Principle of the Current Theory of Gravitation. Book II. Chap. I. Persistence. II. Relative Resistance. III. Equalisation. IV. General Tendency of Nature. V. and VI. On “Forces.” VII. “Matter” and “Energy.” VIII. Conservation of Energy. Book III. Phenomenology, or the “Interconvertibility of Forces.” Chap. I. Introductory. II. Acceleration and Retardation. III. and V. Heat. IV. Molecular Physics. VI. and VII. Electricity. VIII. Conduction. IX. Induction. X. and XI. Action at a Distance. XII. Magnetism. XIII. Polarity of Magnets. XIV. Para- and Diamagnetism. XV. Summary and Conclusions. XVI. Hardness and Solidity. Book IV. GRAVITATION. Chap. I. Introductory. II. Teachings of Newton. III. Review of the Newtonian Theory. IV. Definitions and Principles of Motion. V. Gravity. VI. The Earth. VII. Sun and Earth. VIII. Causes of Seasons and Variable Days and Nights. IX. and X. Diameter of the Earth’s Orb. XI. Suggestions concerning Sun Spots. XII. Testimony of the Stars. XIII. Precession and Nutation.

## Trade Report.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### THE GERMAN LEATHER INDUSTRY.

*Board of Trade J., May 1897, 542.*

In a despatch to the Foreign Office, dated 17th April last, Viscount Gough, Her Majesty's Chargé d'Affaires at Berlin, forwards a précis, by the Commercial Attaché of the Embassy, of a book lately published, called the "*Leder-Herold, 1897*," which is, practically, a report on the whole leather industry of Germany. This is one of the most important of German industries, and may be said to occupy the third to fourth place, if all its branches are taken into account, and it is one that is daily expanding in every direction. According to the census of 11th July 1895, the number of persons engaged in it were 596,717, of whom 433,586 were occupied in the boot and shoe trade, 74,839 in making saddlery, harness, &c., 47,480 in tanning, and 16,278 in the glove trade. The commerce in hides and skins is immense, and is one of the leading branches of trade, as is also that of tanning materials. In 1895 the value of the imports of the former was 7,297,700*l.*, and that of the exportation amounted to 2,579,050*l.* Besides this, 1,549,500*l.* worth of tanning materials were brought into the country. The exports of worked-up hides, leather, and oil-cloth were valued at 4,925,450*l.*, and those of leather, harness, and pocket articles, 4,914,350*l.*

In consequence of the immense increase of the leather manufacture in the Hamburg neighbourhood, that town has become the emporium of the Continent for hides and tanning materials, and has quite eclipsed Havre and Antwerp in that respect.

There seems to be no doubt that this industry has a still greater future before it. It is as yet in a partly transition state from one of primitive and hand methods to one of mechanical and chemically-aided production on a large scale. The consumption of leather wares is greatly on the increase. At the present time it amounts to about 20,000,000*l.*, to which must be added the exportation of leather and manufactures thereof, which in 1895 were valued at 10,000,000*l.* The German army consumes alone an immense quantity of leather goods. 500,000 pairs of boots are yearly supplied to them; and further, there are large orders for resoling. The manufacture of machine-made boots and shoes has advanced greatly, and is now a large independent branch of the whole.

As regards leather and its manufactures, Germany has now become fairly independent of foreign supplies, and will daily become more and more so. The rise of this industry suffered greatly from foreign competition; and the tanning trade could not formerly satisfactorily compete with North American manufacturers of leather, who imported hides tanned with hemlock—a very cheap process. It was this circumstance that led to a great agitation on the part of leather manufacturers and tanners in Germany for heavy protective duties. This demand was accorded them by the new tariff of 19th July 1879, by which the import duties were immensely raised. Prior to 1878 the quantity of raw hides imported had increased from 400,000 centners to 800,000 in that year. Since then the leather industry has grown and flourished, and the greatest care has been taken to make use of the newest methods of production, which have all been carefully experimented with. Particular attention has been paid to every detail in manufacture for the perfecting and cheapening of processes. The use of "*Quebracho*" wood as a tanning medium has caused a revolution in production, and, particularly in the neighbourhood of Hamburg, many special works for its use have been erected.

The technical side of leather production has had a great influence, from the attention bestowed upon it. Among the newest creations of the tanners' guilds are the establishment

of a special trade school and technical institute. In Freiberg, in 1889, a tanning school was founded by the Saxon leather industry. A chemical technical laboratory was also started in 1881. Both these institutions have brought the production of leather to a wonderful pitch of scientific perfection. In many other special branches of this trade there are schools of the same nature—as, for instance, for sewing gloves, making saddlery, &c.

The year 1895 was in two respects unsatisfactory for the leather industry: firstly, because of the unexpected rise in price of leather and hides; and, secondly, from the uncertainty as to the result of the proposal to place a duty on the importation of "*Quebracho*" wood and other foreign tanning materials, which was supported in the Reichstag by a powerful party interested in improving the position of the tanning materials of Germany. The "*Bundesrath*," however, rejected the resolution of the "*Reichstag*." It has since been proved that the duty-free admission of "*Quebracho*" is necessary to the maintenance of that country's competition in the world's markets, and that any duty making leather manufacture dearer would do much harm. It was also undesirable, because that wood is becoming scarcer, and consequently German tans will in time acquire, naturally, a better price.

An attempt has been made last year to improve the statistics relating to leather industries, to obtain a reduction of railway freights for salted hides (it is believed they will come into force on 1st April 1897), and to still further apply scientific knowledge to all processes. Dr. Gürke, of the Botanical Museum in Berlin, has taken steps to obtain a collection of the world's tanning materials, which will be exhibited with details as to the production, use, and price.

The tanning school in Freiberg, Saxony, which was opened on May 1st, 1889, is the only one of its kind in Germany, and was then the only one in the world. Since that date, however, similar schools have been established in Vienna, Hungary, and North America, and Württemberg and Rotterdam have both planned such schools.

The object of this Saxon tanning school is to teach the principal technical processes, all improved methods and technique, and the trading methods of dealing with raw material, &c. The special points of instruction are as follows:—Tanning and preparation of hides, with practical examples; scientific lectures on tanning; general chemistry; practical chemistry in tanning trade; chemical experiments; tanning methods, "*tawing*" ("*weissgerberei*") by fat and minerals; colouring of leather; physics; microscopic demonstrations; knowledge of machines; drawing; book-keeping; trade accounts; trade apprenticeship; German language, correspondence and business letters; first help to be given in accidents.

The course lasts one year. The fees for Germans are 10*l.*, and for foreigners, 17*l.* 10*s.*; they are payable in two instalments. A further 1*l.* 5*s.* is charged for use of the laboratory and for tanning apprenticeship. Rooms with or without board can be had; and at a cost of from 25*l.* to 45*l.* a year lodging and food can be had for the year. Prospectus is sent on application. For theoretical instruction there are collections available to students which cover all branches of the trade. There is a library of 400 volumes, in which are to be found the chief publications on this industry in all languages.

From 1889 to 1895, 173 Germans and 133 foreigners attended the school. (In the list of students for last year not one Englishman figures.)

The "*Leder-Herold*" for 1897 also treats of the course of study in the chemical technical laboratory of the Society of German Tanners, which is in Berlin, and was the first of its kind in Germany. A list is also given of the technical schools for boot and shoe makers, saddlers, harness makers, and paperhangers, and for sewing of gloves.

In addition, there are statistics most valuable to the leather trade, dealing with all branches for many years back, and an enumeration of the duties of the principal countries on leather and leather manufactures—including Germany, Belgium, France, Greece, Italy, Norway, Austria-Hungary, Roumania, Russia, Sweden, Switzerland, and the United States.

## GENERAL TRADE NOTES.

## GUNPOWDER AND DYNAMITE IN GREECE.

*Bd. of Trade J., May 1897, 545.*

At the present time in Greece, according to official Greek statistics quoted in the *Bollettino di Notizie Commerciali*, there are 29 manufactories of powder—i.e., three (the most important) in the neighbourhood of Athens, 15 at Dimitzani, one at Argos, and 10 at Phthiotide,—of which five only are at work. The largest is that of the limited company "Ελληνικός πυριδοποιός," which turns out also the most dynamite, and is, besides, the only one to manufacture sulphate of iron and sulphuric acid for the demand of native manufacturers.

Two other establishments, at the foot of Mount Hymettus, make dynamite only: one belongs to a private individual, and the other, the larger, to the "Société Anonyme Franco-Hellénique de Matières Explosives et de Produits Chimiques," the headquarters of which are at Paris. A few years ago a factory for cartridges was established in the neighbourhood of Athens, which produces annually more than a million cartridges for military and sporting purposes, besides a large quantity of wads.

The total value of the manufactures is estimated at 2,000,000 drachma (80,000*l.*). The annual output of powder of all sorts for any purpose is 675,000 oekes—about 1,917,000 lb., and of dynamite 90,000 oekes, or about 255,600 lb., and the manufactories can increase their output if required. The greater amount of the production is for home consumption, but some is exported. The importation of these products decreases year by year, as can be seen from official statistics.

## THE MOUNT PLEASANT PHOSPHATES IN TENNESSEE.

*Eng. and Mining J., April 24, 1897, 404.*

Although the Mount Pleasant phosphate deposits in Tennessee have been opened less than a year there are nine companies at work in it already. The *American Fertiliser* says that experience has already shown that a grade of rock thoroughly acceptable to the domestic market is produced without any treatment other than simply drying the rock as it comes from the ground and screening this product over a half-inch screen after crushing. The drying may be done by burning on wood, which must be resorted to in winter, but during the summer months the rock loses its moisture readily in the sun, and sun-drying has proven to be quite sufficient. In fact, some manufacturers claim that the sun-dried product works better on acidulation than the hot-air-dried rock, the explanation for this being that too much carbonic acid is driven off in the kiln-drying process.

The best posted authorities claim that if any of this rock is to be exported, however, it must be thoroughly washed to reduce the percentage of iron and alumina. There seems to be no doubt in the minds of any persons who have investigated the rock, that a product can be had that will run between 77 per cent. and 80 per cent. bone phosphate, but the great question so far has been how to reduce the iron and alumina below 3 per cent. in cargo lots. Preparations for export business are, however, being made. (See also this Journal, 1896, 837.)

## BASIC SLAG IN GERMANY.

*Eng. and Mining J., May 8, 1897, 448.*

During the year 1896 there were 83,765 tons of Thomas or basic slag imported into Germany, while the exports, chiefly to Belgium, were 134,257 tons. The fertiliser manufacturers now use large quantities of this slag instead of buying imported phosphate rock, and the total consumption of basic slag in Germany in 1896 is estimated at 800,000 tons.

## VERONA EARTH.

*Ch. of Comm. J., April 1897, 89.*

A great quantity of terra di Verona is now exported to Great Britain, Malta, and other States, for the manufacture of colours. It goes by the name of Green Earth, Verona,

or Veronese Earth. In the event of British colour manufacturers wishing to import it direct, British Consul de Zucato gives the names of the best firms from whom the earth may be purchased. Such names were courteously given him by the Chamber of Commerce there, viz., Signor Giovanni Colombari, Signor Pietro Bonomi, and Signor Domenico Brauzani, all living at Verona.

## THE SUMACH TRADE OF ITALY.

*Ch. of Comm. J., April 1897, 88.*

The French Consul at Palermo directs attention to the diminishing export trade of his province in sumach, which, he says, is undoubtedly due to the conduct of the exporters in stooping to adulteration for the purpose of increasing their profits. Mastie tree leaves, which are found on the Tunisian coast in great abundance, and which also contain a certain quantity of tannin, can, it appears, be mixed with sumach leaves without their presence being detected. This mixture has been habitually made in the proportions of 10 to 20 per cent. for sumach styled as first quality, sold in leaves at the rate of 21 to 26 frs. per 100 kilos, and in proportions of 40, 50, and even 75 per cent. for sumach of second quality, selling at 18 to 23 frs. per 100 kilos, delivered f.o.b. Palermo. Buyers have thus been rendered mistrustful, and the demand has diminished in a marked manner. To remedy this state of things and to remove the discredit which has fallen upon the trade, the Italian Government thought it *apropos* to levy a high duty on mastie leaves of Tunisian origin, and to instruct the provincial Agricultural Institute to seek the best means of discovering the adulteration to which sumach is subjected. As a result of this action, Signor Matteo Spica describes a scientific method of easily discovering the presence of foreign bodies in sumach, either in leaf or in powder. Pure sumach gives on analysis a colouring substance of which the intensity is invariable. When the colour sample submitted to examination does not correspond to the true type the adulteration of the sumach can be affirmed.

## EFFECTS OF THE NEW GERMAN SUGAR TAX.

*Export, 19, [14], 185—187.*

Disappointed with the results of legislative interference, a number of the German raw sugar makers proposed to form a syndicate to maintain the price of the article by restricting the output and sale, but, instead of the expected 50 per cent. of makers, only 38 per cent., representing 24 per cent. of the total annual production, joined the association, so no practical result is likely to ensue. A second syndicate, composed of refiners, was also projected for the purpose of inducing the first syndicate to supply none but the associated refiners, and a premium of 2 marks per 100 kilos. was to be given to purchasers dealing exclusively with the syndicate, but this proposal came to nothing. A similar combination of sugar makers in Austro-Hungary roused considerable opposition on the part of the Bohemian beet growers; so that the effects of the German sugar law has produced dissatisfaction all round, the Eastern German States being opposed to bounties at all.

In view of these manifestations, it is considered sugar premiums should be abolished, since, as at present bestowed, they are insufficient to afford any assistance, and it is assumed that any steps taken in this direction by Germany would soon be followed by France and Austro-Hungary.

—C. S.

## THE MINERAL RESOURCES OF WYOMING.

*Board of Trade J., May 1897, 555.*

Deposits of soda covering vast tracts of country, formed by springs, containing a quantity of soda in solution, exist in the State of Wyoming. Under the influence of an excessively dry atmosphere, the solution evaporates and the soda is deposited in the form of crystals, giving the lakes the appearance of immense fields of ice. There are several of these lakes, some of them having an area of 197 acres, and a depth of from three to four yards. The Belgian Consul at Denver, in a recent report to his Government, states that the preparation of this soda for the market

comes to 16s. per ton, the cost of carriage from Wyoming to Chicago is 24s. per ton, and the soda ash is worth 4l. per ton at New York. Several manufactories are already at work near these lakes, and others are spoken of. These natural depôts probably contain many million tons. It may be noted that 108,169 tons of soda are annually employed in the making of sheet glass in the United States.

At Casper and Lander, in a barren region in the centre of the State, are immense deposits of petroleum, the excellent quality of which is well known: its purity is such that the railway companies use it in a raw state. Several companies have already undertaken the sinking of a certain number of oil wells, and the results obtained appear to show that the petroleum industry is likely to develop to immense proportions.

Coal occupies an important place among the mineral resources of the State, and is found of excellent quality throughout. There is also a bituminous coal which is worked into coke of good value and finds a regular place on the market.

The coal mines are worked on a large scale: during 1895 the output was 2,202,000 tons, of a value of 637,700l.

Immense quantities of nickel and asbestos have also been recently discovered, and asphalt, kaolin, and mica exist in several depôts.

#### GERMAN SPIRIT DRAWBACK.

*Chem. and Druggist, May 22, 1897, 819.*

A German Imperial order has just been published naming certain tinctures and other spirituous preparations, in the preparation of which duty-free alcohol may henceforth not be used at all, or used only if the goods are sold for medicinal purposes exclusively. The preparations for which the employment of duty-free alcohol is forbidden are:—Essence and spirit of anise, essence of peppermint, hair-spirit (*Spiritus crinalis*), and tinctures of alkanet (acid), pimento, ambergris, ambergris and musk, cordial tincture (*Tinctura asperula*), tinctures of cochineal, turmeric, tonca-bean, iwa, orris, pepper, quillaia, caramel, and all compounds of ether. Those in which duty-free alcohol may be used, provided the articles are employed for pharmaceutical purposes only, are:—Aromatic vinegar, extract of calamus, alcoholic extract of rhutany, *Mistura oleo-balsamica* (Hoffmann's life-drops), solution of salicylic acid, Spir. ammon. aromat. B.P., spirits of angelica, lavender, rosemary, soap (*Sp. sapon.*), and serpyll linus and tinctures of tola, benzoin (simple and comp.), catechu, guaiacum wood, kino lavender (simple and comp.), musk, myrrh, pyrethrum, quassia, ratanhia (sweetened), sassafras, and sumbul. When tinctures enumerated in the first schedule are exported they are subject to drawback.

#### AUSTRALASIAN SULPHUR AND ARSENIC.

*Chem. and Druggist, May 22, 1897, 820.*

Arsenic is now produced in two qualities (white, containing 95 per cent., and grey, containing 92 per cent. of arsenious oxide) at the smelting works at Spottiswoode, near Melbourne. A small quantity of it is reported to have been shipped to London recently. The recent advance in the price of Sicilian sulphur has also led to the renewed working of the large New Zealand deposits. Hitherto the Australian sulphuric acid makers have imported their supplies from Italy and Japan, but on March 20, 320 tons of sulphur arrived at Sydney from the North Island of New Zealand, and another cargo of 600 tons is on the way.

#### CLOSE OF THE PETROLEUM INQUIRY.

*Chem. Trade J., May 22, 1897, 352.*

Although the Petroleum Committee have finished taking evidence, it is still uncertain whether they will be able to state the result of their inquiry this session. They have adjourned until after Whitsuntide, in order that Sir Vivian Majendie may have time to prepare a *priceis* of the evidence as the basis for a draft report; but, in view of the varied and important issues that have been raised, a considerable period will be needed for formulating and considering the conclusions and recommendations, and in the circumstances

it is quite within the bounds of possibility that the committee may have to be reappointed next year to bring their labours to a conclusion. The principal difference of opinion, when the committee come to consider their report, will probably be as to the suggested raising of the flashing point of petroleum. Other important questions to be considered refer to the manufacture of lamps and the regulations concerning storage; but these are not expected to arouse serious controversy.

#### THE MINERAL PRODUCTION OF GERMANY IN 1896.

*Eng. and Mining J., May 8, 1897, 451.*

The mineral production of Germany, or at least the principal items, for the year 1896, is given by *Glückauf* in a recent issue, the table there presented being taken from advance notes of the official returns. The statement shows generally an appreciation in prices as well as an increase in quantities. Thus, among the metals, copper increased from 903 to 995 marks per ton, and zinc from 201 to 220 marks. The average value of pig iron in 1895 was 43·32 marks (10·83 dols.) per ton, and in 1896 it was 46·98 marks (11·75 dols.) per ton. The lightest increase in values was in coal, the average price last year being reported at 6·92 marks, against 6·81 marks in 1895; while brown coal (lignite) was valued at 2·27 marks, or less than in 1895, when the average was 2·34 marks.

The general summary of the production of minerals for 1896, as compared with the previous year, is as follows, in metric tons:—

—	1895.	1896.	Changes.	Per Cent.
Coal .....	79,160,276	85,639,861	Inc. 6,479,585	8·2
Brown coal (lignite) ...	21,788,363	26,797,880	Inc. 2,009,517	8·1
Petroleum .....	17,051	20,335	Inc. 3,334	19·6
Rock salt .....	686,940	755,833	Inc. 68,893	10·0
Kainit .....	680,174	856,290	Inc. 176,116	25·8
Other potash salts .....	841,748	924,140	Inc. 82,392	9·8
Iron ores .....	12,349,600	11,162,315	Inc. 1,812,715	14·7
Zinc ores .....	706,123	729,872	Inc. 23,449	3·3
Lead ores .....	161,614	151,660	Dec. 6,954	3·8
Copper ores .....	633,354	717,306	Inc. 83,952	13·3
Gold and silver ores .....	10,845	18,487	Inc. 8,358	77·4
Cobalt, nickel, and bismuth ores .....	5,180	4,087	Dec. 1,093	21·0
Iron pyrites .....	127,036	124,950	Dec. 2,086	1·6

The year was evidently one of great activity, all the important products showing increases of considerable importance. The most valuable of the potash salts reported in 1896 were 174,515 tons of chlorate of potash and 71,958 tons of Glauber salts. The principal iron ore producing districts last year were Elsass-Lothringen, 4,841,633 tons; Luxemburg, 4,758,741 tons; Bonn, 2,680,889 tons; Breslau (Silesia), 529,602 tons.

The output of the metallurgical works is given below, gold and silver in kilos.; all other products in metric tons:—

—	1895.	1896.	Changes.	Per Cent.
Gold .....	Kilos. 3,547	2,187	Dec. 1,050	42·5
Silver .....	301,979	428,429	Inc. 36,450	9·2
Copper .....	25,777	29,319	Inc. 3,542	13·3
Lead .....	114,491	117,722	Inc. 3,231	2·8
Zinc .....	159,286	153,100	Inc. 2,814	1·9
Pig iron .....	5,417,548	6,295,272	Inc. 877,724	16·2
Nickel and bismuth salts .....	1,143	1,391	Inc. 248	21·8
Antimony and manganese .....	989	1,326	Inc. 337	34·0
Arsenic products .....	3,014	2,637	Dec. 377	12·6
Copper sulphate .....	4,638	6,046	Inc. 1,408	30·6
Sulphuric acid .....	537,928	590,888	Inc. 52,960	9·8

Here, again, all the important products show considerable gains in 1896 over the preceding year. Included in nickel and bismuth salts are all products of nickel and bismuth ores, such as oxides, colours and the by-products, uranium salts, &c. Of the lead, 113,792 tons were metallic lead,

3,930 tons litharge and oxides. Of the sulphuric acid, 575,942 tons were ordinary acid, 14,946 tons concentrated acid.

#### PHOSPHORUS FOR AUSTRALIA.

*Chem. and Druggist, May 8, 1897, 731.*

Shippers of phosphorus to Victoria should note that, in the opinion of the Chief Inspector of Explosives of that colony, the zinc drums at present in use are too thin to prevent leakage of the water, and that in consequence there is great risk from fire. Recently a fire through the leakage of a drum was narrowly averted at Melbourne. The inspector thinks the drums should be thicker and painted outside with several coats of white paint. It is thought that the Victorian Customs may soon make drastic regulations regarding the landing and storing of phosphorus.

### BOARD OF TRADE RETURNS

#### SUMMARY OF IMPORTS.

Articles.	Month ending 30th April

Silver ore..... Value £	..	..	94,432	32,272
Tin..... Cwt.	36,518	41,188	109,067	123,255
Zinc..... Tons	5,516	6,262	84,267	109,187
Other articles... Value £	..	..	244,753	190,396
Total value of metals.....	..	..	1,683,325	1,701,612

#### IMPORTS OF CHEMICALS AND DYESTUFFS FOR MONTH ENDING 30TH APRIL.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Alkali..... Cwt.	16,742	11,581	£ 7,873	£ 6,372
Bark (tanners', &c.) .. "	23,285	27,000	8,407	9,032
Brimstone..... "	29,903	29,015	5,063	5,519
Chemicals..... Value £	..	..	98,006	103,439
Cochineal..... Cwt.	143	165	1,128	959
Cutch and gambier Tons	2,823	2,158	64,036	39,440
Dyes:—				
Alizarin..... Value £	..	..	22,412	16,437
Anilin and other..... "	..	..	34,835	39,697
Indigo..... Cwt.	4,827	11,575	70,343	210,746
Nitrate of potash..... "	39,698	35,258	32,837	24,779
Valonia..... Tons	3,319	3,876	33,208	37,880
Other articles... Value £	..	..	159,353	113,929
Total value of chemicals.....	..	..	528,531	608,029

#### IMPORTS OF OILS FOR MONTH ENDING 30TH APRIL.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Cocoa-nut..... Cwt.	14,861	17,802	£ 19,880	£ 18,944
Olive..... Tons	2,408	898	77,521	30,925
Palm..... Cwt.	81,292	63,713	84,345	65,283
Petroleum..... Gall.	14,380,459	12,990,848	288,564	236,680
Seed..... Tons	3,175	2,230	61,308	63,626
Train, &c. .... Tons	1,977	1,005	26,232	19,997
Turpentine..... Cwt.	2,547	12,342	1,984	11,849
Other articles .. Value £	..	..	88,271	75,540
Total value of oils.....	..	..	628,705	522,568

#### EXPORTS OF DRUGS AND CHEMICALS FOR MONTH ENDING 30TH APRIL.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Alkali..... Cwt.	654,000	477,596	£ 111,739	£ 125,849
Bleaching materials..... "	93,619	88,184	31,974	28,076
Chemical manures..... Tons	25,448	34,239	130,649	169,683
Medicines..... Value £	..	..	88,653	91,615
Other articles..... "	..	..	352,241	441,951
Total value.....	..	..	715,256	856,276

EXPORTS OF METALS (OTHER THAN MACHINERY) FOR  
MONTH ENDING 30TH APRIL.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Brass..... Cwt.	9,567	7,771	£ 37,900	£ 35,524
Copper:—				
Unwrought.... "	89,516	28,087	113,372	73,199
Wrought..... "	27,054	24,686	72,279	70,411
Mixed metal.... "	26,945	18,775	50,039	46,108
Hardware..... Val £4	..	..	102,803	185,425
Implement..... "	..	..	108,374	115,332
Iron and steel... Tons	28,033	161,008	1,067,385	2,150,121
Lead..... "	3,002	2,083	33,356	36,861
Plated wires... Value £	..	..	21,215	30,328
Telegraph wires... "	..	..	23,066	75,688
Tin..... Cwt.	9,430	8,928	30,406	27,650
Zinc..... "	18,860	12,092	11,016	9,123
Other metals... Value £	..	..	71,420	77,297
Total value.....	..	..	2,716,535	2,958,212

EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH  
ENDING 30TH APRIL.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Gunpowder..... Lb.	513,440	633,200	£ 13,780	£ 19,596
Military stores... Value £	..	..	120,471	154,840
Candles..... Lb.	1,710,700	1,302,100	26,907	26,354
Caoutchouc..... Value £	..	..	9,234	96,063
Cement..... Tons	30,150	25,008	49,174	41,817
Products of coal Value £	..	..	162,811	179,135
Earthenware... "	..	..	153,420	171,591
Stoneware..... "	..	..	17,825	20,184
Glass:—				
Plate..... Sq. Ft.	167,503	114,296	7,287	7,770
Flint..... Cwt.	6,509	9,934	16,283	19,650
Bottles..... "	64,488	85,338	30,024	49,511
Other kinds.... "	21,900	25,000	16,286	21,052
Leather:—				
Unwrought.... "	9,908	13,325	92,447	117,713
Wrought..... Value £	..	..	27,001	39,487
Sisal..... Tons	5,138	5,614	97,008	92,849
Flourcloth..... Sq. Yds.	1,922,300	2,572,500	79,537	105,435
Painters' material Value £	..	..	139,563	138,322
Paper..... Cwt.	81,136	91,524	129,145	140,297
Rugs..... Tons	4,012	4,432	22,312	25,988
Soap..... Cwt.	54,895	65,989	59,091	70,791
Total value.....	..	..	2,723,558	3,057,121

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### 1.—PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

9315. A. Forrot. An incandescent furnace for heating gas retorts. April 13.

9522. E. Edwards.—From C. Schaaf. Improvements in muffle furnaces. April 14.

9523. A. J. Campbell.—From E. Sterne. Machinery or apparatus for charging metal capsules or containers with highly compressed or liquefied gas, and for closing the same when so charged. April 14.

9524. A. J. Campbell.—From E. Sterne. Improvements in means for closing capsules or containers for liquefied or highly compressed gases. April 14.

9582. S. H. Johnson. Improvements in filter presses. Complete Specification. April 15.

9929. G. Buck and E. Strong Torrey. Improvements in apparatus for carburetting air. Complete Specification. April 20.

9941. J. Klein. Improvement in apparatus for cooling, concentrating, evaporating, and graduating liquids. Complete Specification. April 21.

10,202. C. Humfrey. Improvements in condensers. April 23.

10,867. A. Ehrhardt. Improvements in linoleum drying and oxidising apparatus. Complete Specification. May 1.

10,988. F. J. Collin. Apparatus for cooling and washing gases. May 3.

11,181. E. Makin, jun. Improvements in apparatus for the condensation of steam and other vapours, and the cooling of heated liquids. May 5.

11,225. G. B. Ellis.—From La Société des Usines du Rhone, anciennement G. P. Monnet et Cartier. Improvements in means for closing receptacles for highly volatile liquids and for regulating the discharge therefrom. May 5.

11,450. H. McPhail. An improved method of and means for evaporating or drying viscous substances, semi-liquids, and pasty materials. May 7.

11,451. H. McPhail. An improved method of boiling and evaporating liquids, and of digesting materials in liquids. May 7.

11,542. D. Williams and E. R. Davies. An improved gas, smoke, and foul air extractor. May 10.

11,700. E. Simoneton. Improvements in the process of and apparatus for filtering liquids. Complete Specification. May 11.

11,724. G. Williams and R. J. Waddell. Improvements in evaporators for brine or other solutions. May 11.

11,803. J. Williamson. Improvements in filter presses and similar filtering apparatus. May 12.

11,872. J. Hill. Improvements in filter presses. May 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

8250. T. O'Hara and J. R. and T. Ashmore. Valves. April 21.

9084. J. Longshaw. Vacuum apparatus for drying, distilling, concentrating, and other like purposes, and method and means for obtaining and maintaining vacuum therein. April 21.

10,547. C. H. C. Rudd. Improvements in diaphragm and disc valves for chemical corrosive fluids, gases, &c. May 19.

11,136. E. C. Mills and J. G. Chamberlain. Filters for extracting grease and other impurities from feed water for steam boilers. May 12.

11,633. S. K. Welch. Filtering apparatus. May 5.

12,109. P. Hereng. Carburetting apparatus. May 19.

12,572. S. G. Merrick and H. L. Washburn. Vapour condensers and apparatus for destroying noxious fumes, recovering by-products from distillation, and like purposes. May 5.

14,478. F. Dehaitre. Apparatus for drying and finishing fabrics. May 5.

14,609. M. Stanbrook. Apparatus for cooling air for use in refrigerating. May 12.

14,951. E. J. Duff and J. Brock. Evaporating brine and other solutions, and apparatus therefor. May 5.

14,952. T. Glover and J. Brock. Apparatus for evaporating solutions with multiple effect. May 19.

- 15,797. E. C. Mills. Apparatus for cooling water for condensing and other purposes. May 19.  
 25,643. M. H. Smith. Apparatus for cooling purposes and for diffusing heat. May 12.  
 29,191. J. V. Forns. Improvements in tele thermometers. April 21.

1897.

2900. H. Hirzel. An improved column for condensing, absorbing, heating, distilling, and otherwise treating gases and liquids. April 21.  
 4762. R. Matchett. Apparatus for reducing the pressure of liquids and gases. May 5.  
 6916. P. Jensen.—From G. Lunge and L. Rohrmann. Improvements in Glover towers, Gay-Lussac towers, and the like, used, for instance, in the manufacture of sulphuric, muriatic, and nitric acids. May 5.  
 7127. P. Jensen.—From L. Rohrmann and H. H. Niedenfuhr. Improvements in Glover towers and the like. May 12.

## II.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

9294. A. H. Barthez. An improved portable and automatic apparatus for the production of acetylene gas for lighting purposes. Filed April 12. Date applied for Sept. 22, 1896, being date of application in France.  
 9387. J. A. Sinclair. Improved means for lighting by electricity and incandescence. April 13.  
 9611. S. Straker. Improved apparatus for the production of an explosive gas by carburetting benzoline and other hydrocarbons. April 15.  
 9656. W. A. G. v. Heidenstam. Improvements in or connected with the manufacture of charcoal. April 15.  
 9714. U. Kesselring. An improved apparatus for the manufacture of acetylene gas. Complete Specification. April 15.  
 9762. J. G. A. Kitchen. Improvements in burners for acetylene. April 17.  
 9763. J. G. A. Kitchen. Improvements in or connected with portable generators for producing acetylene from calcium carbide. April 17.  
 9770. J. Walsh. Improvements in gas lighting and in electric lighting for magnifying purposes, and the application of same to lighting in general. April 17.  
 9857. E. K. Hutton and W. Hutton. Acetylene gas generator for lighting cycle and carriage lamps. April 20.  
 9953. C. E. McVilvie and J. Horne. An improved retort to be used in the manufacture of oxygen gas from atmospheric air. April 21.  
 9996. W. Buddens. New or improved process for obtaining thorium oxide and for enriching monazite sands. Complete Specification. April 21.  
 10,103. J. M. M. Rosenberg. Improvements in or relating to apparatus for the production of acetylene gas. April 22.  
 10,186. D. C. Morency. Improvements in apparatus for generating acetylene gas. Complete Specification. April 23.  
 10,199. W. P. Thompson.—From The Deutsche Acetylen-gas Gesellschaft mit beschränkter Haftung. Improvements in apparatus for developing acetylene gas. Complete Specification. April 23.  
 10,249. W. P. Thompson.—From The Deutsche Acetylen-gas Gesellschaft mit beschränkter Haftung. Improvements in or connected with apparatus for the production and consumption of acetylene gas. Complete Specification. April 24.  
 10,320. M. Sheffel. Improvements in the manufacture and production of bodies for use as filaments in electric incandescent lamps, or for making hoods or mantles for incandescent gas lighting, or for like purposes. April 26.

- 10,321. P. Dyckovitz and M. Sheffel. Improvements in the manufacture and production of mantles or hoods and other incandescing bodies for lighting purposes. April 26.  
 10,371. A. A. Stephenson. An improved method and composition for making gas. Complete Specification. April 26.  
 10,423. F. J. Clinch-Jones. Improvements in gas producers. April 27.  
 10,508. E. Evans. Improvements in apparatus for generating acetylene or other gas generated by the addition of a liquid to a solid. April 27.  
 10,686. J. J. Patterson. Improvements in apparatus for generating acetylene. Filed April 29. Date applied for Dec. 22, 1896, being date of application in United States.  
 10,796. H. J. Barbier. Improvements in means for the storage of compressed gas. April 30.  
 10,825. A. S. Bower and G. Bower. See Class X.  
 10,900. H. Hansen. Improvements in the manufacture of fuel blocks from petroleum. May 1.  
 10,941. A. A. Quentin. Improvements in apparatus for carburetting air. May 1.  
 11,010. M. Otto. Improvements in the manufacture or production of ozone and in apparatus therefor. May 3.  
 11,130. A. C. Humphreys and A. G. Glasgow. Improved method and apparatus for making carburetted water-gas. Complete Specification. May 4.  
 11,131. A. C. Humphreys and A. G. Glasgow. Improved process and apparatus for making carburetted water-gas. Complete Specification. May 4.  
 11,210. L. de Proft. A process of treating mantles for incandescent gas lighting to render the same flexible or supple. Filed May 5. Date applied for Oct. 5, 1896, being date of application in Belgium.  
 11,252. F. Van den Abeele. Improved automatic apparatus for supplying incandescent gas-burners with gas under pressure. Complete Specification. May 5.  
 11,644. H. Sathliffe. Improvements in gas generators. May 11.  
 11,739. F. R. Foster. Improvements in incandescent mantles for gas-burners. Complete Specification. May 11.  
 11,838. F. B. Courtenay. Improvements relating to gas-producing apparatus. May 12.  
 11,873. T. Jamieson. Apparatus for generating acetylene gas from a metallic carbide. May 13.  
 12,021. H. Freise. Process for manufacturing a smokeless inflammable wick. Complete Specification. May 14.  
 12,096. L. J. Davies. An improved process for making coke from anthracite and similar coal. Complete Specification. May 15.  
 12,108. Sir C. S. Forbes, Bart. Improved apparatus for vaporising and burning liquid fuel. May 15.  
 12,110. G. Trouvé. Improvements in apparatus for the production and storage of acetylene gas. May 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

8384. B. H. Thwaite. Process and plant for generating combustible gases. April 21.  
 8402. C. D. Jenkins. Preparation of peat for fuel, and apparatus therefor, and for analogous purposes. April 21.  
 9599. R. Bradshaw. Artificial fuels. May 12.  
 9630. C. Coppeaux. Method and means or apparatus for facilitating the combustion of acetylene gas. May 12.  
 10,407. R. Goodwin. A portable lamp standard to produce and burn acetylene gas or acetylene and carbonic acid gas combined. April 21.  
 10,725. G. Webb, jun., and J. W. Kelly. Apparatus for automatically generating gas. April 28.

11,530. The Economical Gas Apparatus Construction Co., Ltd., and L. L. Merrifield. Apparatus for the manufacture of carburetted water-gas. May 5.

11,632. J. E. Goldschmid and C. Dellwik. Manufacture of water-gas. May 5.

11,951. J. Meikle. Treating peat, coal, and other carbonaceous substances for the obtaining of illuminating gas. May 5.

12,047. M. C. A. Fourchotte. Method of and apparatus for generating acetylene gas. April 21.

12,430. A. Arter. Treatment of gas for illuminating and other purposes. May 19.

12,535. O. Inray.—From F. Bruuck and Co. Horizontal coke ovens. May 5.

12,942. T. Thorp and T. G. Marsh. Method and apparatus for treating acetylene prior to combustion. May 19.

13,059. J. E. Duke. Manufacture of mantles or incandescing bodies for incandescent gas lamps. April 28.

11,365. C. Killing. Incandescence bodies for incandescent gas lighting. May 5.

14,345. R. Langhans. Manufacture of incandescing media for use in incandescent gas lighting. May 19.

14,341. H. Strache. The manufacture or preparation of improved odourising substances for artificially imparting odour to gases. May 12.

14,943. H. Strache. Process and apparatus for the removal of sulphuretted hydrogen from gases or gaseous mixtures. May 19.

15,122. F. H. Haviland, A. Holloway, J. B. Collier, and W. H. Murch. Apparatus for generating acetylene gas. April 28.

15,139. G. Isaac. Process for rendering acetylene gas inactive when brought into contact with metals with which it forms explosive compounds. April 21.

#### 1897.

8. T. J. Meek, H. Davison, and J. Southam. An improvement in ascension pipes used in the manufacture of coal-gas. May 19.

885. T. Holliday. Means or apparatus for use in the production, storing, and application of acetylene gas. April 21.

1519. A. Sterza. Apparatus for preparing or rendering acetylene gas fit for heating purposes. May 5.

2194. P. W. von Gehlen. Apparatus for producing and using an incandescent light produced from benzene gas. May 19.

2292. G. de R. de Sales. Apparatus for generating and storing acetylene. May 19.

2976. W. H. Dennis. Acetylene gas lamps and generators. May 12.

5149. A. Roedel. Process and apparatus for removing graphite crusts from the interior of gas retorts. April 21.

5639. J. Kohlendorfer. A process for producing a solid or consistent fuel containing petroleum. April 21.

5758. H. R. Bean and H. Ringwood. An improved automatic generator, condenser, and holder for acetylene and other gases. April 21.

6157. G. Percire, E. Sorel, and B. Cruvellier. Manufacture of acetylene gas and apparatus therefor. May 5.

7744. E. G. Brewer.—From The Gesellschaft für Acetylen-Gaslicht Basel. Apparatus for generating acetylene gas. May 5.

7782. H. H. Lake.—From F. Ferraccin. Apparatus for automatically generating acetylene gas. May 5.

7920. J. B. de Lery. Method and apparatus for effecting illumination partly by flame and partly by incandescence. May 12.

8779. D. Meyer. Incandescent gas burners. May 19.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### APPLICATION.

10,577. G. C. Marks.—From La Compagnie pour la Fabrication des Compteurs et Matériaux d'Usines à Gaz. Triple-action apparatus for the recovery of benzols or other products contained in certain gases. April 28.

#### COMPLETE SPECIFICATION ACCEPTED.

1896.

9914. A. C. Thomson. Vertical retorts for the destructive distillation of carbonaceous substances. April 21.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

9268. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of 1-phenyl 2-alkyl-pyrazolones. April 12.

9702. H. H. Lake.—From K. Oehler and Co. Improvements in the manufacture of colouring matters. April 15.

9710. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of stable diazo-compounds. April 15.

10,208. S. Pitt.—From L. Cassella and Co. Producing black pigment colours. April 24.

10,605. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the manufacture or production of colouring matters. April 28.

10,810. J. Hauff. A process for the preparation of orthotoluolsulpho acid and of ortho sulpho benzoic acid by oxidation of orthothiocresol. Complete Specification. April 30.

11,572. C. Mills, and Brooke, Simpson, and Spiller, Ltd. A method of preparing basic direct cotton dyeing colours of a blue and blue-black shade. May 10.

11,871. J. Owen. An improved liquid black stain for staining and polishing articles of vulcanite. May 13.

11,997. J. Inray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Manufacture of substantive colouring matters. May 14.

11,998. H. Inray.—From Anilinoel Fabrik A. Wagging. Improved manufacture of ammonium salts of casein. May 14.

12,011. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of new alizarine dyestuffs. May 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

9477. L. P. Marchlewski, E. S. Wilson, and E. Stewart. Production of dyes. May 5.

10,904. E. Fischer. Manufacture or preparation of derivatives of xanthine from alkylated uric acids. May 5.

11,370. Read, Holliday, and Sons, Ltd., J. Turner, and J. Turner. Production of colouring matters. April 21.

12,142. S. Pitt.—From L. Cassella and Co. Production of polyazo dye-stuffs. April 21.

12,556. S. Pitt.—From L. Cassella and Co. Production of dye-stuffs suitable for dyeing wool. April 21.

12,922. A. G. Green and A. Wahl. The manufacture and production of new cotton colouring matters. May 12.

14,144. I. Levinstein and Levinstein, Ltd. Azo colouring matters. May 5.

14,563. J. Y. Johnson. From The Badische Anilin and Soda Fabrik. Manufacture and production of mordant-dyeing colouring matters and of intermediate products relating thereto. May 5.

27,775. J. Ville. New red colouring matters of the triphenylmethane series and the method of producing the same. May 12.

1897.

15,755. H. Baum. Manufacture of colouring matter of the rhodamine group. May 5.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

### APPLICATIONS.

9517. R. Thomas and E. Prevost. Improvements in or relating to the process of mercerising vegetable fibres or textile fabrics. Complete Specification. April 14.

10,547. D. McCallum. The reducing of the inflammability of cotton fabrics. April 28.

10,781. H. Imray. From La Société Anonyme des Blanchiments, Teintures, et Impressions. A process for giving lustre to vegetable fibres and textures. April 30.

10,784. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brüning. An improved method of mercerising cotton yarns. April 30.

10,911. W. Scheulen and H. Mann. Improvements in the process of finishing bleached and cleaned textile fabrics, yarns, and woven goods of cotton, wool, and tussah silk. May 1.

11,313. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brüning. Improvements in mercerising vegetable tissues. May 6.

11,801. A. H. Prinz. Improvements in the treatment of jute, bast, china grass, reed, and like plants for use in textile industries. Complete Specification. May 12.

11,826. Count Hilaire de Chardonnet. Improvements in the manufacture of artificial silk. May 12.

11,917. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brüning. A process for chlorination of wool. May 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

12,693. S. Bennett. Treatment of wood, paper, fabrics, fibres, and like materials impervious and inalterable by moisture and climate and other influences. May 19.

13,707. T. E. Briggs and E. Webb. Apparatus for polishing and drying yarns, threads, twines, or cords. April 28.

1897.

3832. R. W. Strehlenert. Method of spinning artificial silk and apparatus therefor. April 21.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

9392. C. E. Gassmann. A new process of fixation of colours basic and phenolic in printing. April 13.

9499. J. Grossmann. A new indigo vat. April 14.

9804. P. Dosne. Process for imitating on vegetable fibres, fabrics woven in colours. April 17.

10,213. E. Bentz. Improvements in the production of white and coloured patterns on aniline black grounds in calico printing. April 24.

10,787. C. D. Abel. From F. Petersen and Co. Process for dyeing fast black. April 30.

10,901. J. Imray. From La Société Anonyme A. Rondillon et Cie. A process for fixing interference colours on paper or other surface. May 1.

10,933. G. Wendler. A new or improved adapted for use in dyeing wool, in bread or pastry, or other purposes. May 3.

11,110. C. W. Fulton. Method of producing pattern upon textile fabrics. May 4.

11,983. C. W. Fulton. Improvements on method of producing patterns on textile fabrics. May 14.

### COMPLETE SPECIFICATION ACCEPTED.

1896.

10,936. A. F. B. Gomes. Bleaching certain vegetable fibres, more especially those of the urtica family. April 21.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

9418. C. M. White. From Smith, Powers, Simson, Gouens, and Co., Ltd. Improvements in the manufacture of chloride of baryta and oxide of iron. April 13.

10,183. G. B. Ellis. From La Société Chimique des Usines du Rhone, anciennement G. P. Mounet et Cartier. Improvements in the manufacture of aldehydo-benzoic acid and intermediate products. April 23.

10,361. C. Masson and C. Tilliere. Improvements in the preparation or manufacture of borax. April 26.

10,400. A. Crosbie. See Class X.

10,501. A. Feldmann. A process for removing carbonic acid and hydrogen sulphide from ammoniacal liquor. Complete Specification. April 27.

10,509. T. T. Sill. See Class X.

11,210. W. Shedlock. Improvements in apparatus for obtaining salt from brine and for similar purposes. May 5.

11,353. J. R. Wyde, J. W. Kyna-ton, and the United Alkali Co., Ltd. Improvements in the manufacture of hydrochloric acid free from arsenic. May 6.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

13,244. A. Crossley and H. A. Allport. Manufacture of ferric oxides. April 21.

13,841. J. Brock and F. Hurter. Recovering sulphur from sulphuretted hydrogen. April 21.

23,245. J. Pattison. Improved ammoniacal compounds. April 28.

1897.

4179. A. J. Boulton. From S. Ganelin and J. Block. Method of making chloride of lead. May 19.

6916. P. Jensen. From G. Lunge and L. Rohrmann. See Class I.

## VIII.—GLASS, POTTERY, AND ENAMELS.

### APPLICATIONS.

9351. H. Emery. Improvements in the form of saggers for potters' use. April 13.

10,430. H. de Wit. Manufacture of enamelled ceramics with a slaggy biscuit covered over with coloured enamels. Complete Specification. April 27.

10,691. P. Delorme, fils. Improvements in the manufacture of hollow castings of glass and the like, and apparatus therefor. Complete Specification. April 29.

11,343. R. F. Ayre and C. Dunnill and Co., Ltd. Improvements in pottery kilns or ovens. May 6.

11,630. C. C. Seibm and O. Lessing. Process for the ceramic production of grinding agents. Complete Specification. May 10.

11,735. G. Tasche and F. Sporer. Improvements in glass cooling or annealing ovens. Complete Specification. May 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 11,522. H. Hayward. System of glazing. April 21.  
 11,823. W. Macrae. Production of decorative stained glass or imitations thereof. April 28.  
 12,400. W. F. Mason. Kilns for bricks, pottery, and the like. May 5.

1897.

- 11,995. T. Pfister and E. Barthels.—From A. Navarin. Process of work. May 5.  
 11,411. T. W. Horn. Window glass. April 21.  
 11,527. C. Paulus and H. Heim. Manufacture of ceramic material machinery or apparatus for the same. April 21.  
 11,579. C. C. Schirm and O. Lessing. Process for producing ceramic masses. May 12.  
 11,044. H. Heckert. Glass hollow-ware. May 12.

### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

#### APPLICATIONS.

9315. C. Richardson. Improvements in asphaltic pavements and the like. Complete Specification. April 12.  
 9316. L. S. Kasson. Apparatus for treating and assembling the ingredients for the manufacture of paving compositions. Complete Specification. April 12.  
 10,317. W. F. Dyson. Improvements in artificial stone. April 26.  
 11,016. Kuma, Ltd.—From P. W. Wierdsma and J. Kuipers. See Class XIII.  
 11,153. J. N. Santha. Improvements in or relating to the preparation of asphalt for pavements and the like. May 4.  
 11,162. J. Davie and J. Baird. Improvements in manufacturing blocks for paving streets, paving footpaths, and for other constructive purposes. May 5.  
 11,403. J. Brock. Improvement in the composition of matter for bricks. May 7.  
 11,425. H. Coward. An improvement in the construction of fire-proof floors. May 13.  
 12,024. J. C. Rombach and E. S. Resticaux. Improvements in cements for resisting the action of acids, acid vapours, and heat. May 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 11,847. J. E. Brindley. Manufacture of tiles and quarries. April 21.  
 12,368. W. Owen. Manufacture of artificial stone, marble, and the like. April 21.  
 12,693. S. Bennett. See Class V.  
 12,880. A. H. van der Vygh, H. van der Vygh, and G. van der Vygh. An improved fire-proof artificial stone. April 21.

1897.

- 11,771. A. H. van der Vygh, H. van der Vygh, and G. van der Vygh. Construction of fire-proof buildings. April 21.  
 11,439. W. S. Wilkinson. Manufacture of paving blocks, tiles, and the like. April 21.

### X.—METALLURGY, MINING, ETC.

#### APPLICATIONS.

9403. G. W. Gesner. A new and useful alloy of iron and hydrogen, termed Gesner metal, and means for producing the same. Complete Specification. April 13.  
 9409. H. R. Angel. Improvements in the treatment and reduction of sulphide ores containing zinc or otherwise. April 13.  
 9717. F. Ellershausen. Improvements in the treatment of complex sulphide ores. April 15.  
 9840. H. H. Eames. Improvements in apparatus for amalgamating and concentrating precious metals. April 20.  
 10,118. A. James. Improvements in the treatment of gold-zinc slimes from the cyanide process. April 23.  
 10,173. C. P. Shrewsbury. Improvements in means or apparatus for recovering gold from the residue resulting from the treating of tailings by the cyanide process. April 23.  
 10,400. A. Crosbie. Improvements in the method of preparing iron oxides from waste acids or pickle from tinning and galvanising works. April 27.  
 10,403. J. Colley. Improvements in linings of metallurgical vessels. April 27.  
 10,459. A. J. Boulton.—From A. Lismann. A new or improved method of coating copper or copper alloys with patina. April 27.  
 10,509. T. T. Sill. Improvements in the manufacture of red oxide from the waste liquors from galvanising works, tin-plate works, wet copper process, or other residual liquors containing iron in the form of chloride. April 27.  
 10,634. H. C. Bull, C. P. Shrewsbury, and F. L. Marshall. A new or improved process for extracting gold and other metals from sea water. April 29.  
 10,715. J. L. Dobell. Improvements in the manufacture of cupels and crucibles to be employed in the refining of metals. April 30.  
 10,721. G. P. Royston. The annealing of cast iron without melting of the same, by heating at that temperature at which the cast iron, when fused, solidifies. April 30.  
 10,785. B. H. Thwaite and H. V. Holden. A process for decarburating steel or other compounds of iron and carbon, and apparatus for that purpose. April 30.  
 10,825. A. S. Bower and G. Bower. A combined process for the protection of iron and steel surfaces from rust, and for the manufacture of combustible gas. May 1.  
 10,829. J. Swinburne. Improvements in treatment of sulphide ores. May 1.  
 11,081. J. M. Spink. Improvements in annealing metals during manufacture, and in the means or apparatus employed therein. May 4.  
 11,151. G. H. Glenkinsop. Improvements in and relating to the roasting and calcining of minerals and the like substances. May 4.  
 11,410. R. S. Lovelace. An improved method of toughening and strengthening metals. May 7.  
 11,518. C. P. Shrewsbury. Improvements in means or apparatus for extracting gold and other metals from solutions containing such metals. May 8.  
 11,692. E. E. von der Linde. Treatment of tin oxide in the form of powder, sludge, or paste for the smelting thereof. Complete Specification. May 10.  
 11,659. W. Blackmore. The treatment of slags containing zinc and silver. May 11.  
 11,695. J. C. Mewburn.—From La Société Anonyme de Commeny-Fourchambault. Improvements in the manufacture of alloys of or containing iron and nickel. May 11.  
 11,996. G. Deer. An improvement in the smelting of copper, and apparatus for that purpose. Complete Specification. May 14.  
 12,074. F. B. Aspinall and E. C. Ekstromer. Improvements in apparatus for extracting gold from its ore. May 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

3051. J. Robertson. Improvements in shaping, forging, drawing, solidifying, and re-rolling metals, and in means and apparatus therefor. May 19.

8054. T. Huntingdon and F. Heberlein. Treatment of sulphide ores of lead, zinc, or antimony, preparatory to smelting the same, and incidentally in obtaining sulphurous acid. April 21.

8882. A. Tracy. Method of combining hard metal and soft metal or other material to form non-slipping and non-extensible floor covering and stair treading. May 5.

9524. J. A. Bruce-Fraser. Process for extracting gold and other metals from their ores, especially applicable to the treatment of refractory ores. May 5.

9656. The Improved Electric Glow Lamp Syndicate, Ltd.—From C. Schwabe. Process for depositing metals on silver coatings. May 12.

11,833. R. A. Hadfield. Method of toughening or softening manganese steel castings. April 21.

12,255. M. B. Zerener. Precipitation of precious metals from their cyanide solutions. April 21.

12,287. W. Van Wart, F. W. Popp, and J. J. Bradley. A certain new or improved metal or admixture of metals. May 19.

12,328. J. C. Bull. Alloys. April 28.

13,111. E. A. G. Street. Manufacture of chromium and similar alloys. May 19.

13,371. O. Frolich. Process for extracting metals from pyritic ore by the treatment of, with chlorine, and for recovering the chlorine employed. April 21.

13,451. L. Pszczolka. Improvements in Bessemer or Thomas process for the treatment of low qualities of crude iron. May 5.

14,006. C. Parzacott. Manufacture of metallic alloy. May 12.

14,622. A. Wolski. Blast furnaces. May 19.

16,756. Elkington and Co., Ltd., and H. T. Fellows. Muffles for annealing metals and for other like purposes. May 12.

1897.

4202. A. F. M. V. Baron. Manufacture of an alloy of copper and iron. May 19.

5926. J. de Moya. Manufacture of steel. May 19.

8873. W. Noad and W. Agate. Improvements in the obtaining of copper from ores and other copper-bearing substances. May 19.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

## APPLICATIONS.

9276. W. Rowbotham. Improvements in primary batteries. April 12.

9317. Sir C. S. Forbes, Bart. Improvements in plates for secondary batteries. April 12.

9456. J. H. McLean and C. D. Burnet. Improvements in secondary batteries. April 13.

9563. H. T. Cheswright. Improvements in or relating to plates for secondary batteries or accumulators. Complete Specification. April 14.

9631. J. Dunn. A new or improved plate for accumulators or electric storage batteries. April 15.

9803. H. E. de Ruz de Lavison. A voltaic battery having its depolarisation effected by heat. April 17.

9913. E. Marekwald. A manufacture of electrodes for electric accumulators. Complete Specification. April 20.

9914. E. Marekwald. A manufacture of electrodes for electric accumulators. Complete Specification. April 20.

10,254. W. A. Boese. An improved process for the manufacture of accumulator plates. Complete Specification. April 21.

10,279. A. E. Ann.—From C. W. Hertel. Improvements in galvanic batteries. April 24.

10,439. C. E. Lee. Improvements in secondary batteries. Complete Specification. April 27.

10,451. F. S. Brown and L. J. Davies. Improvements in separating stable salts by means of diffusion, and generating electricity direct out of chemical energy. April 27.

10,484. J. L. Dobell. Improvements in or connected with electric batteries. April 27.

10,705. L. Epstein. An improvement in plates for secondary voltaic batteries. April 29.

10,719. W. Rowbotham. Improvements in primary batteries. April 30.

10,822. W. Evans and J. W. Smith. Certain improvements in apparatus for the electro-deposition of metals. April 30.

10,872. J. Sime.—From R. J. Browne and J. G. Dobbie. Improvements in and relating to electric batteries. May 1.

11,190. F. M. Lyte. Improvements in the electrolysis of fused zinc chloride. May 5.

11,231. E. Giglio. Improvements in dry batteries. May 5.

11,236. D. Reynolds. An improved process and means for electrically purifying liquids. May 5.

11,402. W. S. Romme. A process of and apparatus for electrically decomposing solid substances. May 7.

11,578. F. J. Gillibrand. Improvements in or relating to carbon plates, rods, or the like for galvanic batteries. May 10.

11,603. E. Riley. An improvement in plates for secondary voltaic batteries. May 10.

11,800. S. de la Precilla. Improvements in and connected with the formation of galvanic batteries. May 12.

11,844. G. C. Allingham and W. Fennell. Improvements in voltaic batteries and electrolytic decomposition cells. May 12.

11,861. O. Lindner. Improvements in or relating to electric accumulators or storage batteries. May 13.

12,028. R. W. Atkinson and S. F. Walker. Sulphuring carbon plates for galvanic batteries. May 15.

12,073. H. W. Headland and Headland's Patent Electric Storage Battery Co., Ltd. Improvements in secondary battery plates and in moulds for making them. May 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

8906. L. B. Atkinson and F. G. Treharne. Generation of electricity. May 19.

11,338. E. A. G. Street. Electrodes for electrolytic purposes. May 19.

13,200. A. G. Stromberg. Charging accumulators. May 5.

16,256. L. M. Bullier. Electric furnaces. May 19.

16,257. L. M. Bullier. Electric furnaces. May 19.

16,852. G. Poore. Electrolysis. May 5.

22,069. D. Young. From La Société Anonyme "Accumulateur Eclair." Electric accumulators or storage batteries. May 19.

25,369A. F. H. Snyder. Improvements relating to the coating or covering of metals and other substances with metals and other materials by the aid of the electric arc. May 5.

1897.

6818. J. Entwisle. From C. T. Barret. Improved storage battery. April 21.

8131. S. V. B. Essick. Primary electric batteries or generators. May 12.

## XII.—FATS, OILS, AND SOAP.

### APPLICATIONS.

9314. F. Rapp-Rosenthal. A process for the production of oil from peat. Complete Specification. April 12.

9529. S. Rosenblum, S. Rileal, and The Commercial Ozone Syndicate, Ltd. Improvements in the oxidising of oils and in apparatus for the purpose. April 14.

9799. R. W. English. An improved method of and apparatus for bleaching linseed oil. April 17.

10,526. J. R. Whiting and W. A. Lawrence. Improvements in the process of and apparatus for deodorising oil. Complete Specification. April 27.

10,576. J. E. Bedford and C. S. Bedford. An improved method for obtaining solid products from linseed oil. April 28.

### COMPLETE SPECIFICATIONS ACCEPTED.

1897.

1335. E. A. Rach. Method of concentrating glycerin. May 19.

1551. J. C. F. Muller. Process and manufacture of a cleaning and caustic agent. May 12.

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

### APPLICATIONS.

9288. G. W. Young. A new or improved waterproofing compound. April 12.

9495. A. G. Hachre. Improvements in the manufacture of plastic materials. April 13.

9423. C. M. White.—From Smith, Powers, Simson, Geigens, and Co., Ltd. Improvements in the manufacture of red oxide of iron. April 13.

9417. J. W. Blake and S. J. Blake. Improvements in compositions or paints for preserving structures. April 13.

9461. E. Hornung and S. Hansel. Improvements in the treatment of india-rubber, gutta-percha, and their compounds. Complete Specification. April 13.

9538. F. King. Improvements in or connected with the manufacture of articles wholly or partly of rubber or other gum and the like dissolved in a solvent. April 14.

9775. J. S. MacArthur. Improvements in making white lead. April 17.

11,016. Kuuna, Ltd.—From P. W. Wierdsma and J. Kuipers. The manufacture of a new or improved substance or product suitable for use as a substitute for vulcanite, hard woods, or other hard materials, or for other uses or purposes for which same may be applicable. May 3.

11,168. E. Garnier and S. J. Prescott. An improvement in india-rubber compounds and in gutta-percha compounds. May 5.

11,500. T. Grantham and J. J. Grantham. A new or improved boot varnish. Complete Specification. May 8.

11,920. E. J. Soutar-Arnold and W. Buines. A method of extraction or production of caoutchouc. May 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

2677. H. Birkbeck.—From P. W. Wierdsma and J. Kuipers. Manufacture of a new or improved substance or product suitable for use as a substitute for vulcanite, hard woods, or other hard materials, or for other uses or purposes for which same may be applicable. May 12.

10,462. A. H. Sandiland. Manufacture of white lead. May 19.

14,267. D. Marcus. Paints and varnishes. April 28.

14,428. H. C. Webster and R. Crawford. Manufacture of white lead. May 19.

14,884. W. Mitchell.—From G. L. Ball. A liquid for removing varnish. April 21.

1897.

7399. E. O. S. Gentile and H. R. Gentile. Manufacture of pigments, printing inks, or paint mixtures. May 12.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### APPLICATIONS.

9969. J. Biddulph and E. A. Haggard.—From R. Acklom. Improvements in or relating to the treatment of hides. April 21.

11,111. E. O. Daniel. Improvements in the preparation for and tanning of hides and skins. Complete Specification. May 4.

11,597. G. Levinstein. Improvements in and relating to the tanning of hides and skins. May 10.

12,018. A. MacFarlane and H. W. Stanbury. Process of treating gelatine for the production of imitations of various other substances. May 14.

12,099. C. S. Dolley. Improvements in processes of tanning. Complete Specification. May 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,420. E. S. Cook. Process for treating raw hide for use in the construction of pneumatic tyres. May 12.

1897.

3073. J. Howden.—From J. Tyciak. Glue compounds, and applying same to barrels and the like. May 5.

## XV.—AGRICULTURE AND MANURES, Etc.

### APPLICATIONS.

9369. A. Gladstone. Improvements in and relating to artificial manures or fertilisers. April 13.

9704. C. H. Thompson. The manufacture of improved fertilised and fertilising materials. Complete Specification. April 15.

10,369. A. Quaet-faslem. Improved method of and process for working and treating nitrate deposits for the extraction of the nitrates therefrom, and apparatus for that purpose. April 26.

### COMPLETE SPECIFICATION ACCEPTED.

1896.

17,883. E. van De Griendt. Treatment of moss-litter manure for obtaining products therefrom. May 12.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

### APPLICATIONS.

9455. W. Feld. Improved process and apparatus for desaccharising molasses by means of barium hydroxy-sulphide and for regaining the by-products. April 13.

10,395. H. W. Airken. Improvements in apparatus for decalcating and purifying saccharine juice or liquid. April 27.

11,842. Z. Lubinski and R. Krajewski. Improvements in and relating to centrifugal machines for use in the manufacture of sugar. Complete Specification. May 12.

**COMPLETE SPECIFICATION ACCEPTED.**

1896.

11,790. G. Ranson. Process for the complete refining of sugar. May 19.

**XVII.—BREWING, WINES, SPIRITS, Etc.****APPLICATIONS.**

10,180. M. van Look. New or improved process for the preparation of mead. Complete Specification. April 23.

10,899. B. Willecox.—From The Actien-Maschinenbau-Anstalt vormals Venuleth and Ellenberger. Improvements in and apparatus for the preparatory treatment of cereals for use in brewing and distilling. May 1.

11,515. J. H. Folkerts. Improvements relating to the production of yeast and to apparatus therefor. May 8.

11,600. A. C. Briet. Improvements in diffusion apparatus for the manufacture of cider. May 10.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

28,713. C. Killing. Process and apparatus for purifying crude alcohol and other alcoholic mixtures. April 28.

1897.

1455. A. Kinder. Malt kilns. May 5.

**XVIII.—FOODS, SANITATION, Etc., AND DISINFECTANTS.****APPLICATIONS.****A.—Foods.**

9911. E. B. Watson. Employment of diastase as a preservative of oily or fatty vegetable food-matter. April 20.

10,871. J. Hogarth. Improvements in and relating to alimentary substance and beverages. May 1.

10,873. W. T. Murray. An improved process of preserving milk. Complete Specification. May 1.

10,926. J. A. Cope. An improved preservative for eggs and other articles of food. May 3.

11,513. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of albuminous products soluble in water from seeds of plants. May 8.

11,629. H. Higgins. An improved method of treating "separated" milk for alimentary purposes. May 10.

**B.—Sanitation.**

9558. R. H. Reeves. Improvements in or relating to the treatment of sewage. April 14.

9858. J. B. Petrie. Improvements in filtering and oxidising sewage and other foul waters after the same may have been treated by precipitants. April 20.

**COMPLETE SPECIFICATIONS ACCEPTED.****A.—Foods.**

1896.

8232. H. Higgins. Preservation of foods and other perishable goods. April 21.

11,878. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of new albuminous compounds. May 12.

1897.

6064. H. Humbser. Process for preserving substances. May 12.

**B.—Sanitation.**

1896.

11,124. A. Angell and F. Candy. Preparations for use as precipitants in the treatment of sewage and other polluted water. May 19.

14,125. A. Angell and F. Candy. Manufacture of materials for use in the filtration and purification of impure water and other liquids. May 19.

1897.

5793. P. Ahmann. Process for rendering drinking water free from germs. May 12.

**XIX.—PAPER, PASTEBOARD, Etc.****COMPLETE SPECIFICATION ACCEPTED.**

1896.

12,693. S. Bennett. See Class V.

**XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.****APPLICATIONS.**

9578. J. Hautfl. A process for the preparation of sulphide of benzoic acid (saccharine). Complete Specification. April 14.

9664. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the production of a pharmaceutical compound. April 15.

9701. E. Dolle. The manufacture of improved preparations of iron for medicinal purposes. Complete Specification. April 15.

9827. F. Valentiner. A process for the production of aromatic fluoro-hydrocarbons in aqueous solution. Complete Specification. April 17.

9898. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of a new chemical compound. April 20.

10,535. J. W. Mackenzie.—From C. Schmid. A new method for producing an artificial scent or musk-like substance. April 27.

10,594. G. B. Ellis.—From La Société Chimique des Usines du Rhone, anciennement G. P. Monnet et Cartier. Improvements in preparations for producing local anaesthesia. April 28.

10,790. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of new pharmaceutical compounds. April 30.

11,228. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering. The production of sterile iodoform. May 6.

11,344. W. L. Wise.—From Knoll and Co. Manufacture of compounds of ichthyol. May 6.

11,596. J. Wetter.—From J. D. Riedel. Process for the manufacture of salicylo-acetic acid. May 10.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

11,458. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of pharmaceutical compounds. April 21.

12,134. W. P. Thompson.—From Ludwig, Sell, and Co. Process for making a compound of good keeping property of salicin, saligenin, glucose, and free hydrochloric acid. April 28.

14,352. O. Imray.—From The Fabriques de Produits Chimiques de Thann et de Mulhouse. Manufacture of artificial musk. May 5.

1897.

6220. J. C. Fell.—From W. J. Matheson and Co., Ltd. Process of producing acetanilid or acetoluids. April 21.

## XXI.—PHOTOGRAPHY.

### APPLICATIONS.

11,133. G. Sella. Improvements in photographic dark backs for successive exposures for the purpose of colour photography. May 4.

11,612. J. Mo'ry. Improvements in or relating to the art of producing photographs in natural colours. May 10.

12,017. J. Wheeler. Improvements in the production of films and in apparatus therefor. May 11.

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.

## COUNCIL FOR YEAR ENDING JULY, 1897.

President: *Dr. Edward Schunck, F.R.S.*

### Vice-Presidents:

<i>Chas. Dreyfus.</i>	<i>Dr. W. Jay Schieffelin.</i>
<i>Dr. A. Dupré, F.R.S.</i>	<i>E. C. C. Stanford.</i>
<i>Prof. A. K. Huntington.</i>	<i>G. N. Stoker.</i>
<i>Boverton Redwood.</i>	<i>Dr. T. E. Thorpe, F.R.S.</i>
<i>Sir H. E. Roscoe, F.R.S.</i>	<i>Prof. W. A. Tilden, F.R.S.</i>
<i>A. Gordon Salamon.</i>	<i>Thomas Tyrer.</i>

### Ordinary Members of Council:

<i>George Beilby.</i>	<i>C. C. Hutchinson.</i>
<i>R. Forbes Carpenter.</i>	<i>Ivan Levinstein.</i>
<i>R. Le Neve Foster.</i>	<i>J. S. McArthur.</i>
<i>Oscar Guttman.</i>	<i>B. E. R. Newlands.</i>
<i>Douglas Herman.</i>	<i>Sir Robert Pullar.</i>
<i>David Howard.</i>	<i>Wm. Thorp, B.Sc.</i>

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

*E. Rider Cook, East London Soapworks, Bow, E.*

### Honorary Foreign Secretary:

*Dr. Ludwig Mond, F.R.S.*

### General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members whose names are placed in italics in the list of Council will retire from their respective offices at the forthcoming Annual General Meeting.

Prof. F. Clowes, D.Sc., has been nominated to the office of President; Dr. Edward Schunck, F.R.S., has been nominated Vice-President under Rule 11; Mr. A. Gordon Salamon and Dr. Wm. Jay Schieffelin have been nominated Vice-Presidents under Rule 24; and Mr. D. Howard, Mr. Ivan Levinstein, and Mr. Wm. Thorp have been nominated Vice-Presidents under Rule 8.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Mr. John Pattinson and Mr. Walter F. Reid have been nominated under Rule 18, and Sir David Gamble, Bart., C.B., and Prof. J. J. Hummel, under Rule 19, to fill four vacancies among the Ordinary Members of Council.

Sales .....	329 7 1		
	940 7 1		
	£ 5,833 13 9		£ 5,833 13 9

There are now the following Investments:—Metropolitan 3 per cent. Consolidated Stock, 4,47*l.* 9s. 2*d.*; North British Railway Company 4 per cent. Consolidated Lien Stock, 813*l.* 10s.; Midland Railway Company 4 per cent. Preference Stock, 460*l.*; Gas Light and Coke Company 6 per cent. Debenture Stock, 300*l.*; Great Eastern Railway Company 4 per cent. Guaranteed Stock, 65*l.*

We have compared the above Statement with the Vouchers, Counterfoils of the Receipts issued, and Books of the Society, and certify it to be correct. The amount of the Metropolitan 3 per cent. Consolidated Stock has been confirmed by the Chief Accountant to the Bank of England. Certificates for the remaining investments have been inspected, and the Bankers have verified the Balances upon the Deposit and Current Accounts.

(Signed) MALL, WILKINS, RANDALL, & Co.,  
Chartered Accountants.

23, St. Swin's Lane, London, E.C.,  
19th March 1897.

A Ballot List and Member's Ticket are enclosed herewith.

The Annual General Meeting will be held in Manchester on the 14th, 15th, 16th, and 17th July next.

For Application Forms for Tickets, which should be sent in at once, see May number of the Journal. The Society's headquarters will be the Chemical Club, Victoria Hotel.

#### JUBILEE HONOUR LIST.

Her Majesty the Queen has been pleased to confer the dignity of a baronetcy on David Gamble, Esq., C.B.

Her Majesty has also been pleased to confer the honour of knighthood on Prof. Wm. Crookes, F.R.S.

Her Majesty has also approved for promotion to the rank of Knight Commander in the Most Honourable Order of the Bath (Civil Division), Edward Frankland, Esq., F.R.S., M.D.

#### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, part of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List	Each copy 10s.
To Subscribers .....	„ 12s. 6d.
To others .....	„ 15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

#### LIST OF MEMBERS ELECTED 28th JUNE 1897.

- Beadle, Alec A., Beadonwell, Belvedere, Kent, Electro Chemist.
- Benfey, Dr. Hans, 123, Plymouth Grove, Manchester, Manufacturing Chemist.
- Duck, Chas. A., The Bethlehem Iron Co., South Bethlehem, Pa., U.S.A., Chief Chemist.
- Enequist, Erik W., 136, Liberty Street, New York, U.S.A., Chemist.
- Granger, Dr. J. Darnell, 2, Burlington Lane, Chiswick, W., Analytical Chemist.
- Hambly, Fred. J., Gordon's College, Aberdeen, N.B., Lecturer on Chemistry.
- Hyde, Benj. T. B., c/o B. F. Babbitt, 82, Washington Street, New York, U.S.A., Soap Manufacturer.
- King, Joshua, Clarewood, Camberley, Surrey, Indian Civil Service (retired).
- Lloyd, Thos. H., The Laboratory, Penygraig, near Pontypridd, Analytical Chemist.
- Motion, Jno., c/o John Ellis and Co., Edgewater, N.J., U.S.A., Oil Refinery Chemist.
- Pellow, Chas. E., Columbia University, New York City, U.S.A., Adjunct Professor of Chemistry.
- Rae, Roderic H., Edison-Swan United Electric Light Works, Ponder's End, N., Engineer.
- Robertson, Jno. R. H., c/o The Darien G.M. Co., Ltd., Messrs. Gabrois and Sons, Cana, *via* Panama, U.S. Columbia, Chemist.
- Tucker, Samuel A., Columbia University, New York City, U.S.A., Tutor in Industrial Chemistry.

#### CHANGES OF ADDRESS.

- Banks, A. J., 1, o Chancery Lane; The Brewery, Blenheim Road, Horsey Rise, N.
- Beruel, L. A., 1, o McCall P.O.; Luling P.O., Louisiana, U.S.A.
- Beveridge, Jas., 1, o Gravesend; Burnside, Wycombe Marsh, High Wycombe, Bucks.
- Bloxam, A. G.; all communications to 16, Bolingbroke Road, West Kensington, W.
- Charlier, A. C. J., 1, o Glasgow; Glenpark House, Eldon Street, Greenock.
- Clayton, R. H., 1, o Manchester; 12, Park Avenue, Southport.
- Clemes, J. H., 1, o Chyan Bay; Vista, Mount Wise, New-quay, Cornwall.
- Cochrane, Jno., 1, o Springfield; Watford Bridge, New Mills, *via* Stockport, Calico Printer.
- Constable, W. H., 1, o Discard; Australian Alum Works, Runcorn.
- Corcoran, Jas., 1, o London; 122, Brook Street, Chester.
- Exley, A., 1, o Meanwood; 13, Woodbine Terrace, Headingley, Leeds.
- Foster, R. Le Neve, 1, o Droydsden; The Firs, Clayton, Manchester.
- Hall, J. W., 1, o Bombay; B. B. & C. I. Railway, Sabarmati, near Ahmedabad, India.
- Heywood, Jos. H., 1, o Manchester Road; 231, Drake Street, Rochdale.
- Hibbert, W., 1, o 14; 101, Goldhurst Terrace, South Hampstead, N.W.
- James, Alf., 1, o Glasgow; MacArthur and James, 56, New Broad Street, London, E.C.
- Kershaw, J. B. C., 1, o Pimlico; 3, Wavertree Road, Streatham Hill, S.W.
- Kitchen, Theo., 1, o Queen Victoria Street; subscriptions to c/o John H. Kitchen, 60, Watling Street, E.C.
- Lucas, B. R., 1, o Sandbach; 3, Dyar Terrace, Wingham, Northwich.
- MacArthur, J. S., 1, o Hope Street; MacArthur and James, 45, Renfield Street, Glasgow.
- McCrae, Dr. Jno., 1, o Birmingham; 7, Kirklee Gardens, Glasgow, W.
- Miller, J. Hopkins, 1, o McAslin Street; 5, Catherine Street, Parliamentary Road, Glasgow.
- Mitchell, C. A., 1, o Chelsea; c/o Beaufoy and Co., South Lambeth Road, S.W.
- Moffat-Johnston, J., 1, o Midealder; 57, Dick Place, Edinburgh.
- Nelson, H. W., 1, o Rue St. Urbain; c/o R. A. Ross, 17, St. John Street, Montreal, P.Q., Canada.
- Ormerod, Jno., 1, o Littleboro'; Woodland Cottage, Heywood, Lancashire.
- O'Sullivan, Jas., 1, o Ashby Road; High Bank, Burton-on-Trent.
- Parker, C. E., 1, o East Orange; 150, Alden Street, Orange, N.J., U.S.A.
- Richardson, D. B., 1, o Streatham; Tiroran, Pennyghael, Isle of Mull, N.B.
- Royal-Dawson, H., 1, o New South Wales; 3, Kenilworth Road, Ealing, W.
- Sims, Thos. H., 1, o Manchester; 61, Earham Road, Northwich.
- Thomson, G. Carruthers, 1, o Hillhead; 1, Thornwood Terrace, Partick, Glasgow.
- Williams, W. J., 1, o Camden; Station F., 2215, Bridge Street, Frankford, Philadelphia, Pa., U.S.A.
- Wingham, A., 1, o London; Livermead House, Torquay.

#### MEMBER OMITTED FROM LIST.

- Vandenbergh, Dr. Frank P., Erie County Bank Building, Buffalo, N.Y., U.S.A., Professor of Chemistry.

## CHANGE OF ADDRESS REQUIRED.

Holland, Jos., 1 to 70, Higher Ardwick, Manchester.

## Deaths.

Harris, Dr. Sydney J., School of Science, Rossington Street, Leeds.

Hart, Peter, Gransmoor Avenue, Fairfield, Manchester. May 30.

## London Section.

THE CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE, W.

*Chairman*: R. Messel.

*Vice-Chairman*: Boyerton Redwood.

*Committee*:

B. Blount.	H. de Moenthal.
C. F. Cross.	B. E. R. Newlands.
W. J. Dibdin.	S. Rideal.
R. J. Friswell.	E. G. Adair Roberts.
S. Hall.	F. Napier Sutton.
B. Howard.	Wm. Thorp.
E. Grant Hooper.	T. Tyrer.

*Hon. Local Secretary*:

John Heron, 110, Fenchurch Street, E.C.

The names in italics are those of Members of Committee who retire at the end of the current session.

The following have been elected to fill the vacancies, and will take office in July next:—*Committee*: E. J. Bevan, Otto Hehner, J. B. Knight, A. R. Linz, and F. B. Power.

SESSION 1896-97.

Meeting held on Monday, June 14th, 1897.

DR. R. MESSEL IN THE CHAIR.

## NOTE ON A POSSIBLE SOURCE OF DANGER OF FIRE DURING THE TRANSPORT OF BARIUM PEROXIDE.

BY A. DUPRÉ, PH.D., F.R.S.

Two years ago I had the honour of bringing to the notice of this Section the danger of fire involved in the transport of sodium peroxide, owing to its violent action on combustible substances in the presence of water. To-day I wish to bring before you a danger of fire which may be involved in the transport of barium peroxide.

A short time ago I was consulted by the Solicitors' Department of the Board of Trade as to the probable cause of a fire which had broken out on board the steamship "Rialto," an iron cargo steamer, which led to the loss of the vessel. On looking over the list of articles comprising the cargo I did not find any materials which were known to be liable to spontaneous ignition.

The cargo consisted chiefly of caustic soda, old rope, soda crystals, firebricks, cement, soda ash, hyposulphite of soda, bleaching powder, and 5 tons 12 cwt. of so-called barium. The vessel left the Tyne on February 21st, and almost at once encountered very bad weather. At 6 a.m., March 2nd, two men went into the tween decks, above the hold in which the fire subsequently broke out, to secure something which had broken loose. They had no naked light and struck no match while they were below, and noticed nothing unusual. At 5 a.m. on March 3rd signs of fire in the fore

part of the ship were noticed, at 9.30 a violent explosion took place, and on March 5th the ship was abandoned. Nearly all the time a heavy gale had been blowing. At first I was inclined to suspect the bleaching powder, as this material had not only been present in several previous cases of fire in which the cause of the outbreak had remained undiscovered, but several accidents ascribed to the action of bleaching powder have been brought to the notice of the Explosives Department of the Home Office, in one of which the coming together of bleaching powder and methylated spirit caused a fire. Careful inquiry, as well as experiments, have, however, led me to the conclusion that, in the present case, at any rate, the bleaching powder had nothing to do with the fire.

I should add that, while convinced that bleaching powder by itself would not be liable to cause a fire, the accident mentioned above shows that there may be danger of its causing fire if it becomes mixed with other substances. In the present case no such substances were present.

My attention was next given to the so-called barium, which, on inquiry, I ascertained to have been barium peroxide. Remembering my former experience with sodium peroxide, I started with some experiments similar to those made in the former case, but soon found that—at any rate, at ordinary temperature—water had no sensible effect on mixtures of barium peroxide with combustible substances. I next subjected such mixtures to percussion and friction, and found that a mixture of wood meal and barium peroxide could be set on fire either when placed on a steel anvil and a steel weight of two pounds allowed to fall upon it from a height of 40 inches, or, when placed on wood, it was struck a glancing blow with a broomstick. To such a blow the mixture proved indeed far more sensitive than any explosive at present licensed, or likely to be licensed. Proceeding with the experiment it was found that in order to cause fire it was not necessary to mix the peroxide and combustible, but that, by merely placing the peroxide on a deal board and striking it a glancing blow with a broomstick the surface of the wood could be set on fire. Finally it was found that on putting some of the peroxide on a piece of wood and drawing another piece of wood rapidly across it under moderate pressure, one stroke was frequently sufficient to set the surface of the wood on fire. With small portions of peroxide the wood takes fire only along the line of friction, and the flame is soon extinguished; when, however, the peroxide is in larger quantity, and particularly when some of it has been rubbed into the grain of wood, the fire not unfrequently assumes considerable proportions, and, under favourable conditions, would undoubtedly spread readily. Here, then, we have a serious danger, not, I believe, previously recognised, involved in the transport of barium peroxide. It is obviously necessary to pack and stow the peroxide in such a manner as to render it practically impossible for it to come into contact with combustible substances under conditions in which it would be liable to friction.

I should add that sodium peroxide is subject to the same danger, but that I have not succeeded, with the primitive tools mentioned, to set fire to wood by using lead peroxide, red lead, or manganese peroxide in place of the barium peroxide.

Since writing the above I have attended the inquiry into the cause of the fire on board the "Rialto," held at Hull from May 27th to June 1st. From what I learned then it is but fair to state at once that it was, in the first place, clearly proved that the barium peroxide on board the vessel, like all the peroxide shipped for export by that firm, was packed in new well-made oak casks, at any rate strong enough to bear all ordinary risks; and in the second place it was by no means clearly established that barium peroxide was stowed in the hold, in which, almost certainly, the fire originated. This particular fire, therefore, cannot be said to have been traced to the presence of the barium peroxide, but, nevertheless, the possibility of a fire originating from the presence of this material amongst a cargo, owing to its extreme sensitiveness to friction on wood, remains of course unaffected.

During the inquiry Dr. Attfield and Prof. Lewes gave evidence on behalf of the manufacturers of the barium

peroxide, with much, though not all, of which I heartily agree. I must, however, take this earliest opportunity of recording my most emphatic dissent from a portion of it. Both these gentlemen stated that, in their opinion, no danger, or, as subsequently somewhat qualified by Dr. Atfield, no practical danger, would arise even should some of the peroxide escape from the casks and become scattered on the deck, between the casks, or between the wood used for dunnage. I am, on the contrary, most strongly of opinion that should any of the peroxide escape from the casks a fire is extremely likely to break out when the vessel is labouring in a gale. As long, however, as the peroxide remains inside the casks it is a perfectly harmless material.

In conclusion I should like to be allowed to make two suggestions. In the first place, this Section might, I think, do a considerable service to the shipping interest of the country by devoting one or two of its meetings to a discussion of the probable cause of fires on board ships and the best means for their prevention. As the causes are frequently due to some chemical action, this Society would be highly competent to undertake such a discussion. In the second place, it seems to me that the way in which expert evidence is dealt with in our law courts and other places is, to say the least, not satisfactory, and I have often thought that if the evidence given could afterwards be discussed by impartial and competent persons much good might be done in checking what I may perhaps call, the exuberance of fancy indulged in by some witnesses. The Society of Chemical Industry is large and powerful enough to undertake such a task without fear of consequences; and I hope my suggestion may be taken into serious consideration.

#### DISCUSSION.

Mr. T. TYRER had had considerable experience with barium peroxide, but had never had or heard of a conflagration caused by this body, and he was by no means clear that the accident which had given rise to Dr. Dupré's paper was due to it. If his opinion had been asked as to the safety of barium peroxide for export, he would have said that it was safer than coals, and, proper conditions being observed, he would even now express the same opinion. Referring to the wider question touched on by the author, and the position which he suggested the Society should take with respect to it, he would point out that the utmost care should be exercised, in any discussion which might consequently arise, not to unduly increase the fears of carriers of chemicals. The keenness of present-day competition with our foreign neighbours was to a great extent due to the fact that foreigners had greater latitude than their British competitors. Chemicals could be shipped from Hamburg without question which in England would not be received without great difficulty or a guarantee of safety; and there was a daily growing indisposition on the part of shippers to accept the word of even experienced manufacturers as to the safety of chemical exports. There was no doubt that this difficulty was increased by the action of insurance companies and Government departments, taken no doubt with the best intentions in the interest of the public.

Dr. J. ATFIELD admitted the correctness of Dr. Dupré's statements and the views he had expressed as to the liability of barium peroxide to promote combustion. So far as he understood the properties of this body and the precautions taken by those who shipped it, he still considered that there was very slight practical danger even if the powder did leak out in transit. Dr. Dupré had performed an experiment in which he used a weapon partly consisting of hard wood which had been a good deal scored at the end. This weapon he had rubbed sharply across a rough piece of wood in such a way that the grains of the two woods were at right angles to each other, the barium peroxide between them being in a very dry condition. He did not think that these conditions would be realised under ordinary circumstances, and even under such conditions he had never himself succeeded—and he questioned whether Dr. Dupré had succeeded—in producing a fairly continuous fire such as would be likely to lead to a conflagration on board ship. In all else that Dr. Dupré had said respecting barium peroxide he entirely concurred. He could not help thinking, however, that the suggestion which the author

had made respecting expert witnesses generally, if acted on, might lead to very voluminous discussions; nevertheless he agreed that much good might result in some cases from turning the Society into a sort of court of appeal with respect to scientific evidence. He was inclined to go even further than Dr. Dupré with respect to regulations for the packing and transmission of dangerous goods, though he would not do anything that should interfere to any considerable extent with trade, especially with a trade which was in the hands of a small number of men who were well acquainted with its collateral relationships. He was of opinion that the present regulations with respect to "dangerous" goods on board ship created more danger than they prevented, and he would urge that there should be either more stringent regulations or none at all. For his own part he would be in favour of an Act, if it were acceptable to manufacturers and ship-owners as well as shippers, under which certain questionable goods should be labelled C, F, E, or D, according as they were combustibles, fire-feeders, explosives, or generally dangerous.

Mr. E. J. MILLARD inquired what the actual temperature was at which ignition of barium peroxide occurred.

Mr. E. J. BRYAN said that he had made some experiments on the ignition of barium peroxide by heating that body in a powdered state, together with disintegrated wood pulp, in a test tube. The mixture, when heated slightly above the boiling point of water, ignited and burned fiercely.

Dr. DUNN, in reply to Mr. Millard's question, said that it was known that wood began to char at about 400° F., and as he could not produce any charring effect in this way it was obvious that the friction produced in his experiment did not reach that point. He would point out to Mr. Tyrer that he had expressly stated in his paper that he did *not* trace the fire referred to to barium peroxide; but that did not do away with the possibility of danger, which he thought he had proved to exist. Whenever proposals were made to deal with public risks, objections were raised such as Mr. Tyrer suggested. In his view, however, no such objection should stand in the way. It was the unknown danger which led to disaster; a known danger could generally be guarded against. He would not be true to the position he held if he failed to state publicly that he considered the matter dealt with in his paper a source of serious danger. The fact that no accident had yet been proved to be due to barium peroxide was not a very powerful argument; for the same thing might have been said some years ago about picric acid, which was manufactured on a large scale for over half a century and was shipped to every part of the world in utter ignorance of its highly explosive character; now, after several very serious accidents, it was known as one of our most powerful explosives. Referring to the remarks which had been made about the regulations under the Explosives Act, he would point out that whereas, in England, the authorities were required to prove their case in an open court of law before they could take any action against manufacturers or shippers, in Germany, where there were fewer regulations, the police had the power to go into a factory and, on their own authority, order goods with which they were dissatisfied to be summarily destroyed. Surely even strict regulations, carefully guarded against abuse, were better than such arbitrary power. When the Explosives Act was first introduced there was a great outcry among the manufacturers that it would ruin the trade. The trade, however, flourished more than ever, and now, he believed, most manufacturers gladly acknowledged the benefits conferred by the Act.

Prof. Atfield was quite mistaken in saying that the friction must be across the grain; he could quite easily set fire to the wood and barium peroxide by friction along the grain. (*Experiment shown.*)

The CHAIRMAN thought that, considering the responsible position he held, Dr. Dupré had by no means overstated his case. On the other hand, it was not surprising that manufacturers, menaced with foreign competition and harassed by legislative restrictions, should make a stand in their own interest. The suggestion made by Dr. Dupré was on all fours with the very first paper read before the Society by himself. He thought it very appropriate that matters which

caused dissension in the commercial world should be discussed impartially by practical members of the Society, and he felt certain that if this course were taken up in the spirit suggested by Dr. Dupré, it would open a great field of usefulness to the Society, and be advantageous both to manufacturers and to the public officials who had to deal with such matters.

### ON THE VALUATION OF COMMERCIAL NITRATE OF SODA.

By DR. H. PAULI.

CONSIDERING the large sums of money spent in the purchase and sale of nitrate of soda, it is unintelligible that an antiquated method for its analysis is still used to a considerable extent. Instead of estimating directly the most important constituent, nitric acid, the impurities, chiefly water and compounds of chlorine (calculated as sodium chloride), insoluble matter, calcium, magnesium, and sulphuric acid, are determined, and their sum subtracted from 100, the resulting difference being regarded as the correct expression for the percentage of sodium nitrate. This is, to say the least of it, a very unreliable process. Chemical industry requires, in these days of competition, exact methods of analysis, and ought only to admit such a method of refraction, or estimation by difference, when direct estimation is quite impossible. The consideration that all the inevitable errors in the other estimations, influence the percentage of sodium nitrate found by difference alone serves to justify this contention. Above all, the presence of potassium nitrate in Chili nitrate of soda, in varying quantities (in one case about 6 per cent. was found), renders it highly desirable that the percentage of nitric acid shall be determined by experiment, and not by such indirect calculation as that just referred to.

If a sample of Chili nitrate of soda contain potassium nitrate, and not sodium nitrate only, as is assumed in the method of difference, it is clear that, corresponding to the higher atomic weight of potassium, proportionately less nitric acid should be found present than the result obtained by difference would indicate. Thus the method of refraction is deceptive, and the loss falls upon the purchaser.

The percentage of potassium ought to be determined directly by repeatedly evaporating a weighed quantity of the nitrate to dryness with concentrated hydrochloric acid, and subsequently precipitating an aliquot part with platinum chloride.

Agreed as to the urgent desirability of abandoning the method of "refraction" in favour of a direct method, the remaining question is, What method is most suitable for the direct estimation of nitric acid?

For very frequent determinations, the use of Lunge's nitrometer for commercial nitrate of soda may be employed, but in this case the apparatus must always be in order, and even then much depends on the individual skill of the worker. The quartz method of Reich is considered more suitable. According to this method, in which the nitrate of soda, first thoroughly dried at 130° C., is heated to dull redness with excess of pure silica in a platinum crucible, the nitric acid is expelled and determined by the loss in weight. We, in the Hoechst laboratory, have found by repeated titrations, before and after equally long heating, that the chlorides present, suffer no appreciable volatilisation. Latterly perchloric acid has been found in nitrate of soda, probably present as potassium perchlorate, and in one case upwards of 6 per cent. Since then we have often determined the perchloric acid quantitatively, and have found sometimes none and sometimes from 0.1 to 1.3 per cent.

It is only necessary to make two chlorine estimations of the same sample of nitrate before heating, and after heating with a little caustic soda, by Volhard's method of titration, and to calculate the difference as perchloric acid, subtracting the loss in weight, due to the evolution of oxygen from the perchlorate, from the loss of weight obtained by heating with quartz. By the present refraction method of analysis all perchlorates are estimated as nitrate of soda.

From the above, it is evident that analytical chemists are quite able to determine the percentage of nitric acid in

commercial nitrate of soda directly and with accuracy in all cases, and they should no longer hesitate to reject the old false method of determination of sodium nitrate by difference as being unworthy of the present state of chemical science.

(Fresenius, in his classical work on Quantitative Analysis, expresses the opinion that Reich's silica method is the simplest for the purpose, besides possessing all the necessary accuracy. We (Meister, Lucius, and Co.) simultaneously employed this method some years ago, in an analytical dispute, for a third party, in which Fresenius and we were referred to as independent experts.)

The presence of potassium nitrate has no influence on the accuracy of the results obtained by the silica method, but the contrary is the case with the indirect method of refraction.

Assuming that we had a nitrate containing 3 per cent. of potassium nitrate, and that 4.3 per cent. of other ordinary impurities had been found, we should obtain the erroneous result of 95.7 per cent. by the indirect method, whilst the correct result of the silica method gives 95.21 per cent. when calculated as sodium nitrate, i.e., almost  $\frac{1}{2}$  per cent. less.

As regards the influence of potassium perchlorate on the correctness of the results in the case of the indirect method, the result obtained is too high by the percentage of perchlorate present, whilst in the case of the direct method the result is too high by the amount of oxygen evolved from the perchlorate on ignition, i.e., a smaller error than that of the indirect method. If 0.4 per cent. of perchlorate of potassium be present, only 0.28 per cent. too much nitrate of soda is found by the silica method, if one does not (as is now always done), subtract the loss in weight due to evolution of oxygen, calculated from the perchlorate estimation, from the total loss in weight, thus excluding the whole error. [In order to prove that the chlorine compound present was perchloric and not chloric acid in combination, we precipitated the chlorides in commercial nitrate of soda with the quantity of silver nitrate calculated from the chlorine titration, added sufficient concentrated sulphuric acid to the filtrate from the silver chloride, and passed sulphuretted hydrogen into the liquid, which was kept as concentrated as possible from the beginning, until all the nitric acid was decomposed. Chloric acid would, in such a case, be reduced to hydrochloric acid, which, after the removal of the excess of sulphuretted hydrogen with ferric sulphate, would give a precipitate of silver chloride on addition of silver nitrate. This, however, was not the case, but the perchloric acid, which is unchanged by sulphuretted hydrogen, gave, after treatment with excess of caustic soda and subsequent ignition, a precipitate of silver chloride with silver solution.]

### DISCUSSION.

Mr. OTTO HEINER said that the name of Dr. Fresenius having been mentioned, he would not like this occasion to pass without expressing his very deep regret at his death, which had occurred a few days ago. Fresenius had always been to him an excellent friend, and it was perhaps only right that he, as his old pupil, should remind his fellow-members of what they owed to his memory, and the immense influence which his work had had upon the progress of manufacturing chemistry. If Fresenius was not associated with any of the great discoveries which had revolutionised physical chemistry during the last and present generation, it was nevertheless true that no name was more of a household word than was his, not only on account of the books he had written, but of the numerous exact and beautiful methods which he had devised, and which were now in daily use, and without which they could hardly conceive the carrying on of ordinary analytical work. Referring to the paper, he could heartily agree with Dr. Pauli. The accepted method of valuing nitrate of soda was simply an anachronism. It might have been justifiable years ago, when methods for the direct determination of nitric acid

presented difficulties, but it seemed to him absurd at the present time to take into account everything else except the very thing which one was searching for. Anachronisms proverbially died hard, and it would be perhaps most fitting that the last nail in the coffin of this particular one should be driven in by the Society of Chemical Industry.

Mr. T. TYLER wished to support Mr. Hehner in his admiration of the work of his old master, the late Prof. Fresenius. With regard to the subject of Dr. Pauli's paper, he could quite agree with Mr. Hehner that it was absurd to call upon people to pay for what they did not get. If manufacturers paid for nitric acid, they should get it. If the nitrate contained impurities which affected its value in nitric acid, a method of analysis should be used which would give the facts. He was speaking with special regard to the use of nitrate of soda in the enormous industry of sulphuric acid manufacture, and, in that light, Dr. Pauli's paper was one of great importance. If the Chairman saw fit to bring the matter before the Council, he would have great pleasure in supporting him.

Mr. J. HUGHES had expected to hear evidence of the existence of dissatisfaction with the present method of valuation of nitrate of soda, but absolutely no figures had been put before them to prove that that was the case. The Permanent Nitrate Committee was known to be an energetic body, and if it were shown that they were giving nitrate of potash under the name of nitrate of soda they would immediately alter their procedure. He had had occasion to examine a great number of samples, and had never had any complaint of the method used, which, though an indirect one, had the advantage of giving the respective proportions of the impurities in the form of chlorides and sulphates of soda, the exact figures for which were of great importance for manufacturing purposes.

Mr. W. CROWDER observed that statements had been made that quantities of iodine were sometimes found in shipments of nitrate of soda, either in the form of iodide of sodium or iodide of potassium, and asked whether this was a fact.

Mr. W. F. REID wished to support the Chairman's suggestion that the subject of the paper should be referred to the Council, with a view to action in the matter being taken. He regarded the Society as an eminently fit and proper body to take such action, as in it both sides were represented. He would like to inquire also whether Dr. Pauli had made experiments with nitrate of soda containing sulphates as impurities. Part of the sulphuric acid would probably be volatilised on heating with silica.

The CHAIRMAN reminded Mr. Hughes that the fact that many papers had already appeared on this subject, and with the same object, might be taken as *prima facie* evidence of the existence of dissatisfaction with the present method of valuation. Something should be done, and he thought the proper course was to ask the Council to appoint a committee to consider the matter in an unbiased manner. If, therefore, he had the consent of the meeting, he would put the matter before the Council in that sense.

The Chairman's motion, seconded by Mr. Tyler, was then put to the meeting, and was carried *nem. con.*

#### SOME RECENT IMPROVEMENTS IN SMOKELESS POWDER COMPOUNDS AND IN PROCESSES OF MANUFACTURE.

BY HUDSON MAXIM.

EXPLOSIVE compounds are burned in two ways: one by combustion from surfaces exposed to a consuming flame, the other by what is called detonation, by which the explosive is consumed nearly simultaneously throughout its mass by a wave action. Combustion from surfaces, requiring an appreciable time for the consumption of the explosive body, adapts it to use as a gunpowder. The detonative form of explosion adapts a compound to disruptive or shattering purposes, and unfits it as a gunpowder. However, the function of an explosive, whether as a combustive or a detonative compound, is very largely determined by its physical condition, temperature, and the conditions of confinement under which it is fired. The

equivalent of these conditions is produced when a sufficiently large quantity is fired, and also by the force and temperature brought to bear upon a less sensitive compound by another and highly detonative explosive.

It is well known that guncotton can be ignited in considerable quantity, and burned quietly away without detonation. Nitroglycerin in small quantities may be burned like an oil, and even fulminate of mercury may be burned in a vacuum without detonation. Nitrocellulose, the most powerful commercial high explosive known, may even be used as a propellant or gunpowder, in small quantities and under light confinement.

Fibrous guncotton, which consists of an infinite number of small tubes, whose walls, although of a dense colloid, are very thin, owes the facility with which it can be detonated to the fine state of division of this colloid. If guncotton be dissolved in acetone, poured on a plate of glass, and dried, it is well known how the hard and horn-like product resists detonative influences. However, if reduced to a fine powder, its susceptibility to detonation is restored, or if redissolved in acetone, and poured into water in a fine stream, a fluffy, fibrous material is formed, resembling very closely the original fibrous guncotton, and which will detonate with equal ease and violence.

As practically all high explosives may, under suitable conditions, be consumed by surface combustion, similarly may all explosives, under suitable conditions, be detonated. The harder and more coherent the body, the less rapidly it will burn by surface combustion, and the more difficult it is of detonation.

However, the hard and dense colloid of guncotton burns much too slowly, and through too small a thickness of material in large guns under service conditions, to yield a sufficient quantity of gases to produce requisite velocities, without such fine granulation as to expose such a large amount of initial burning area as to exceed permissible pressures, thereby preventing the use of full charges. For this reason, no pure guncotton powder, except in the form of the Maxim-Schüpphaus multi-perforated grains, has yet been produced which has been successful in guns of more than 4- or 5-in. calibre. However, for rifles, shot-guns, and small quick-firing guns, very good results have been obtained, although still higher results are readily obtainable in small cannon powders by multi-perforating the grains.

By our system of multi-perforated grains, a pure guncotton powder may be made which will produce exceedingly high ballistics in guns of the largest calibre.

Another method of meeting the difficulty is to add some other substance which will quicken the combustion of the compound, such as nitroglycerin, which softens the guncotton colloid and causes it to burn with much greater rapidity, effecting the consumption through a sufficient thickness of material to permit of such coarse granulation, with such lessened initial combustion area, as to enable the use of full charges. The best representative of such high percentage nitroglycerin powders is British cordite.

Nevertheless, if the cordite compound be made into grains or strips of the proper size and shape, and suitably multi-perforated by our system, its ballistics are correspondingly improved. We have conducted a large number of experiments with this and similar high-percentage nitroglycerin compounds, with the result that the improved ballistics, above the usual form of solid rods, corresponded with and verified our calculations of the advantages of the perforations.

The exceedingly high temperature of the products of combustion of nitroglycerin is an important factor in the production of the ballistics attainable with high-percentage nitroglycerin powders, but the excessive heating and erosive action on the gun of these powders, together with other objections too well-known to require discussion here, makes it preferable to employ a pure guncotton colloid, or one containing a small percentage of nitroglycerin, provided it can be put into such physical shape as to produce equally high ballistic results.

The hard colloid of guncotton is also modified and caused to burn with somewhat greater rapidity, by digesting it with the smallest possible quantity of solvent, to render

it sufficiently plastic to be stuffed through a die or rolled into sheets. The product, although resembling very closely the colloid formed by a complete solution of the guncotton, still is not so glassy and hard, and will burn through a greater thickness under like conditions. There is another method for effecting a similar result by forming a compound consisting of undissolved fibrous trinitrocellulose agglutinated by a colloid made from a more soluble variety of pyroxylin.

A method patented by us for producing a smokeless powder of this character is substantially as follows:—Trinitrocellulose is made into paper or a thin pulp board, which is subjected to a bath made of soluble pyroxylin dissolved in a solvent which is not a solvent of the trinitrocellulose. In other words, the guncotton paper is sized in a colloid bath, which bath may or may not contain nitroglycerin; the excess of the bath being removed, sheets of the material are placed upon one another and pressed together, whereby a body of any desired thickness is built up. The mass is then placed in a suitable die or mould and multi-perforated in a manner explained further on. The hardness and density of the product may be varied within wide limits by varying the consistence of the bath or the amount of size left in the paper, and also by varying the compression. The material may then be cut into strips approximating in length the powder chamber of the gun, or any length desired. Before being perforated, a sheet of unnitrate paper may be affixed to two surfaces of the body, whereby they will be, to a great extent, protected from ignition during the early stages of combustion in the gun, thus causing a greater degree of combustion to take place within the perforations. Or, the body of material may be multi-perforated and dried, and then coated with any suitable substance which will delay ignition of the surface.

There is one thing which we know to a certainty, and that is, that the shape of an explosive grain is not as it should be when it presents the maximum of combustion area to the flame of ignition, and is consumed with a constantly decreasing burning surface. The configuration of the grain should be such as to present an initial area which, with a given density of loading and weight of projectile, shall produce a desired pressure, and burn with such increase of surface and evolution of gases as shall maintain the pressure equally behind the projectile in its flight throughout the entire length of the gun. In other words, the burning surface should be regulated to the demands upon it for the evolution of gases. The control of its combustion is the great desideratum in a gunpowder. The others are smokelessness, stability, minimum effect upon the gun and gunners, and practicality and cost of its manufacture on a large scale.

The old black and brown powders, being but compressed mechanical mixtures, were unsuited to that special form of grain consistent with the production of the highest ballistic results. With the introduction of smokeless powders made of a dense and tenacious colloid of guncotton, or of guncotton and nitroglycerin, it became possible, by a special system of multi-perforations, to produce a grain which will burn in the desired manner, although this result has not been easy of attainment. Trinitrocellulose requires a large quantity of solvent, not only to dissolve it, but even to render it plastic; and rods or grains formed of it are exceedingly difficult to dry without warping and cracking to pieces; and it is difficult to make it take and retain the exact shape of the forming die. Consequently, unless a very large percentage of nitroglycerin be employed, a composition must be produced which allows working in a much drier state than ever heretofore attempted, in order that the plastic mass shall retain the shape given it by the die in all its geometrical details. All this calls for special tools, special processes, and a special compound.

There are two smokeless powder compounds employed by us, the one consisting of a compound of nitroglycerin and mixed guncottons, the other of mixed guncottons without nitroglycerin. The first is made by mixing together, in a kneading machine, at a temperature of about 120° F., 80 lb. of trinitrocellulose of about 13½ per cent. nitrogen, with 8 lb. of gelatin-pyroxilin of 12 per cent. nitrogen (and soluble in nitroglycerin below

100° F.), 12 lb. of nitroglycerin, and 35 lb. of pure anhydrous acetone, adding thereto 1 lb. of pure urea dissolved in pure methyl alcohol. The mixture is worked in the kneading machine for about an hour at a temperature of about 120° F., heated by means of a water-bath. The mealy mass is then passed between cold rolls and formed into rough sheets, which are then converted into smooth sheets by passing between slightly warmed rolls. The proper consistence for the mass is easily recognised by the experienced workman by the sense of touch, but the amount of solvent retained may also be easily ascertained by weighing from time to time. Only from 15 to 20 per cent. of solvent should be retained when the compound is ready for stuffing or moulding into grains.

The smooth sheets are compactly wound about one another to form a roll of the diameter of the press cylinder, the ends preferably being trimmed. The press is kept warm by means of a water jacket, having a temperature of about 120° F. The press filled, the cylinder is preferably exhausted of the air within the spaces unfilled by the powder. This process, though not absolutely essential, is advisable. The mass is then pressed hard against the head to solidify it. The forming die is now affixed, and the compound forced through it at a pressure varying from 3,000 to 4,000 lb. to the square inch, emerging in the shape of multi-perforated cylinders. The smaller the grain, the softer should be the material and the higher the pressure to force it out. The rods are cut into grains about 3 diameters long, and placed on shelves in a drying room. When partially dried, the drying is finished in a vacuum.

Several years of experience have shown that, after this treatment, a certain trace of solvent is retained, but it is a constant for each size of grain, and no further drying or other change whatever takes place under service conditions.

It hardly needs mention that the pyroxylin and nitroglycerin should possess the highest stability, and that all the other materials entering into the composition should be of the highest standards of purity.

The nitroglycerin may be entirely dispensed with, as I have said, and a pure guncotton composition be manufactured after essentially the same method. In this case, we prefer to use about 80 parts trinitrocellulose, and 19½ parts gelatin-pyroxilin, and ½ per cent. urea. Owing to the absence of nitroglycerin, which facilitates the moulding operation, slightly more solvent is left in the material before pressing. As I have said, it is impossible to evaporate the last trace of solvent from the compound, but, as the quantity remains for ever constant, and never escapes, it does no harm.

We placed 100 lb. of this powder in a room heated to a temperature of 125° F. for two weeks, without showing the least loss of weight. Some of this powder was then pulverised and exposed to the same temperature, when the remaining solvent was driven off. Whatever theories and preconceived opinions may be, the true test of a cannon powder is the test of time and exposure under service conditions.

At the Sandy Hook proving grounds, in the United States, a quantity of this powder was thrown loose upon the floor in an open room, and there exposed, for a period of three years, to the heat of summer and the cold of winter. At the same time, an equal quantity was filled into cartridges and kept sealed up for an equal period. Some of the loose powder was then filled into cartridges and fired side by side, in alternating shots, with that which had been kept sealed, with the result that the ballistics of that which had been exposed and that which had been sealed up were identical, proving that the powder had undergone no change whatever.

These powders can be produced on a large scale, speedily, economically, and, as the experience of years has proved, they can be produced of uniform composition. The machinery, tools, and processes have all proved practicable and workable commercially.

In view of the peculiar treatment to which our powder is subjected in the process of manufacture, we prefer to add a small quantity of urea—the ideal substance to counteract any possible slight local decomposition, such as has been quite recently again pointed out by Mr. Guttman

in his able paper on the stability of nitro-compounds (this Journal, 1897, 281).

The peculiar influence of urea is well illustrated by its use in the manufacture of transparent celluloid, such as photographic films, which—in case they are cut from a block of compressed material, and not made by flowing a comparatively thin solution on glass plates, or by an equivalent method—could not be produced without the use of this substance, as the temperature to which it is necessary to subject the material causes such slight decomposition as to discolour the product. Urea counteracts this by neutralising the nitrous acid as fast as formed. Urea has the further advantage above any other neutralising substance, in that it is decomposed by nitrous acid into carbonic acid gas, water, and nitrogen, leaving no solid product in the material, while it is not an active alkali and its presence has no effect whatever upon the nitro-compounds with which it is combined.

When soluble pyroxylin is combined with trinitro-cellulose in suitable proportions, it has the peculiar effect of rendering the compound plastic, and enabling it to be moulded with very much less solvent, under the influence of an elevated temperature. This peculiar effect resembles that produced by camphor combined with celluloid pyroxylin. It furthermore renders the final product more teneous and less likely to crack.

I will now call your attention to our various forms of multi-perforated grains. The figures shown in the drawing are *four times* natural size. Fig. 1 represents a bar or strip of the powder compound transversely perforated with

Fig. 1.

Fig. 2

round holes. Fig. 2 shows the same strip nearly consumed, and illustrates the increased burning area produced by the enlargement of the perforations. It will be observed that at the instant of interjunction of the perforations, there remains a portion of the powder unburned. Figs. 3, 4, 5, 6, 7, and 8 represent strips of powder perforated with

Fig. 3.

Fig. 4

angular holes of such shape, and so arranged with respect to one another, as to effect the complete consumption of the entire body of explosive material simultaneously with the interjunction of the perforations. These rods or strips may be made of any desired length—as, for example, the full length of the powder chamber of the gun.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

The remaining figures represent rods or grains of powder longitudinally perforated with round and with various angular perforations, whereby a similar result is effected as that just explained with reference to the other figures.

Fig. 9, perforated with round holes, leaves a small body of unconsumed material, shown in Fig. 10, representing

Fig. 9.

Fig. 10.

Fig. 11.

the same grain nearly consumed. In the remaining figures the powder grain is wholly consumed simultaneously with

Fig. 12.

Fig. 13.

Fig. 14.

the interjunction of the perforations with one another, illustrated by the nearly consumed grains shown in Figs. 12 and 14.

A peculiarity of smokeless powder in its combustion is that the character or shape of a perforation is maintained. This is due to the more rapid combustion in the corners or angles than upon the surfaces lying farther apart, owing to the closer confinement of the gases there evolved.

I think I was the first to invent a powder grain having angular perforations for producing unequal combustion, whereby complete combustion of the grain is effected simultaneously with the interjunction of the perforations.

Fig. 11 represents a grain which is probably the preferable form of perforation for longitudinally perforated powder. This particular form of grain was independently invented by Mr. Fred. H. McGhaie, of Brooklyn, New York, and by myself.

To verify the claims for the particular form of combustion secured by these methods of perforating the powder, I have samples which I shall be glad to show, at the close of these remarks, to anyone wishing to examine them. They exhibit grains of powder at different stages of consumption, demonstrating that our theories are warranted in practice.

We have conducted a larger number of experiments to prevent or retard ignition of exposed surfaces of grains and strips of powder, in order to confine, as far as practicable, the combustion within the perforations. This may be effected by covering the powder with a layer of unnitrate

paper, coating the powder with varnish, or by denitrating the surface of the material, or by coating the material with a layer of non-explosive celluloid. We have found that that form of coating works best which retards ignition sufficiently to give combustion within the perforations a good start of combustion upon the other surfaces, but which coating will be consumed a little in advance of the interjunction of the perforations.

We are aware that a multi-perforated grain of powder is not novel; but that form of perforated grain whereby the highest ballistic results are secured is novel, and a rod or strip of powder having transverse perforations as an article of manufacture is entirely new.

To produce a grain of powder consisting mainly of gun-cotton which will take and retain the shape given it by the die in all its geometrical details, it must be moulded while in a condition quite hard and stiff, and should be worked at an elevated temperature so as to rapidly stiffen by lowering the temperature as soon as formed. When making longitudinally perforated grains, the perforations must be small and the mandrels of the die to produce them must be light and slender, and to prevent distortion they must lie exactly in the path of flow of the material, and the material must therefore be made to pass through spaces between the mandrels at their base. This calls for dies of special construction.

For a fuller description of the processes and apparatus employed by us, mentioned in this paper, I beg to refer you to the following British patents of Dr. Robert C. Schüpphaus and myself:—

No. 22,382 of 1893 (this Journal, 1894, 174); No. 18,682 of 1894 (*ibid.*, 1894, 1219); No. 18,683 of 1894 (*ibid.*, 1894, 1220); No. 8569 of 1895 (*ibid.*, 1895, 820); No. 11,299 of 1895 (not published); No. 11,311 of 1895 (this Journal, 1897, 65); No. 16,861 of 1895 (*ibid.*, 1896, 51); No. 16,862 of 1895 (*ibid.*, 1897, 161); No. 3002 of 1897 and No. 7178 of 1897 (not published).

#### DISCUSSION.

Mr. W. F. REID said there were a few theoretical points upon which he would like to have further information, for example, Was it found that the perforated pellets showed any tendency to break up in the barrel of the gun? Such pellets of black powder had been used, but it was generally found that they broke down under the enormous strain of the explosion. If the prisms failed to retain their form under all circumstances, the disadvantage of an irregular increase of surface would naturally result. The amount of surface exposed to ignition in the first instance was not the only means of modifying the explosive force; but he had heard nothing from the author of other means to that end, such as a difference in the density of the grain, rendering it more easily inflammable on the outside and harder towards the centre or *vice versa*. He had adopted that method himself in the case of the E.C. powder, and found it successful. He agreed with the principle advanced by the author, that gas pressures should not be greater as they advanced towards the muzzle. The experiments made in the United States seemed to prove that one could subject the powder to very varying conditions, and the solvent remained at a fixed percentage. But under service conditions in this country it was found that the varying proportion of the remaining solvent was a serious difficulty. Whether that solvent took part in the explosive action was a very material point in the problem. It must be recollected that explosives manufactured for the English Government had to meet the conditions of various climates, some of them very humid, and therefore the presence of a solvent that might evaporate at different temperatures might have a very serious effect on the ballistics of a powder.

Mr. W. MACNAB observed that Mr. Maxwell Lyte had about 1868-69 introduced a smokeless powder in France which closely resembled the form described by Mr. Maxim.

Dr. A. DUPRÉ had listened with great interest to the paper, which showed a large amount of mechanical ingenuity. There was, however, one chemical point dealt with, *viz.*,

the use of urea. That was a practice which he had always set his face against; it was equivalent to adding, say, horacic acid to milk in order to mask want of cleanliness or of honesty in the milk trade. If a powder were well manufactured it ought to stand without urea or any other masking body. The remarks about making a powder so that it should keep up the same pressure up to the muzzle sounded very well, but practically the idea was an impossible one, for guns could not be made so as to stand such a pressure throughout their length. The pressure should reach its maximum in the chamber, and so give a greater ratio of power for a given weight of explosive. If the guns were as strong at the muzzle as they were at the breech they would be clumsy and unwieldy. Mr. Reid had, if he would allow him to say so, put the cart before the horse. Mr. Maxim, it appeared to him, wanted to produce a powder that burnt more rapidly as combustion proceeded; Mr. Reid desired the reverse. The greater the pressure the more rapid was the combustion, and no peculiar shape of the pellet was needed to ensure this. It was practically impossible to make a powder so that it should just have burned completely as the projectile reached the muzzle and keep up a uniform pressure as well. One might get a greater effect from such a powder, but it would be at the expense of very costly material; and under present circumstances the question of expense was a very important factor.

Mr. HENSON MAXIM, in reply, said that smokeless powder was entirely different in this respect to the old black and brown prismatic powders; but even in smokeless powder, if the rods were long and longitudinally perforated, they would be useless, as they would burst in the centre. They were therefore, when perforated lengthwise, made in comparatively short lengths of about three diameters, and when made in long strips they were pierced with transverse perforations of such a length as not to lead to disruption of the material. With regard to rapidity of combustion, the problem was to perforate in such a way as to produce a pressure as nearly as possible uniform up to the muzzle. Other patents were mentioned in the paper, but as the paper had not been read in its entirety they were passed over. He intended to refer only to his own firm's recent improvements; those of others which were already published could hardly be considered new, and if they were not published, he, of course, could not refer to them. With respect to the production of smokeless powder, it should be made with as little solvent as possible and moulded into grains at an elevated temperature, so as to harden by the lowering of the temperature as soon as formed. If not, it would collapse, shrink, and ultimately crack to pieces. They, by the use of gelatin pyroxylin and trinitrocellulose in certain proportions, worked at an elevated temperature, used but little solvent, and thereby overcame these difficulties. He did not claim the pyroxylin paper as an invention, though the patent covered improvements in treating it, building up and covering it. One of his brother's early patents mentioned the making of gun-cotton into paper, but it was not claimed for lack of novelty. Dr. Dupré had referred to the disadvantages of foreign matter in a powder. For his own part, he did not know of any powder that was free from it. His own firm added about 1 per cent. of urea for safety's sake; if the materials were pure it did no harm, and if the materials should happen to be impure it made the powder stable. The Government put in 5 per cent. of vaselin—a paraffin which had no action on the other ingredients. He must take decided exception to Dr. Dupré's conclusions with regard to the advantages of a powder made to burn with increasing rapidity with consequent maintenance of pressure behind the projectile to the muzzle of the gun. Such a powder certainly had great advantages above one which burnt with a constantly decreasing rapidity. Captain Stewart, of the United States Army, in reporting to the Chief of Ordnance on the Maxim-Schüpphaus powder, said that in this multi-perforated powder the dream of artillery had been realised. He thought Dr. Dupré had misunderstood Mr. Reid, for there could be no advantage in a powder which would burn more rapidly at first and then more slowly. Any of the present multi-perforated powders burnt more slowly as the pressure fell off in the gun, as all powders burnt with a rapidity in

proportion to the pressure. He could see no disadvantage in maintaining the pressure right up to the end, since with a less initial pressure one got as high a velocity. In the trials by the United States Government, they had obtained a muzzle velocity as high as 2,800 feet per second in a 45-pounder gun, 37 calibres long, with less than 35,000 lb. per sq. in. pressure. Unless one used a nitro-glycerin compound or added some oxygen-bearing salt which produced smoke, one must multi-perforate the powder; otherwise it had to be granulated too finely, and full charges could not be employed without too high pressures.

# COMPARATIVE EXPERIMENTS ON THE ESTIMATION OF PHOSPHORIC ACID.

BY ALEXANDER CAMERON, F.C.S.

I HAVE carried out a number of experiments with the view of ascertaining the extent of the discrepancy between the two principal methods of determining phosphoric acid, *viz.*, the molybdate and the citrate methods, and between certain modifications of them. These methods are sketched with some detail at the end of the paper.

The basis of the experiments was tribasic phosphate of lime prepared by adding to a solution of phosphate of ammonia a solution of calcium chloride, the salts being present in their combining proportions. After thorough washing, the precipitated phosphate was dissolved in hydrochloric acid and reprecipitated by the addition of ammonia in slight excess. This precipitate was again filtered, thoroughly washed, dried, separated from the filter paper, and gently ignited. The purity of this phosphate of lime was established by a careful determination of the lime contained in it, it being useless to determine the phosphoric acid present, as the method of estimating that substance was itself under consideration. The estimation of lime was done by precipitating the calcium as calcium oxalate, collecting it on a weighed filter, drying, and weighing as  $\text{CaC}_2\text{O}_4 + \text{H}_2\text{O}$ . Calculating to  $\text{CaO}$ , in two determinations 53.94 per cent. and 51.03 per cent., or an average of 53.99 per cent., was obtained. In other words, about 99.6 per cent. of the  $\text{CaO}$  contained in the phosphate, reckoned as  $\text{Ca}_3\text{P}_2\text{O}_8$ , was recovered; the theoretical amount

of lime, as  $\text{CaO}$ , contained in  $\text{Ca}_3\text{P}_2\text{O}_8$ , being 54.19 per cent. Now it has been proved when estimating the lime in pure calcium carbonate by the above method of weighing as oxalate, that about 99.5 per cent. of the theoretical quantity of  $\text{CaO}$  is obtained, which is almost identically proportional to the results obtained in the phosphate of lime here prepared. There is every reason therefore for believing that the calcium phosphate operated upon is pure tribasic phosphate of lime, as represented by the formula  $\text{Ca}_3\text{P}_2\text{O}_8$ , and the following experiments were based on the purity of this compound. The experiments were also conducted on different samples of superphosphate of lime and mineral phosphates as representing artificial manures. The  $\text{Ca}_3\text{P}_2\text{O}_8$  reported is calculated from the  $\text{P}_2\text{O}_5$  soluble in water in the case of the superphosphates, and from the total  $\text{P}_2\text{O}_5$  in the case of the other materials.

## Estimation by the Citrate Method.

(a.) *The Effect of the Addition of Varying Amounts of Citric Acid:—*

In pure  $\text{Ca}_3\text{P}_2\text{O}_8$ , 0.5-grm. sample.

Citric acid added.....	Grm.	0.25	0.50	1.00
$\text{Ca}_3\text{P}_2\text{O}_8$ recovered.....	Per cent.	97.82	97.12	96.56

In superphosphate of lime, 1-grm. sample.

Citric acid added.....	Grm.	0.50	1.00	2.00
$\text{Ca}_3\text{P}_2\text{O}_8$ recovered, Sample A.	Per cent.	25.06	24.71	24.64
$\text{Ca}_3\text{P}_2\text{O}_8$ recovered, Sample B.	Per cent.	24.58	24.49	24.49

These results show that the larger the excess of citric acid employed, the smaller is the weight of the precipitate obtained. I am always in the habit of weighing out the quantity of citric acid added, having determined, by previous experiment, what the average minimum quantity is, that is required for the various classes of substances.

On a system suggested by Mr. F. J. Lloyd, and on figures with which I have been supplied, I have drawn out the following table, the adoption of which I recommend. The list may of course be indefinitely extended on the same lines:—

TABLE OF PHOSPHATE FACTORS.

Name of Phosphate.	Composition per Cent.			Amount of Reagents when using 2 grms. of Sample.		
	$\text{P}_2\text{O}_5$	$\text{CaO}$	$\text{Fe}_2\text{O}_3 + \text{Al}_2\text{O}_3$	Mz Mixture.*	Am. Ox.	Citric Acid.
					Grm.	Grm.
Algerian .....	25.03	51.99	0.55	} 25	3.0	0.3

" Peace River.....	27.69	41.36	2.49			

\* For composition, see end of paper.

(b.) *The Effect of Iron.*—The larger the amount of iron present the more phosphoric acid will be carried down as phosphate of iron (and alumina, if that substance be present) in the lime precipitates. In the pure salt the amount of phosphoric acid found in the lime precipitates was usually but little over 0.1 per cent., while the addition of 3, 6, and 9 per cent. of ferric oxide to a similar sample

yielded 0.5, 0.6, and 0.7 per cent. respectively of phosphoric acid in the lime precipitates; hence the necessity of determining the amount of phosphoric acid thus carried down. One-third the weight of such precipitates equals the phosphoric acid present. This I have frequently shown to be the case, as the following results, which are the averages of many closely agreeing experiments, prove.

	In Pure Salt.	In Super-phosphate.	In Belgian Phosphate.
Phosphate precipitate, . . . .	Per Cent.	Per Cent.	Per Cent.
$P_2O_5$ , as one-third of precipitate.	0.12	0.10	1.03
	0.11	0.03	0.31
$P_2O_5$ , by actual determination.	0.11	Trace.	0.32

The addition of 3 per cent. of ferric oxide, other conditions being similar, had no effect on the amount of phosphoric acid obtained by the citrate method, while the addition of 6 and 9 per cent. increased the weight of the total  $Mg_3P_2O_7$  precipitate slightly, the results being in the proportion of 100 : 100.39 : 100.79, respectively.

It can safely be concluded that, except in the presence of large amounts of iron (when the molybdate-citrate method should be employed, as described later), the determination of phosphoric acid by the citrate method can be accurately performed.

(c.) *The Volume of Solution before Precipitation.*—This consideration is also very important. As a rule, it may be laid down that the greater the volume of the liquid the less will the precipitate recovered weigh. After separation of the lime the liquid should bulk 200 c.c. as nearly as possible in a 250-c.c. beaker. This figure is easily kept constant by the use of a certain sized beaker, the capacity of which is known to be 200 c.c. at a certain point. Experiments have proved that the loss due to diluting the solution to double the volume recommended amounts to 2½ per cent. of the total as nearly as possible.

(d.) *The Influence of Time.*—Sometimes when phosphoric acid determinations are asked for immediately, the time usually allowed for settling the precipitates obtained with magnesia mixture is a severe tax on the patience of the operator. On several occasions the effect of rapid determinations was tried, the soluble phosphoric acid being reported in about 1½ hours after the commencement of the estimation. The results came out very close to what was obtained in a similar determination conducted by the usual longer method of allowing the precipitate about six hours to settle out. In the short method the magnesia mixture was slowly run in, and the whole stirred constantly for about ten minutes, and then filtered. The filtrates, on being allowed to stand, showed in some cases no further precipitate, while in others a very slight trace came down, equal to about 1 mgrm., when about 2 grms. of the sample were operated upon. Therefore, if the short method is adopted, and 1 mgrm. is added to the weight of the precipitate obtained, the result will be quite accurate.

#### *Estimation by the Molybdate Method.*

When the yellow phospho-molybdate precipitate was dissolved in ammonia and the phosphoric acid reprecipitated by the addition of magnesia mixture, without the addition of any other reagent, high results were obtained in the case of the pure salt, the results being 101.51 per cent., and 101.38 per cent. of  $Ca_3P_2O_8$  in two determinations, or an average of 101.45 per cent. In these determinations the precipitates were not blow-piped, but ignited over a good Bunsen flame for about half a minute after the glow had passed over the surface, the primary part of the ignition being performed over an Argand burner.

Blow-piping the precipitate till constant in weight is commonly adopted, and, if this is done, the results obtained will be low. My experiments on artificial manures confirm the method of correction as recommended by Neubauer (this Journal, 1894, 1092), but as the results obtained by the molybdate-citrate method described below, without blow-piping, are practically the same as those obtained after blow-piping and making the correction, I can see no reason why the blow-pipe should be applied at all.

#### *Estimation by the Molybdate-Citrate Method.*

After precipitating with molybdate solution in the usual manner, filtering, washing, and dissolving the precipitate in ammonia, 0.1 gm. of citric acid is added to the

ammoniacal solution, and dissolved in it before adding excess of magnesia mixture. This is what is termed here the molybdate-citrate method. Duplicate results by this method on the pure salt yielded 99.70 and 99.83 per cent. of  $Ca_3P_2O_8$ , or an average of 99.76 per cent.

In these determinations, as in those by the citrate and molybdate methods, and indeed in all comparative experiments on any substance, exactly the same amount of magnesia mixture was added, and in the same manner, so that no error could accrue from this source.

Excess of citric acid is to be avoided, as tending to give low results. It has been recommended that citric acid be added till the cloudiness, often noticeable in the ammoniacal solution of the phospho-molybdate precipitate, disappears. As a large quantity is often required for this purpose, the results so obtained will certainly be too low. 0.1 gm. has been found to be the best amount to add, provided the phospho-molybdate precipitate has been properly brought down.

#### *Different Methods of Extracting Soluble Phosphoric Acid, with Various Methods of Precipitation compared.*

*1st Method.*—This method consists in taking about 2 grms. of the sample, rubbing it up thoroughly in a tall 100-c.c. beaker with about 20 c.c. to 30 c.c. of cold water on two successive occasions, the solid matter being allowed to settle out each time, after which the clear supernatant liquid is filtered off. The third and final extraction is performed by adding a similar amount of hot water, heating to boiling, allowing the insoluble matter to settle for a moment, and then filtering, the residue being washed on the filter with hot water.

*2nd Method.*—To determine the effect of the washing with hot water in the first method, experiments were now conducted exactly as before and in exactly the same time, the tests being done side by side, cold water, however, in this case being used throughout.

*3rd Method.*—This consists in taking about 7 grms. of the sample, rubbing up thoroughly with about 100 c.c. to 150 c.c. of cold water in a beaker or test glass, allowing to settle over night, filtering, washing with cold water, and making up the filtrate to 500 c.c., 50 c.c. of the resulting solution being taken for the determination. In this case the estimation was done by the citrate method, as in the first two cases.

*4th Method.*—The ordinary molybdate method was used in this case, taking 50 c.c. of the solution prepared for the third method.

*5th Method.*—The molybdate-citrate method. This was conducted exactly in the same manner as the fourth method, adding, however, 0.1 gm. of citric acid to the ammoniacal solution of the phospho-molybdate precipitate before precipitating with magnesia mixture.

*6th Method.*—Re-precipitation. This method was conducted in the same manner as the fourth; the magnesium ammonium phosphate precipitate, however, was dissolved in dilute nitric acid and reprecipitated with excess of ammonia.

The results obtained on different samples of super-phosphate may be seen on reference to the accompanying table.

The difference between the results of the first and second methods in Table A. is not great, but when we compare the third with the first method the difference is apparent, both cold methods failing to give so thorough an extraction of the phosphoric acid as the hot method.

When the molybdate method, No. 4, is compared with the first (the hot extraction) method a considerable difference is found, the molybdate method being the higher of the two. By adding a little citric acid to the ammoniacal solution of the phospho-molybdate precipitate—the fifth method—a slightly lower result is obtained than if no citric acid had been added, while the sixth method (re-precipitating the magnesium ammonium phosphate precipitate) seems to give irregular and undoubtedly low results.

These remarks apply to Table A. Table B. shows the comparative values of the citrate and molybdate-citrate methods applied to the estimation of the total phosphoric acid in rock phosphates.

TABLE A.—COMPARISON OF RESULTS.

Percentage of  $\text{Ca}_3\text{P}_2\text{O}_8$  calculated from the Soluble Phosphates in Superphosphates.

Description of Method.	Method No.	Sample No. 1.	Sample No. 2.	Sample No. 3.	Sample No. 4.	Sample No. 5.	Sample No. 6.	Sample No. 7.	Sample No. 8.	Sample No. 9.

Molybdate-citrate method, in solution of "3." ..	5	..	..	..	25.85	25.34	24.45	33.92	..	27.33
Molybdate reprecipitation method, in solution of "3." ..	6	..	..	..	25.04	24.45	24.64	33.16	..	26.52

\* This addition is referred to later on.

TABLE B.

Percentage of Total  $\text{Ca}_3\text{P}_2\text{O}_8$  in Rock Phosphates, calculated from the  $\text{Mg}_2\text{P}_2\text{O}_7$  Precipitates.

Method.	Belgian.	Spanish.	Aruba.
	Sample No. 10.	Sample No. 11.	Sample No. 12.
Citrate.....	41.82*	41.57*	61.13*
" + $\frac{3}{10}$ .....	(41.63)	(42.40)	(62.41)
Molybdate-citrate.....	41.63	42.46	62.43

\* These results include the phosphoric acid obtained from the lime precipitates.

The Comparative Values.—So many different results being obtained by so many different processes, one is naturally led to inquire which of these methods of extraction and determination approaches most nearly the truth. In order to discuss this question, reference must be made to the results already described, obtained on the pure calcium phosphate. In this salt the  $\text{Ca}_3\text{P}_2\text{O}_8$  found by the ordinary molybdate method averaged 101.45 per cent., while, by using the citrate modification of this molybdate process, an average of 99.76 per cent. was obtained, while again in the citrate method 97.82 per cent. was more than once obtained when only a small excess of citric acid was added. Thus:—

TABLE C.

 $\text{Ca}_3\text{P}_2\text{O}_8$  per Cent obtained in Pure Salt.

Citrate method (same as method No. 1).....	97.8
Ordinary molybdate method (same as method No. 4).....	101.45
Molybdate-citrate method (same as method No. 5).....	99.76

Now, if the results obtained by the molybdate-citrate method be taken as the standard of accuracy, seeing that the results obtained are nearest 100.00 per cent., and if the results obtained by the same method in the samples of superphosphate be also taken as correct, and as equal to 99.76 per cent. of the total  $\text{Ca}_3\text{P}_2\text{O}_8$ , let the other results obtained on the superphosphates be calculated, for the sake of comparison, in proportion, and they will appear as follows:—

TABLE D.

 $\text{Ca}_3\text{P}_2\text{O}_8$  in Samples of Superphosphate, calculated on the Basis of the Molybdate-Citrate Results.

Method.	Sample No. 4.	Sample No. 5.	Sample No. 6.	Sample No. 7.
Citrate (No. 3).....	96.63	97.87	96.91	96.94
Molybdate.....	101.28	102.16	101.01	100.34
Molybdate-citrate.....	99.76	99.76	99.76	99.76

The citrate method (No. 3) already referred to is selected here, seeing that the solution employed in this is the same

as that used for the two following cases, and therefore strictly comparable.

TABLE E.

Percentage of  $\text{Ca}_3\text{P}_2\text{O}_8$  in Samples of Rock Phosphates calculated on the Basis of the Molybdate-Citrate Results.

Method.	Sample No. 10.	Sample No. 11.	Sample No. 12.	Sample No. 13.
Citrate.....	97.82	97.97	97.78	97.89
Molybdate-citrate.....	99.76	99.76	99.76	99.76

Taking the average, the results are, including those on the pure salt:—

Average of  $\text{Ca}_3\text{P}_2\text{O}_8$  per Cent.

Method.	Pure $\text{Ca}_3\text{P}_2\text{O}_8$ .	Superphosphates.	Rock Phosphates.
Citrate (No. 3).....	97.82	97.99	97.79
Molybdate.....	101.45	101.20	..
Molybdate-citrate.....	99.76	99.76	99.76

It will be seen that these average results on the superphosphates and rock phosphates vary in proportion, and are very similar to the results found in the pure salt; and the same conclusion may be arrived at here as in the case of the results there obtained, *viz.*, that the citrate modification of the molybdate process appears to give the truest results, and should be applied to all determinations of phosphoric acid where the greatest accuracy is required.

However, as the citrate method is much quicker and more economical than the molybdate modification, it commends itself in many cases. Nor need the difference pointed out in the average results above be so great if the *hot* method of extraction be adopted, the average result in samples No. 4 to No. 7 in the table being:—

	$\text{Ca}_3\text{P}_2\text{O}_8$ average per Cent. from Table A.
Citrate method, hot extraction.....	26.84
" " + $\frac{1}{10}$ .....	(27.38)
Molybdate-citrate method.....	27.39

Or, calculating the results by the molybdate-citrate method as equal to 99.76 per cent., as found in the pure salt:—

	$\text{Ca}_3\text{P}_2\text{O}_8$ per Cent.
Citrate method, hot extraction.....	97.76
" " + $\frac{1}{10}$ .....	(99.72)
Molybdate-citrate method.....	99.76

Thus it will be seen that the results on the superphosphate of lime are in exactly the same ratio to one another as those in the pure salt (Table C.), and therefore the inference based on one may be equally applied to the other.

Frequently a correction is made for the deficiency resulting from the use of the citrate method. While some recommend an addition of as much as 0.3 per cent. to the amount found, others state that no correction is required.

Now it will be seen, on reference to the above results, that if one-fiftieth of the phosphoric acid, or its equivalent of phosphate of lime ( $\text{Ca}_3\text{P}_2\text{O}_8$ ), be added to the results found, the same result will be obtained, on an average, as found by the molybdate citrate method. The author therefore recommends that if the citrate method be adopted, the addition of one-fiftieth of the percentage of phosphoric acid or phosphate of lime should be made to the result actually obtained by calculation from the weight of the precipitate, and the results taken as accurate. This method of correction, provided the conditions are adhered to, will be found much more convenient than taking into account considerations recommended by other writers. Thus, for example, if 25 per cent. of phosphate of lime be found by actual determination by the citrate method, 25.5 per cent. would be reported as present; and, if 50 per cent. be found, 51.0 per cent. of phosphate of lime would be reported.

This correction does not of course hold good if an excessive amount of citric acid be used in the citrate method, as this, in itself, vitiates the result. This may be seen by referring to sample A. already noted in the beginning of the paper. In this sample 25.60 per cent. of phosphate of lime was obtained by the molybdate-citrate method, and, as stated, 25.06 per cent. by the citrate method, when 0.5 gm. of citric acid (which was sufficient) was added. Now  $25.06 + 0.50 \left( = \frac{1}{20} \right) = 25.56$  per cent., which is very close to the standard molybdate-citrate result. If an addition of  $\frac{1}{20}$  be made to the results obtained after the addition of 1 and 2 grms. of citric acid, it is seen that the correction does not hold good.

The presence of a moderate amount of iron does not, in itself, in any way influence the value of the correction.

#### *Reagents used in the above Experiments.*

**Molybdenum Solution.**—80 grms. of molybdic acid are dissolved in 80 c.c. of ammonium hydrate (0.880) plus 120 c.c. of water, then slowly poured into 300 c.c. of nitric acid (1.42) plus 300 c.c. of water, and the whole diluted to one litre with distilled water.

100 c.c. of this solution will precipitate 0.27 gm.  $\text{P}_2\text{O}_5$ .

**Magnesia Mixture.**—75 grms. ammonium chloride, with 62 grms. magnesium chloride (cryst.), and 200 c.c. of ammonium hydrate (0.880), to 1 litre with distilled water. 10 c.c. of this solution will precipitate 0.18 gm.  $\text{P}_2\text{O}_5$ .

**Nitric Acid (dilute).**—5 c.c. (sp. gr. 1.42) to 100 c.c. with distilled water.

**Ammonium Hydrate (dilute).**—25 c.c. (sp. gr. 0.880) to 100 c.c. with distilled water.

**Ammonium Hydrate** (sp. gr. 0.880).—20 c.c. added to each experiment before running in magnesia mixture.

**Citric Acid and Ammonium Oxalate** in fine powder.

#### *The Processes used.*

**The Molybdate Method.**—To the solution of the sample is added 20 c.c. of  $\text{NH}_4\text{HO}$  (0.880), then  $\text{HNO}_3$  (1.42) till in excess by five drops, and then excess of molybdenum solution, slowly and with stirring, the solution of the sample being at 55 to 60 °C. After settling clear in a warm place, filter, wash thoroughly with 5 per cent.  $\text{HNO}_3$ , dissolve in stream of 25 per cent.  $\text{NH}_4\text{HO}$  through filter till 200 c.c. have passed through, and add a fair excess of magnesia mixture. Filter next morning, wash, dry, ignite (not blow-pipe), and weigh.

**The Molybdate-Citrate Method.**—As above, but in addition add 0.1 gm. of citric acid to the ammoniacal solution of the yellow precipitate before adding magnesia mixture.

**The Citrate Method.**—To the solution add the given amount of citric acid; boil, add excess of ammonia, then excess of acetic acid, then ammonium oxalate; boil, filter, and wash (volume now 200 c.c.). Add 20 c.c.  $\text{NH}_4\text{HO}$  and fair excess of magnesia mixture. Filter next morning, dissolve precipitate in dilute  $\text{HCl}$ , add 0.1 gm. of citric acid, dilute to 100 c.c., add 20 c.c.  $\text{NH}_4\text{HO}$  (0.880), stir,

settle one hour, filter, wash twice with dilute  $\text{NH}_4\text{HO}$ , dry, ignite (not blow-pipe), and weigh.

#### DISCUSSION.

Mr. OTTO HEHNER said that the subject-matter of the paper seemed familiar. No doubt the correct estimation of phosphoric acid was important; but the amount of literature already devoted to it was so considerable as to constitute a scientific library in itself. Certainly much of Mr. CAMERON's paper would be found in published works.

Mr. CAMERON, in reply, said it was generally admitted that if no correction were made there was a great liability to error. In analytical work he had made that principle the basis of his work and experiments.

#### THE STRENGTH OF COMMERCIAL FORMALDEHYDE SOLUTIONS.

BY WILLIAM A. DAVIS.

OWING to improvements that have been made in the past three or four years in the methods of removing methyl alcohol from commercial formaldehyde solution, the table given by H. Lüttke, in Fischer's *Jahresbericht* (1893, 512), for the specific gravities of solutions of formaldehyde of various strengths, is no longer correct. This

Specific Gravity at 60° F.	Percentage Formaldehyde by Weight.	Formerly given.	Difference in Percentage.	Percentage Formaldehyde by Volume.
1.0025	1	1.25	-0.25	1.0
1.005	2	2.3	-0.3	2.0
1.0075	3	3.5	-0.5	3.0
1.0100	4	4.3	-0.3	4.0
1.0125	5	4.7	+0.3	5.0
1.015	6	5.0	+1.0	6.1
1.0175	7	6.25	+0.75	7.1

1.070	26	28.0	-2.0	27.8
1.073	27	29.5	-2.5	29.0
1.076	28	32.0	-4.0	30.1
1.079	29	34.5	-5.5	31.3
1.083	30	37.0	-7.0	32.5
1.087	31	40.0	-9.0	33.7
1.092	32	..	..	34.9
1.096	33	..	..	36.2
1.100	34	..	..	37.4
1.104	35	..	..	38.6
1.109	36	..	..	39.9
1.113	37	..	..	41.2
1.117	38	..	..	42.5
1.121	39	..	..	43.7
1.125	40	..	..	45.0

becomes of importance, owing to the fact that manufacturers often test the strength of their product only by taking its specific gravity, before its consignment to the public.

The above table, giving a comparison of the corrected values with those formerly given, shows that in the case of the stronger solutions, an error as great as 25 per cent. of the correct strength can arise in this way; indeed, it was through such errors arising that I was induced to draw up a corrected table of specific gravities for solutions of formaldehyde up to 40 per cent. in strength.

The results were obtained with solutions of commercial formaldehyde, supplied by C. A. F. Kahlebaum, freed as far as possible from methyl alcohol. The analyses of the solutions were carried out mostly by means of the iodometric method recently given by Romijn (*Zeits. ang. Chem.* 36, 18-24), which is at once rapid and exact. Many of the analyses were, however, repeated, and confirmed by the method originally given by Lagler (*Ber.* XVI, 1333).

The results marked with an asterisk were the results obtained as the mean of several experiments; the rest were obtained by interpolation. The specific gravities were taken at 60° F. The percentages by volume give the number of grms. of formaldehyde in 100 c.c. of the solution.

#### DISCUSSION.

The CHAIRMAN said that it was evident that formaldehyde solutions should be valued by analysis and not by specific gravity, which, on account of the ever varying impurities, both as to quality and quantity, could not be reliable. A specific gravity table referring to poor solutions, if the author would draw it up, would possess a permanent value.

Meeting held on Monday, January 4th, 1897.

### THE SMELTING AND REFINING OF CYANIDE BULLION.

BY ARTHUR CALDECOTT, B.A.

(This Journal, 1897, 3.)

#### DISCUSSION.

MR. A. CALDECOTT sends the following reply to the points raised in discussion:—

MR. A. C. CLAUDET's suggestion to use pure zinc in the extractor boxes is impracticable, since precipitation in such a case is very imperfect. This is a fact well known to practical cyanide men, and also that the presence of a small percentage of lead or other metallic impurity in the zinc, whereby a couple is formed, is a positive advantage.

Bullion obtained by smelting slimes which have simply been roasted is, in actual practice, lower than 800 fine—and not 900 fine, as stated by Dr. A. F. Fuerst. The bullion obtained by the method mentioned in the paper was 814 fine. The matter of sampling and assaying cyanide bullion has recently been fully discussed at meetings of the Chemical and Metallurgical Society of South Africa.

Bisulphate of potash may be used with advantage instead of sulphuric acid when the acid treatment is practised. It is a cheap by-product in the manufacture of dynamite, and, whilst containing 36 per cent. available sulphuric acid, presents considerable advantages in transport and handling.

To lessen the gold contents of the slag, a mould to receive the contents of the crucible may be used which has a small hole bored in the side a couple of inches from the bottom. Whilst pouring, this hole is plugged up with clay, and a few minutes afterwards, when the surface of the slag has solidified, an iron rod is thrust through, whereupon the still molten slag inside runs out. During the interval after pouring, any shots of metal contained in the slag settle to the bottom, or are caught on the partially chilled layer next the sides of the mould. Hence the outflowing slag is, as experiment shows, nearly gold-free. That portion of the slag which remains as a shell in the mould can be returned to the crucible when the next charge is melted.

SESSION 1896-97.

Meeting held on Friday, May 7th, 1897.

THE PRESIDENT IN THE CHAIR.

### CONTRIBUTIONS TO THE ANALYSIS OF FATS. VIII.—THE ACETYL VALUE.

BY DR. J. LEWKOWITSCH.

The acetyl value, introduced by Benedikt into the analysis of fats as a chemical constant, furnishes a measure of the proportion of hydroxylated fatty acids in fatty oils or fats.

The method of determining the acetyl value as proposed by Benedikt is based on the principle that hydroxy acids, on being heated with acetic anhydride, exchange the hydrogen atom of their alcoholic hydroxyl group or groups for the radicle of acetic acid according to the following equation, taking ricinoleic acid as an example:—

The acetylation process and the determination of the acetyl value was carried out, according to Benedikt and Ulzer, in the following manner:—The free fatty acids were prepared in the usual manner and heated together with acetic anhydride. The mass was next boiled with water and washed until the acetic acid was entirely removed. The acetylated fatty acids were then filtered off, and both their acid and saponification values determined in the well-known manner. The difference between the two values thus found was termed "acetyl value."

The neutralisation and saponification of the acetylated fatty acids was supposed to take place in two stages, according to the following equations:—

I.

II.

Accordingly, the acetyl value would indicate the number of milligrammes of KOH required for the neutralisation of the acetic acid obtained on saponifying 1 gram. of the acetylated insoluble fatty acids.

The hydroxyl in the carboxyl group of the fatty acids was therefore, in the light of the explanations given, not affected during the acetylating process. Hence fatty acids containing no alcoholic hydroxyl group, such as stearic, oleic, &c., should not yield an acetyl value, and the acid and saponification values should be identical in these cases.

I have, however, shown (this Journal, 1890, 660) that pure capric, lauric, palmitic, stearic, cerotic, and oleic acids gave very considerable acetyl values when treated by Benedikt and Ulzer's process. This result could only be explained by the fact that the fatty acids named had been converted into their anhydrides, the acetic anhydride acting in the manner explained by the following equation:—

When the acids were dissolved in cold alcohol for the purpose of titrating, on adding the potash hydrolysis (saponification) of the anhydrides took place at once to a certain extent, and as the acid combined with a certain quantity of potash an (apparent) acid value of the substance was obtained. When, however, the anhydrides were shaken up with water, the first drop of potash gave a pink coloration (in the presence of phenolphthalein), which disappeared but slowly. Thus in the alcoholic solution partial hydrolysis of the anhydrides took place, hydrolysis ceasing when an equilibrium was established in the solution. Under these conditions apparent acetyl values were obtained, being, in truth, nothing but fictitious values.

Hydroxylated fatty acids are certainly acetylated when boiled with acetic anhydride, but simultaneously the acetylated acids are converted into their anhydrides in consequence of the dehydrating action of the acetic anhydride used in excess. On being boiled subsequently with water to remove acetic acid, a portion of the anhydrides may or may not become hydrolysed, yielding possibly a mixture of free acetylated acids and acetylated anhydrides. When this is dissolved in alcohol and titrated with caustic potash, after neutralisation of the free acids, if any, partial hydrolysis will set in, as explained above, and thus an acid value will be obtained (Benedikt's "acetyl acid value"). But such acid value will be lower than the true acid value of the acetylated fatty acids, the anhydrides remaining unacted on to a certain extent.

Consequently the saponification value of the acetylated product (Benedikt's "acetyl saponification value") will be found too high, the not-hydrolysed anhydrides being then saponified by the boiling alcoholic potash. The difference between the saponification and acid values, supposed to be the acetyl value of the acids, will therefore, be devoid of any quantitative meaning.

The same argument holds, of course, of mixtures of ordinary fatty acids of the acetic and oleic series and hydroxylated acids.

No ready method being available to ascertain whether complete hydrolysis of the anhydrides has taken place after boiling out with water (the anhydrides of the higher fatty acids proving themselves very stable indeed, even on boiling with water), I rejected Benedikt's method altogether and proposed to determine the true acetyl value by actually titrating the amount of acetic acid assimilated by the hydroxylated acid in the form of acetyl,  $\text{C}_2\text{H}_5\text{O}$ , and given up, on saponification, as acetic acid to the alkali (this Journal, 1890, 846).

This is done by boiling the acetylated product with alcoholic potash and estimating the acetic acid formed in a similar fashion, to that adopted in the determination of volatile acids by Reichert's distillation process. There is, however, this important difference that the total amount of volatile acids, in the present case, acetic acid, is driven off,

so that the distillation is carried on until practically no acidity is shown by the distillates. This occurs, as a rule, when about 500 or 700 c.c. have been distilled over. The distilled liquors are then titrated with standardised potash, phenolphthalein being the indicator; the number of c.c. of normal potash used per gramme of the acetylated product multiplied by 56.1 represents the acetyl value of the insoluble fatty acids.

On repeating my experiments I proved that my method yielded correct results. But at best the process is a somewhat tedious one. Furthermore, it has that important drawback, that the acetyl value refers to the insoluble fatty acids rather than to the oils and fats themselves. This naturally tends to obliterate at the outset important differences existing between the various glycerides, for in the process of preparing the fatty acids volatile fatty acids are washed away and the characteristic differences of such fats as, *e.g.*, butter and tallow, may entirely disappear. There is the further drawback that during the operations entailed in liberating and drying the free fatty acids, oxidation may set in with possible formation of hydroxy acids, resulting in an increased acetyl value.

It appears, therefore, preferable to work with the original fats and thus to bring this important constant into line with the other constant, such as saponification value, iodine value, &c. Since the basic radical, glyceryl, is in common to all the glycerides it is evident that any difference between the mixed fatty acids of the various oils and fats must find its corresponding expression in the different behaviour of the oils and fats themselves. This is, indeed, borne out by various reactions, such as the action of sulphuric acid on the fatty acids on the one hand and the oils and fats on the other, due allowance being made for the constitutional difference between acids and their glyceryl ethers (esters).

It was then found that the oils and fats containing hydroxy acids assimilate acetyl radicals. In their case, however, no complication can arise through formation of anhydrides, so that from neutral oils and fats neutral—though acetylated—esters were obtained. The small quantity of free fatty acids naturally occurring in oils and fats may be left out of consideration here, as not appreciably affecting the result.

It would thus appear that by taking the difference of the saponification values of the acetylated esters and the original esters, or, to use less scientific parlance, of the acetylated oils and fats and the original oils and fats the acetyl values would be obtained. If it could be agreed amongst chemists that this difference should be looked upon as the true acetyl value the matter might end there. But, obviously, it would not be a very rational proceeding, for the acetylated products naturally have a higher molecular weight than the original oils and fats. Thus the two substances are not strictly comparable, unless, indeed, we reduce the weight of the acetylated substance by calculation to the corresponding amount of original substance.

I therefore prefer to ascertain the acetyl value by determining direct the amount of acetic acid formed on saponification. I proceed as follows:—

10 grms. of an oil or fat (or any other convenient number of grms.) are boiled with an equal volume of acetic anhydride for two hours in a round-bottomed flask attached to an inverted condenser. The mixture is then transferred to a large beaker, mixed with several hundred c.c. of water and boiled for half an hour. A slow current of carbonic dioxide is conveniently passed into the liquor through a finely drawn out tube reaching nearly to the bottom of the beaker; this is done to prevent bumping. The mixture is then allowed to separate into two layers, the water is siphoned off and the oily layer again boiled out in the same manner until the last trace of acetic acid is removed. This is ascertained by testing with litmus paper. The acetylated product is then freed from water and finally filtered through filter paper in a drying oven.

This operation may be carried out quantitatively, and in that case the washing is best done on a weighed filter. On weighing the acetylated oil or fat, an increase of weight would prove that assimilation of acetyl groups

has taken place. This method may be found useful to ascertain preliminarily whether a notable amount of hydroxylated acids is present in the sample under examination.

2 to 4 grms. of the acetylated substance are then saponified by means of alcoholic potash solution as in the well-known determination of the saponification value. If the "distillation process" be adopted it is not necessary to work with an accurately measured quantity of standardised alcoholic potash. In case the "filtration process" be used, the alcoholic potash must be measured exactly. (It is, however, advisable to employ in either case a known volume of standard alkali as one is then enabled to determine the saponification value of the acetylated oil or fat.) Next the alcohol is evaporated and the soap dissolved in water. From this stage the determination is carried out either by (a.) the "distillation process" or (b.) "filtration process."

(a.) *Distillation Process*.—Add dilute sulphuric acid (1:10) more than to saturate the potash used, and distil the liquid as is usual in Reichert's distillation process. Since several 100 c.c. of water must be distilled off, either a current of steam is blown through the suspended fatty acids or water is run into the distilling flask, from time to time, through a stoppered funnel fixed in the cork, or any other convenient device is adopted. It will be found quite sufficient to distil over 500 to 700 c.c., as the last 100 c.c. practically contain no acid. Then filter the distillates to remove any

insoluble acids carried over by the steam, and titrate the filtrate with decinormal potash, phenolphthalein being the indicator. Multiply the number of c.c. by 5.61, and divide the product by the weight of substance taken. This gives the *acetyl value*.

(b.) *Filtration Process*.—Add to the soap solution a quantity of standardised sulphuric acid *exactly* corresponding to the amount of alcoholic potash employed, and warm gently, when the fatty acids will readily collect on the top as an oily layer. (If the saponification value has been determined, it is, of course, necessary to take into account the volume of acid used for titrating back the excess of potash.) Filter off the liberated fatty acids, wash with boiling water until the washings are no longer acid, and titrate the filtrate with decinormal potash, using phenolphthalein as indicator. The acetyl value is calculated in the manner shown above.

It goes without saying that both methods must give identical results. A glance at the table will show that this is the case. The method (b.) will be found shorter and more convenient than (a.).

We now arrive at the definition:—

*The acetyl value indicates the number of milligrammes of KOH required for the neutralisation of the acetic acid obtained on saponifying 1 gm. of the acetylated oil or fat.*

No.	1. Kind of Oil or Fat.	2. Acetylated Oil or Fat.			3. Neutralised Filtrate from 111. acidified and distilled. Acetyl Value calculated.	4. Insoluble Fatty Acids from 3 distilled. Used for neutralising Distillate Decinormal KOH.

\* Should be accepted with reserve.

To further check the correctness of the process (b.), in some cases the neutralised filtrate was acidified and the acetic acid distilled off again, when the same number as that given in col. 2 III. was found. The insoluble fatty acids on being subjected to distillation in a current of steam proved themselves free from volatile fatty acids, as shown in col. 4.

The oils and fats given in the table under No. 1-11 contain practically no volatile fatty acids, as evidenced by their extremely low Reichert values. It is clear that in the case of those glycerides that possess notable Reichert values, such as croton oil, cocoanut oil, and butter fat—No. 12-14 of the table—a complication arises, and it might appear that just for this very reason it would be advisable to work on the insoluble fatty acids after elimination of the volatile acids, or, at all events, of the bulk of them, and then determine their acetyl value. This objection, however, is of no importance, and I shall show in a subsequent paper how the true acetyl value is determined. Meanwhile the acetyl values given for No. 12, 13, and 14 should be

considered as representing a measure of both volatile and hydroxylated acid, and should therefore be accepted with reserve.

I confine myself at this occasion to proposing these processes as readily workable ones for the determination of the acetyl value without discussing the conclusions to be drawn from the numbers given. These numbers deviate considerably from those published by Benedikt and Ulzer (cfr. Lewkowitsch, *Chemical Analysis of Oils, Fats, Waxes, &c.*, p. 251), and their figures must therefore be abandoned. Acetyl numbers published during the last years by several chemists fall under the same stricture, and their revision is therefore necessary.

It should be noted that if the oil or fat under examination contains *free alcohols*—phytosterol, cholesterol—the acetyl value will be a measure of both the hydroxy acids and the free alcohols.

If the free alcohol is isolated, its acetyl value (*see below*) should be determined as well. The difference between the acetyl value of the original oil or fat and the acetyl

number proportionate to the amount of free alcohol present, will be the true measure of the proportion of hydroxy acids.

The determination of the acetyl value of a *free alcohol* offers no difficulty. On acetylating the alcohol, its acetate is formed; the saponification value of the latter is also its acetyl value, the alcohol having, of course, no saponification value.

The examination of natural waxes, characterised by the occurrence of free alcohols is in hand, and their acetyl values will be given in a subsequent paper.

In conclusion I wish to express my thanks to my assistant, Mr. C. D. Robertshaw, to whom I am indebted for the analytical results stated in the table.

## MICRO-CHEMICAL EXAMINATION OF LEAD-ANTIMONY, TIN-ANTIMONY, TIN-ARSENIC ALLOYS, &c.—PART II.

BY JOHN E. STEAD, F.I.C.

IN reviewing the work of other investigators in my first paper, by an oversight no notice was given of the very valuable paper "On the Structure of Metals: its Origin and Changes," by Mr. F. Osmond and Prof. Roberts-Austen, read before the Royal Society last year. This paper treats on the mechanical properties and micro-structure of gold containing about  $\frac{2}{100}$ th per cent. of other metals. They classify them into classes according to the nature and thickness of the joints, as follows:—

"1st. Pure gold alloys with Zr, Al, Rh, Pd, Zn; joints which are usually non-crystalline, of a thickness which equals 0 to 2  $\mu$  ( $\mu = 0.001$  mm.); the mathematical joints, or very fine ones are dominant.

"2nd. Alloy of lithium: the thickness of the joints equals 0 to 3.5  $\mu$ ; the thick joints are crystalline, but are rare and disconnected; the mathematical joints, or very fine joints, are dominant.

"3rd. Alloys with Sb, Se: crystalline joints, which are often broken; the thickness of these equals 1  $\mu$  to 3.5  $\mu$ , or a mean thickness of 2  $\mu$ .

"4th. The alloys of In, K: crystalline continuous joints, with a thickness of 1 to 4  $\mu$ , or a mean thickness of 2 to 2.5  $\mu$ .

"5th. Alloys with Tl, Bi: crystalline joints, which are continuous, often passing into fissures; the thickness equals 1  $\mu$  to 5  $\mu$ , or a mean thickness of 2.5  $\mu$ . Generally speaking the condition of these joints appears to be closely related to the mechanical properties of the alloy, as will be seen by the following table, published in the Philosophical Transactions of the Royal Society, Vol. 179, 1888, A., p. 339."

Table showing the Properties of Gold when Alloyed with 0.20 per Cent. of various Elements.

Name of Added Element.	Tensile Strength.	Elongation Per Cent. on Three Inches.	Impurity Per Cent.	Atomic Volume of	Reduction of Area at Fracture per Cent.

\* These test pieces drew out after the manner of pitch; that is, as a viscous solid.

They also treat, in a very interesting chapter, on some phenomena of annealing, and prove that the large grains of the melted metal became subdivided after heating for five minutes to between 200° to 250° C. into a number of small polyhedral grains, when bismuth, thallium, antimony, and aluminium were present, whereas pure gold and the alloys with K, Pd, Zn, Rh, Li, Se, and Zr did not undergo any change; and conclude that, generally speaking, it seems that bismuth, thallium, antimony, and aluminium, when present in the proportion of about 0.2 per cent., behave in respect to gold in the same way as carbon does to steel, but at a much lower temperature.

Since I last lectured before this Section I have received the March Bulletin of the Société d'Encouragement pour

l'Industrie Nationale, which contains a most interesting communication by Mr. M. G. Charpy, on the Microscopic Study of Metallic Alloys. In this work Mr. Charpy has fully described the structure of some of the alloys described in my paper, and it is satisfactory to note that our conclusions do not disagree—at least, to any important extent.

The alloys studied and described by Mr. Charpy are as follows:—

Lead and antimony.  
Lead and tin.  
Zinc and aluminium.  
Bismuth and tin.

Copper and antimony.  
 Bismuth and antimony.  
 Copper and tin.  
 Antimony and tin.  
 Antimony and silver.  
 Copper and zinc.

It will be seen from this list that Mr. Charpy has investigated three of the series of alloys I described in my first lecture, *viz.*, the lead-antimony, tin-antimony, and copper-tin series.

So far as our microscopic work is concerned, our results agree closely, but Mr. Charpy has more fully studied the structures of the lead-antimony alloys containing less than 13 per cent. antimony than I had done at that time; and I, on the other hand, had supplemented the microscopic investigation with a chemical research, with the object of determining the composition of the separated crystals.

**Lead and Antimony.**—Mr. Charpy had great difficulty in polishing the alloys, containing less than 13 per cent. of antimony, and it will be remembered that I experienced the same thing, and resorted to the examination of the surface of the solidified eutectic of the lead-antimony alloys instead of the polished and etched surfaces. On further attempts to develop the structure by etching this eutectic, and of the alloys containing less than 13 per cent. antimony, I have recently been more successful. After long-continued action of dilute nitric acid on the eutectic, it was observed that a thick adherent layer, almost black, covered the polished surface. A portion of this was removed, and was, after well washing with water, tested for lead, and as it was found to be absent we may conclude it was pure antimony.

After rubbing away the dark layer by gentle friction under running water, the metal below presented a most characteristic microscopic appearance. At fairly equable distances apart, what appeared to be laminae radiated from nuclei, and continued in right lines until met by similar radiations from other nuclei. The accompanying photograph clearly illustrates this.

Fig. 1.

Lead-Antimony Eutectic.  $\times 50$  diameters.

The appearance is similar to that of nodules of pyrites, with radial structure or spherulites in obsidian.

On examining the dark crust after gently crushing so as to separate the individual particles of antimony, it was found that it consisted of very fine, thin plates, as the microscopic appearance of the etched specimen would lead us to suppose; and these, on further pressing, appeared to split up into excessively fine rod-like bodies, which, but for their absolute opacity, might be mistaken for certain forms of bacteria.

Every metal I have examined, and many alloys, appear to be built up of laminae, and such laminae are themselves built up of crystals of definite form. The lead eutectic is no exception to the rule, and it appears certain that it is constituted of alternate laminae of lead and antimony, as Mr. Charpy suggests. The composition of this eutectic is,

as before pointed out, that of the atomic proportion of  $Pb_3Sb_2$ ; but there can be no doubt, judging from the facts just referred to, in the solid state they are not in chemical union.

Whether this eutectic is analogous to a cryohydrate, or at its melting point when fluid is a chemical compound which afterwards, simultaneously with solidification, splits up into its elements, remains to be determined. The fact that it has a distinct tendency to crystallise in hexagonal forms, whereas both constituents separately at the solidification point give skeleton octahedra, strengthens the latter hypothesis. Fluid grey iron simultaneously solidifies and splits up into iron and graphite, and may be an instance analogous to what takes place in the eutectic.

It has already been shown by the critical points on cooling, that in the alloys containing less than 12.7 per cent. antimony, the lead crystallises in the eutectic. Mr. Charpy has demonstrated that this is so by the microscope, and I have recently obtained an excellent illustration of this from an alloy containing 10 per cent. antimony and 90 per cent. lead, in which the dendritic crystals of lead are clearly developed in an eutectic matrix, thus confirming Charpy's results.

Fig. 2.

Lead, 90 per cent. Antimony, 10 per cent.  
Polished and etched with acid.  $\times 50$  diameters.

The structures, or surface markings of small ingots of alloys after solidification, without any preparation, frequently are similar and sometimes identical with those obtained by the more laborious methods of grinding and polishing. This is the case with some of the alloys of tin and copper, tin and arsenic, tin and lead, lead and antimony. The surface of an ingot or small cake of a lead-antimony alloy containing 10 per cent. antimony, has upon it the skeleton octahedron lead crystals and the spherulitic structures of the eutectic side by side. If the antimony present does not exceed 6 per cent., the eutectic sinks below the mass of lead crystals, which solidify first, leaving the latter in strong relief; it is therefore impossible, in such cases, to obtain on the surface indications of the structure of the eutectic.

As the eutectic on digestion in nitric acid has all of its lead dissolved away, leaving the antimony intact, and in a mass of the same bulk as the original alloy, and also fairly coherent, it was believed that when there were free fir-tree crystals of lead in the solid eutectic, they would be dissolved away by acid, leaving cavities where they originally existed, and that on breaking the coherent and porous mass after drying it, these cavities would be visible on the fractured surfaces. On making the experiment this was proved to be the case; the empty areas where at one time lead had crystallised were clearly visible.

The solid eutectic of lead and tin consists of similar masses of spherulites. They can be easily seen on the surface of an ingot carefully cooled, and if, when the alloy is partially solidified and is poured out suddenly upon an iron plate, they are readily detected, for they stand out as

little nobs above the surface of what was, at the time of pouring, liquid metal. The spherulites being solid, the still liquid metal falls away, leaving the nobs referred to.

When alloys of antimony and lead with between 15 per cent. and 40 per cent. are caused to solidify very slowly, the crystals of antimony do not separate in the mass and then float to the surface, but begin to form at the surface and slowly grow downwards, and the crystals branch out, and are more or less perfectly joined together, and the ends terminate in the eutectic below.

*Antimony and Tin.*—Since reading the first part of this paper, the study of these alloys has been further investigated. It would not appear that Mr. Charpy has fixed the composition at which cubic crystals cease to be formed on cooling. This point, according to my work, appears to be reached when the antimony approximates to 7.5 per cent. When this alloy is perfectly polished, the joints of the grains appear light on a slightly darker ground, and it would seem, contain a compound harder than that of the main body of the grains. After slightly etching with very dilute nitric acid, these brighter parts develop to a darker shade than the centres. In fact, the appearance is exactly reversed. When the section is bent, fracture commences at the joints.

All these considerations lead us to the conclusion that there is a fusible eutectic in the joints of the grains, richer in antimony than that in the main mass.

On taking the lower part of an alloy containing 10 per cent. antimony which had been so slowly cooled as to permit of the hard cubic crystals floating to the surface, this also had the same appearance. On digesting this portion of the alloy for several days in weak hydrochloric acid, a dark-coloured, soft, and easily detached layer remained adhering to the surface. It apparently consisted of an amorphous structureless powder which soiled the fingers like lampblack. No structure or form could be detected by the highest power of the microscope. The small quantity available was analysed, and a considerable amount of tin was proved qualitatively to be present. A larger quantity is in process of being separated, which, when obtained, will be more thoroughly examined.

In the alloy containing 4 per cent. antimony, the structure appeared to be similar to the last.

All the specimens containing between 7.5 per cent. and 0.5 per cent. antimony crystallised in the same forms as pure tin, and the crystalline markings of octahedral skeletons were almost identical.

Mr. Charpy believes that he detected needles of pure tin in a 5 per cent. antimony alloy; but it is doubtful whether pure tin could be detected, for every polished section, even of alloys containing very little antimony, after treatment for a short time with dilute nitric acid or hydrochloric acid, was darkened by an amorphous black deposit slightly darker and most pronounced at the joints of the grains, and the highest power could not resolve any separate constituent.

The photograph given by Mr. Charpy resembles an appearance which can be obtained readily enough by the action of very dilute acid for a few seconds, and is exactly what I have before described, and proves that there is a larger proportion of antimony at the joints than in the mass. When, however, the etching action is continued, the whole surface is veiled over, those portions at the joints still taking the lead in relative darkness. To the naked eye the etched surface assumes the same appearance as bright copper assumes when it has received a coating of arsenic in the Reinsch test.

Perfectly pure tin, prepared by electrolysis, after fusing and polishing, gave no bright junction lines, and on slightly etching, developed a granulation identical with the alloys containing a little antimony; with this exception, that the joints remained relatively brighter than the mass, and after long etching no dark antimonial veil could be obtained. We conclude therefore that tin and antimony, or tin and a compound of tin and antimony, solidify together, either as an amorphous mixture, or solidified solution; and that, if the tin in such alloys is in the free state, it is in such close contact and so intermixed with the antimonial compound or free antimony as to be unrecognisable under the highest power of the microscope.

With regard to the composition of the cubic crystals which separate from alloys containing above 7.5 per cent. antimony, I proved in my first communication, those from the 25 per cent. alloy had the composition of  $\text{SnSb}$ , but after what we have learnt with regard to the crystals in copper-tin, to which we shall presently draw attention, it will be necessary to separate them from several alloys containing different quantities of antimony, and analyse each separately, before we can conclude that they are or are not of that constitution. The same precaution is necessary with regard to the crystals in tin-arsenic and tin-phosphorus compounds.

I have shown that the melted and solidified cubic crystals containing equal atomic proportions of antimony and tin, split up into the eutectic alloy and a compound containing a relatively larger proportion of antimony. After very slow cooling such an alloy, I have obtained much better results, and have demonstrated that all of the white plates are relatively more highly charged with antimony in the centre than at the sides, and that some have a clearly defined, separate, hard constituent in the centre.

In general, the results of Mr. Charpy and my own agree most closely. The slight difference observed in the structures of the 25 per cent. antimony-tin alloy would be most readily accounted for by differences in the rate at which the alloys were cooled.

I have myself obtained the same differences by varying the conditions of cooling.

It is in the alloys containing little antimony (5 per cent.) where we differ more seriously, but here, even, it is not important. Mr. Charpy believes he can see the separate independent tin crystals. I maintain this is impossible.

*Tin-Copper Alloys.*—To chemically examine all the alloys of copper and tin is the work of time. I have not fully examined other than a few of the alloys containing an excess of tin; but as the results are rather different from those obtained by other investigators, it becomes of interest to give them at once, without waiting to complete an exhaustive research.

Microscopic results of tin-copper compounds obtained in my laboratory were exhibited on the screen at my last lecture, in February, but were not given in my printed paper, as the research was so incomplete.

The alloys examined contained between 0.1 per cent. and 40.0 per cent. of copper.

On polishing the slowly cooled alloys and etching with very dilute nitric acid, it was possible to detect, even in the alloy with only 0.1 per cent. copper, fine bright needles; and these increased in size, both in length and diameter, with each addition of copper. In the alloy in which the proportion of copper amounted to 2 per cent., the needle crystals were completely separated by long digestion in dilute nitric acid (1 to 10), followed by treatment with dilute hydrochloric acid, which readily dissolved the hydrated

Fig. 3.

Copper, 30 per cent. Tin, 97 per cent.  
× 50 diameters.

metastannic oxide formed by the nitric acid. The crystals so obtained were well formed, the edges perfectly angular, and the sides bright, smooth, and metallic, having the colour and brightness of polished nickel. In form they were apparently square prisms, and occasionally several of them were found together to form a more or less plate-like structure. With 3 per cent. copper the alloy gave similar crystals, but the tendency to grow into plates was greater than in the others. With 5 per cent. copper the alloy yielded crystals, the greater proportion of which were in plates which crystallised with bright, smooth surfaces. With 10 per cent. the separated crystals were badly formed, and were nearly all in the form of plates with most irregular, granulated, uneven surfaces, but occasionally well-formed needle crystals protruded from the ends of the plates.

From this alloy up to that of the composition of  $\text{Sn}^{\text{II}}\text{Cu}$ , containing 34.7 per cent. copper, all the separated compounds were similar in appearance, and, excepting at the ends of some of the plates, there were no clearly definite crystalline forms present.

All the crops of crystals were analysed, but before doing so they were examined under the microscope, and proved to be free from oxide of tin and from surface oxidation. They were simply tested for copper, the tin being taken by difference, excepting in two cases, when the tin was determined, and the results obtained agreed closely with the difference between the copper present and 100 parts.

The following are the results:—

Alloy.	Crystals separated.	
	Copper.	Tin.
	Per Cent.	Per Cent.
98 per cent. tin, 2 per cent. copper ...	34.58	65.42 $\text{Sn}^{\text{II}}\text{Cu}$
97 " " 3 " " " ...	35.50	64.50
95 " " 5 " " " ...	39.80	60.20
90 " " 10 " " " ...	44.60	55.40 $\text{Sn}_2\text{Cu}_3$
85 " " 15 " " " ...	47.20	52.80
80 " " 20 " " " ...	53.00	47.00
65.3 " " 34.7 " " " ...	56.12	43.88 $\text{SnCu}_2$

Mr. Charpy states that from similar alloys H. le Chatelier and M. Laurie obtained crystals quite pure, having the exact formula of  $\text{SnCu}_3$ . Now  $\text{SnCu}_3$  contains:—

	Per Cent.
Copper .....	61.6
Tin .....	38.4

The crystals obtained from the 2 per cent., 10 per cent., and 34.7 per cent. copper alloys approximate to the formulae  $\text{SnCu}$ ,  $\text{Sn}_2\text{Cu}_3$ , and  $\text{Sn}^{\text{II}}\text{Cu}_2$  respectively, but none of them approach to  $\text{Sn}^{\text{II}}\text{Cu}$ .

In my trials, the first crystals obtained were from the 2 per cent. alloy, and as these appeared to be of definite chemical composition, a large quantity of an alloy was made of the composition  $\text{SnCu}$ , and the soluble eutectic was then dissolved and the separated compounds analysed. This proved to have the composition approximating to  $\text{SnCu}_3$ . The micro-structure showed the presence of the edges of thick, bright plates and a compound readily dissolved away, which left a darkened etched surface which was practically pure tin. It is evident that such a compound  $\text{SnCu}$  could not be melted by itself without suffering change, and is another instance of the same thing which occurs when carbide of iron, antimonide, arsenide, and phosphide of tin are melted by themselves.

It is possible that all the various separate compounds, containing more copper than sufficient to make  $\text{SnCu}$ , may be mixtures of molecules of that composition, with other molecules containing a larger atomic proportion of copper. The fact that needle crystals were detected at the ends of some of the plates, and that certain retardations in cooling were observed by Prof. Roberts-Anstons and Mr. Stansfield, rather strengthen the view that they may contain more than one chemical constituent.

The facts are undisputable, however, that the copper steadily increases in the separated crystals with each increment of copper in the alloy.

Fig. 1.

Copper, 10 per cent. Tin 60 per cent.  
30 diameters.

When the proportion of tin is 60 per cent. the fusible tin eutectic is most readily noticed, but when 56 per cent. copper and 44 per cent. tin are present it is absent, and it is difficult to develop the structure. I have not, however, thoroughly studied the alloys higher in copper than 10 per cent.

**Eutectics.**—About 18 months ago, I demonstrated and Mr. Charpy has also shown that there is some relation in structure between the pearly constituent discovered by Dr. Sorby in steels and that of eutectics in alloys. The pearly effect in steel after etching, as is well known, is caused by parallel laminae, often very much curved, of a hard constituent of the composition of  $\text{Fe}_3\text{C}$ , projecting in relief on the polished surface of steel, the alternative laminae of soft iron having been either worn away by polishing or dissolved away by acid. The eutectics of 23 per cent. copper and 77 per cent. antimony, and of bismuth and tin, give fine pearly structures. The eutectic of tin and antimony does not give any pearly structure, for the simple reason that the hard and soft constituents are not separate in the form of lamellar plates. The eutectic of lead and antimony consists of alternate plates of soft and hard constituents, and theoretically should give a pearly structure; but I have not succeeded in obtaining it.

The eutectic of tin and lead, under high-power magnification, although crystallising in gross spherulites, appears to consist of two constituents, worm-like in structure; but I have failed to obtain any pearly appearance.

The eutectic of lead, antimony, and tin is brilliantly pearly, and so also are the eutectics of several of the ternary alloys; and under high power in all such cases they are resolved into comparatively gross alternate layers of a hard and soft constituent.

The structure of the eutectic of an alloy containing 80 per cent. lead, 5 per cent. tin, and 15 per cent. antimony is a marked instance of this, and also indicates a very beautiful crystallite formation.

In concluding this second paper, I must apologise for its incompleteness; but I am continuing the investigation, and shall, if agreeable to the Society, continue to bring before it the results of my future work.

#### ERRATA FOR PART I.

No. 2 and 3 diagrams are reversed. No. 2 should be No. 3, and No. 3 should be No. 2 (this Journal, 1897, 202).

The description of diagram No. 9 should have been: Tin, 99.75 per cent.; phosphorus, 0.25 per cent. (*ibid.* 206).

**NOTE.**—Prof. Behrens has given a good account of both copper-tin and tin-copper alloys in his work, "*Die Mikroskopische Gefüge der Metalle und Legierungen.*"

### ON A PURE CULTIVATION OF A BACILLUS FERMENTING BRAN INFUSIONS.

BY J. T. WOOD AND W. H. WILLCOX, B.Sc. (LOND.)

*Isolation of Pure Culture.*—In our previous communication on bran fermentation as applied in the manufacture of light leathers (this Journal, 1893, 422), we gave an account of the actual fermentation and its products, together with the mode of action on the bran and on the skins for which this fermentation is used, reserving to the present paper an account of the products of a pure cultivation of the bacteria causing the fermentation.

The cultivation used in the first experiments for this purpose was one isolated in 1889, and used in the cellulose and starch experiments described in the above-mentioned paper.

This cultivation had not been obtained from a single colony from gelatine, and in order to make quite sure that the cultures used were pure, it was decided to make another attempt to isolate the bacillus by plate cultivation. Previous attempts to do this had failed, bacte organisms and gelatine liquefying bacilli developing in such numbers that the plates were spoiled before the organism, which caused the fermentation, had time to develop; besides which the organism, as obtained direct from the drenches, grew with difficulty in the ordinary nutrient gelatine. A special gelatine was therefore prepared of the following composition:—

Gelatine .....	100 grms.
Glucose .....	30 "
*Salt solution .....	200 c.c.
Water.....	800 "

Plates of this gelatine in Petri dishes were prepared from the previously used supposed pure cultures which had been preserved in sealed tubes. These were found to be dead. A modification of the method previously described by one of us (this Journal, 1890, 28) was adopted.

A solution of nutrient glucose was inoculated from a working drench, and as soon as the liquid was observed to become cloudy, a tube of the solid glucose gelatine was inoculated from it by plunging in a platinum needle. In two days the bacteria developed along the needle track. Fig. 1 shows the appearance of the tube four days after inoculation, a bubble of gas being formed in the solid

gelatine. On the following day the tube was broken, and from the portion where gas was given off most vigorously other tubes of solid and liquid media were inoculated. Acid was quickly formed in the nutrient glucose solutions. In the gelatine tubes, the bacteria developed well in the depth.

Fig. 1.

Cultures of and in Glucose Gelatine, showing Bubbles of Gas.

The now purified culture was passed through three more glucose gelatine tubes, each time also a glucose tube being inoculated. From the last of these tubes a very minute quantity was taken 12 hours after inoculation on the point of a platinum needle, and a streak culture made on glucose gelatine. In 24 hours a growth could be seen on the surface of the gelatine in the form of minute dots perfectly separated one from another.

From one of these dots a tube was inoculated and from this several plate cultivations were made. The colonies which developed on these plates were of two kinds, the majority being round, yellowish and of small size, a smaller number spreading out on the surface of the gelatine and slightly iridescent. These surface expansion colonies when examined with a low power appear like a milky drop, with very fine granular contents, the whole surrounded by wavy lines which follow exactly the irregular contour of the expansion. The small round colonies growing in the depth occur in the proportion of about 3 to 1 of the surface expansion colonies. The microscopic appearance of the bacteria composing the two kinds of colonies, is almost exactly similar, they are extremely small and regular in size,  $0.75 \mu \times 0.5 \mu$  to  $0.7 \mu \times 1 \mu$ . When spread upon a slide they are not readily miscible with water, and appear greasy. Both colonies inoculated into glucose tubes produced acid. The existence of these two organisms was confirmed in the following way:—A glucose tube was inoculated from a drench in active fermentation; as soon as the liquid became cloudy, a second tube was inoculated from it by means of a platinum needle; from this tube the fermentation was carried through two more tubes; a plate cultivation was made from the last tube 10 hours after inoculation. Again, the two kinds of colonies developed exactly similar in every respect to those obtained from the streak cultures.

It seems probable from these results, and also from a comparison of the fermentations made with the organisms from an actual drench (this Journal, 1893, 422), and from purified cultures with those from a single organism, which are described in the present paper, that the action in the drenches is a symbiotic one in which two or more organisms taken part.

*The Fermentations.*—During the time occupied by the isolation of pure cultures of the bacteria, two fermentations were conducted with the supposed pure cultures. These fermentations (or rather the second of them, for the first was unfortunately lost through the breakage of a bottle) may prove of considerable interest as throwing some light on the symbiotic action of the two organisms.

\* Potassium phosphate, 1 gram; magnesium sulphate, 0.2 gram; calcium chloride, 0.1; water, 1,000 c.c. *Food* Frankland and Frew, Trans, 1892, 255.

The first fermentation with pure cultures of the bacillus *a* (*B. Furfuris*) obtained from a *single* colony in glucose gelatine, was inoculated on September 16, 1894, the composition of the fermenting liquid being—

Glucose.....	27 grms.
Peptone.....	14 "
Salt solution.....	140 c.c.
Water.....	860 "
Pure calcium carbonate.....	10 grms.

This was contained in a narrow-necked litre flask fitted with a rubber stopper, and narrow delivery tube dipping under mercury, and sterilised with all the usual precautions. The fermentation began on the second day, reached its height from the 6th—8th day, and continued for 39 days, when gas ceased to come off. The examination of the gases will be described later on. When the fermentation was over, the liquid was brought to boiling temperature. It was then examined for the volatile acids in exactly the same manner as we described in our previous paper.

110 c.c. normal HCl was added and distillation commenced; the distillate was acid. The distillation was continued until the distillate ceased to be acid, forming fraction I. Three more fractions were now distilled off, using respectively 10, 20, and 17 c.c. normal HCl. C.F. = 1.014.

The fractions were boiled with excess of BaCO<sub>3</sub>, filtered, the BaCO<sub>3</sub> washed with hot water, the filtrate evaporated to dryness, and the barium salts dried at 130° C. till the weight was constant.\* The salts were then decomposed with strong H<sub>2</sub>SO<sub>4</sub>, ignited, and the barium sulphate weighed. The following is a tabulated statement of the results:—

Fraction.	Weight of Salts.	Weight of BaSO <sub>4</sub>	Per Cent. of BaSO <sub>4</sub>
I.	1.2420	1.0915	87.88
II.	0.9915	0.9170	92.49
III.	1.2155	1.1980	98.56
IV.	0.6350	0.6230	98.11

Calculating fraction I. as a mixture of barium acetate and butyrate, and fractions II., III., and IV. as mixtures of barium acetate and formate,† we get:—

Fraction.	Weight of Salts.	Ba Butyrate.	Ba Acetate.	Ba Formate.
I.	1.2420	0.2630	0.9790	..
II.	0.9915	..	0.8933	0.0982
III.	1.2155	..	0.4400	0.7755
IV.	0.6350	..	0.2552	0.3798
Totals ..	4.0840	0.2630	2.5675	1.2535

Calculating the barium salts into their respective acids, we get:—

Fraction.	Formic Acid.	Acetic Acid.	Butyric Acid.
I.	..	0.4697	0.1488
II.	0.0898	0.4201	..
III.	0.3143	0.2071	..
IV.	0.1539	0.1201	..
Totals ...	0.5580	1.2083	0.1488

The total volatile acids produced amounting to 1.8651 grms.

The residual liquid containing the non-volatile acids was submitted to the test for lactic acid previously used (this Journal, 1893, 424), and it was found to be present.

The method employed for estimating lactic acid in our previous communication proving somewhat difficult, we endeavoured to improve it by extracting the concentrated solution of the non-volatile acids on prepared pumice stone

with ether in a paper thimble contained in a Soxhlet fat-extraction apparatus. After repeated trials we found that this method did not give accurate results. The solution was therefore titrated with  $\frac{1}{10}$  N sodium hydrate, using glazed litmus paper to determine the point of neutralisation. The acidity found corresponded to 2.438 grms. of lactic acid per 1,000 c.c. of the fermented liquid.

We have done several other fermentations with this organism and find the same acids produced and the same gases evolved, the results just given being fully confirmed. At the same time the amount of the acids produced and their proportions vary, that is to say, the quantity of acid from a given fermentation cannot be predicted with absolute accuracy, although the conditions under which we carried out the experiments were made as like as possible.

We give the total acids from four fermentations to show the amount of variation. I. is a symbiotic fermentation caused by organisms *a* and *β*; the remainder are fermentations by *a* alone.

Fermentation.	I.	II.	III.*	IV.

Equivalent to 0.0463 grm. butyric acid.

" 1.1186 " acetic "

" 0.7828 " formic "

or one-half of these quantities per litre of the fermented liquid.

NOTE.—Mr. Adrian J. Brown, of Burton-on-Trent, has been kind enough to examine a sample of the glucose used in the above fermentations, and found the rotary power to be equivalent to 65.6 per cent. pure dextrose. The zinc salt of the lactic acid produced had no rotary power.

The Gases.—In dealing with the gases evolved, we first compared those given off in the fermentation of glucose with that of bran under exactly similar conditions. The fermentation was conducted in open vessels as before described (this Journal, 1893, 123), and the gases were collected and examined in the same way.

\* Vide Note on the Estimation of Butyric Acid, W. H. Willcox, J. Chem. Soc., Nov. 21, 1895.

† Vide J. Chem. Soc. (Trans.), 59, 94, App. II.

\* 2,000 c.c. gave only about the same amount of acids as 1,000 c.c. fermentations. For percentages of acids, see table, p. 513.

Mean of three Analyses.

	Bran and Skins.	Glucose and Skins.
CO <sub>2</sub> .....	23.2	24.5
O <sub>2</sub> .....	2.1	1.5
H <sub>2</sub> .....	19.7	19.8
N <sub>2</sub> .....	20.0	21.2

The composition of the gases is thus almost exactly similar, and, we think, fully proves our previous conclusions as to the change of the starch of the bran into glucoses by means of an unorganised ferment (cerealina).

In the closed fermentations we had previously collected only small quantities of gas over mercury, owing to the difficulty of continuously collecting large quantities which came off during the night.

In the fermentation of September 16, 1894, we collected the whole of the gas given off, taking samples every day over mercury, the gas coming off at night being collected over warm water. Of course this method does not give the total amount of gas evolved with absolute accuracy, but the exact composition of the gases was known from day to day, and the amount of CO<sub>2</sub> absorbed by the water could be calculated with moderate accuracy.

The fermentation was conducted in a narrow-necked litre flask fitted with a narrow delivery tube dipping under mercury, and sterilised with all the usual precautions. The temperature was maintained at 25°–30°, gas was evolved for 39 days, when it ceased to come off, the total amount collected being 3,435 c.c. One-half of this quantity, however, came off in seven days. About 300 c.c. of CO<sub>2</sub> was absorbed by the water during the whole period. The diagram (Fig. 4) shows the manner of evolution of the gases,

Fig. 4.

Evolution of Gases from Pure Cultivation of *B. Purpuris*. The dotted line represents the second fermentation.

the ordinates representing volume of gas and the abscissa lapse of time after inoculation. The following table shows the composition of the gas at different stages of the fermentation. (The fermentation (II.) is the one of which the chemical analysis has been previously given, page 511):—

Composition of Gases evolved in Fermentation of 1,000 c.c. Glucose with pure Ferment. September 16, 1894.

	Day.						Mean.
	5.	9.	12.	19.	26-31.	35-39.	
CO <sub>2</sub> .....	53.7	56.4	44.3	52.6	55.6	43.2	49.9
O <sub>2</sub> .....	1.8	0.5	1.7	1.9	0.8	2.8	1.8
H <sub>2</sub> .....	35.8	34.6	41.2	30.3	34.7	31.8	34.8
N <sub>2</sub> .....	8.7	8.5	12.8	15.2	8.9	22.2	13.5

The total quantity of CO<sub>2</sub> actually collected = 1,563 c.c. = 3.090 grms.; the amount of CO<sub>2</sub> due to decomposition of the CaCO<sub>3</sub> by the acids produced was found to be 667 c.c. = (1.3189 grms.). The vol. of hydrogen collected was 1,086 c.c. = 0.973 grm.

In a second fermentation (III.) we endeavoured to ascertain the exact amount of CO<sub>2</sub> evolved, as in the previous fermentation this had not been done. It was therefore decided to absorb the CO<sub>2</sub> by means of potash.

The fermentation in this case was conducted in a narrow-necked flask of 2,000 c.c. capacity, connected by means of a narrow glass tube with two potash bulbs containing strong caustic potash, and furnished with a delivery tube dipping under water; the whole apparatus stood upon an iron plate, and was maintained at a temperature of 25°–30° in the same manner as the previous fermentation. The gases were evolved for 21 days—a considerable shorter period than the 1,000 c.c. fermentation; but resembling it in that one-half the gas was evolved in eight days. The diagram shows the curve as in the previous fermentation, which it resembles for the first 14 days, afterwards however stopping suddenly. When the fermentation was at an end the flask and contents were heated to boiling point, at the same time a current of air free from CO<sub>2</sub> was drawn through it, and the CO<sub>2</sub> given off being collected in potash bulbs as in the fermentation. Unfortunately the estimation of the CO<sub>2</sub> was rendered valueless owing to an accident.

The table shows the composition of the gases other than CO<sub>2</sub> evolved in this second fermentation.

Gases from Fermentation of 2,000 c.c. (excluding CO<sub>2</sub>) Fermentation III.

	Days.						Mean.
	2-4.	4-5.	5-6.	11.	14-15.	16-17.	
O <sub>2</sub> .....	3.4	2.2	1.5	0.42	0.9	2.4	1.48
H <sub>2</sub> .....	81.3	83.3	82.4	79.0	71.7	72.2	77.72
N <sub>2</sub> .....	15.3	14.5	16.1	20.5	27.4	25.4	20.78

The gas from days 18-21 was unfortunately mixed with air. On comparing the mean composition of gases other than CO<sub>2</sub> collected from both fermentations, we get the following result:—

	Fermentation, 1,000 c.c.	Fermentation, 2,000 c.c.
O <sub>2</sub> .....	3.57	1.48
H <sub>2</sub> .....	63.4	77.72
N <sub>2</sub> .....	27.0	20.78

If now the O and part of the N in the proportion to form air be taken away, the composition of the gases from the two fermentations is found to be almost exactly similar:—

	Fermentation, 1,000 c.c.	Fermentation, 2,000 c.c.
H <sub>2</sub> .....	84.4	83.9
N <sub>2</sub> .....	15.6	16.1
	100.0	100.0

The gases from a third fermentation were almost exactly similar in composition, but the total volume was not measured.

A remarkable fact in this fermentation is the evolution of free N, which seems to be rare, except in the case of putrefactive organisms, as in the vast number of fermentative decompositions due to bacteria, almost the only gases found are carbonic anhydride, hydrogen, H<sub>2</sub>S, and marsh gas.

Gayon (Schutzeberger, "Fermentation," 1876, p. 227), in 1875, in an investigation on the putrefaction of eggs, collected the gas given off from large ostrich eggs, and found

ORGANISMS CAUSING BRAN FERMENTATION.  
PURE CULTURES.

Fig. 2.

a

Fig. 3.

b

in it 29 per cent. of nitrogen; he adds, however, that its presence may be due to the accumulation of a certain quantity of air in the air-bubble before putrefaction.

Beecham (Woodhead, "Bacteria and their Products," p. 125), found that yeast cells under suitable conditions, but sugar being withheld, produced pure nitrogen along with leucine tyrosin, a soluble albuminous substance coagulable by heat, an enzyme, a peculiar gummy substance, phosphates and acetic acid, alcohol and  $\text{CO}_2$ . These are almost the only instances where observers of repute have been convinced of the evolution of free  $\text{N}_2$  by bacteria. We find that since the above work was carried out that Immendorf (Die Stickstoffkonservierung im Stalldünger, Jour. f. Landwirtschaft, XLII. p. 69) has found certain bacteria in dung which form ammonium nitrite, and this body, as is known, splits up at a comparatively low temperature into nitrogen and water.

From the bacteriological as well as the chemical results, it is now evident that the fermentation as it takes place in practice is a symbiotic one in which two organisms play the most important part, and very probably cause the entire fermentation. This is shown by comparing the acids produced by the fermentation in the works with those produced by a mixture of the organisms  $\alpha$  and  $\beta$ , the relative amounts being very close, while in all the fermentations with  $\alpha$  alone a much less proportion of lactic acid is produced, as the following table shows:—

—	Fermentation in Works.	Fermentation $\alpha$ and $\beta$ .	Fermentation $\alpha$ (II.).	Fermentation $\alpha$ (III.).
Formic acid.....	2.8	0.8	11.8	16.0
Acetic ".....	22.5	16.4	27.9	22.7
Butyric ".....	1.2	1.5	3.5	0.9
Lactic ".....	73.5	78.3	56.7	60.2

The acetic acid, as far as we can ascertain, is produced directly from dextrose without the previous production of alcohol, since the presence of the latter is not shown by its tests at any stage of the fermentation. We have also ascertained that the organism is without action on dilute solutions of alcohol, in yeast water, no acid being produced.

We are indebted to Mr. H. S. Shrewsbury for the analysis of some of the gases and volatile acids, and also for the preparation of the diagrams. In conclusion we may state that the investigation of this fermentation in the tannery has been the means of pointing the way to a still more complicated process, viz., "bating." It may even be possible in the future to place these processes on somewhat the same footing as the accurately understood fermentations in the brewing industry although the difficulties in the way are much greater.

#### DISCUSSION.

Mr. JAMES O'SULLIVAN asked if it had been observed whether there was any advantage in employing a bran "bate" in which the fermentation was carried on by the two bacteria mentioned in what might be termed a "practically pure" state. He was of opinion that in practice a bate was found to be more efficient when the fermentation was of a mixed character. Although alcohol had not been noticed, it was possible that the production of alcohol and its oxidation into acetic acid were simultaneous. They had an analogous case in the fermentation of maltose by saccharomyces cerevisiae, in which, during the progress of the fermentation, there was no other sugar observed; yet, they knew that there was present in yeast a ferment capable of hydrolysing maltose into dextrose. Hence, in the case of the fermentation of maltose, the productions of dextrose and its fermentation must be simultaneous.

Dr. Clowes had no intention of criticising the authors' statement, or of questioning the authors in order to elicit

further information. He wished, however, to state his conviction that the work carried out by the authors of the paper might be accepted as trustworthy. These gentlemen worked with the greatest care, and verified their first results by repetition; and there was no doubt that their results could not rest on a more sure experimental foundation. Mr. Wood was to be congratulated on the patient perseverance which he had shown in continuing his special line of research, and the Society would doubtless in future receive further instalments for publication as the research progressed. There was cause for congratulation to Mr. Wood and his co-worker, not only for their successful prosecution of their research, but also for the fact that Sir John Turney took a broad minded view respecting this most important line of investigation, and, as the responsible head of the firm with which Mr. Wood was associated, neither discouraged the prosecution of the work, nor interfered with its publication. The issue of results of this character from laboratories connected with large industrial concerns, should be considered as a voucher that operations were conducted on scientific principles, and should not only inspire confidence in the character of their products, but should also help to remove the doubt frequently expressed, as to the scientific basis underlying industrial pursuits in this country. In the present case Mr. Wood was undoubtedly one of leaders in the scientific improvements of the tanning industry, and his keen interest in the advance of the scientific side of the industry by means of research had placed him in this position, and had caused it to be generally recognised both in this country and abroad.

Dr. J. J. Sudborough asked whether the term pure culture was not used somewhat ambiguously by bacteriologists as it served to denote two quite different forms of culture, viz., 1, a colony obtained from a single cell which must necessarily be an absolutely pure culture; 2, a so-called pure growth obtained by means of fractional cultivation, which, although in many cases probably consisting of a single species, was not to be absolutely relied upon. He further asked Mr. Wood whether they had conclusively proved the presence of formic, acetic, and butyric acids among the products of fermentation, and also whether these were the only volatile acids formed, as otherwise the numbers given were of little use. Dr. Sudborough drew attention to the recent investigations conducted by Dr. Crossley on the separation of volatile fatty acids by Wechsler's fractional neutralisation and distillation method, and asked whether the authors had experienced any difficulty in separating the three acids they mentioned. The numbers in the gas analysis tables also appeared curious, the percentage of oxygen varied without any apparent cause. The authors had not removed the air from their flasks at the beginning of the fermentation, and therefore one would expect the percentage of oxygen to gradually diminish as the air became diluted with the gases given off during the fermentation. According to the authors however (Table, p. 512) the per cent. of oxygen first diminished and then increased without any apparent cause unless leakage were suggested. But in any case the percentage of nitrogen was so great that the fact that the organism evolved nitrogen could be taken as established.

Mr. J. GOLDING said that as an agricultural chemist he should like to thank the authors of the paper for the work they had done. He knew of organisms that could assimilate free nitrogen, but the fact that there were other organisms capable of liberating it was new to him. Was the ether used for the lactic acid extractions dry?

Mr. F. LORT asked if the authors had tried the action of the organism on different salts? He thought the evolution of free nitrogen deserved attention: there were no doubt denitrifying organisms which might undo the work of those that aided the agriculturist.

Mr. THOMAS TYRER said that on receiving notice of the paper he read Mr. Wood's paper of 1891, and Wood and Willeox, 1893, and could only congratulate the authors on continuing such important work, pregnant with useful results to an important industry. It was pretty clear that the days of "rule of thumb" were numbered. Our industrial equality, not to say supremacy, depended upon scientific investigation, and Messrs. Wood and Willeox's work was of the kind required and should be encouraged in every possible way.

NOTE.—Ruge (Sitzungsber. d. Wien. Acad. d. Wiss. Vol. XLIV. 1862, 734) found that the gases of the large intestine contained 57.8 per cent. of  $\text{N}_2$ , and Gamgee remarks "in part a diffuse from the blood, but is certainly in part derived from the bacterial decomposition of proteins." (Gamgee, Phys. Chem., p. 497, Vol. II.)

In the forthcoming issue of the Journal would appear a report from the *Board of Trade Journal* on the German Leather Industry and Technical Schools in connection therewith, which he hoped would be carefully read.

Mr. J. T. WOOD, on behalf of himself and Mr. W. H. Willeox, thanked Dr. Clowes and Mr. Tyrer for their appreciative remarks. In reply to Mr. O'Sullivan the research had shown that the best effect was produced by the action of at least two organisms working together. It was impossible to sterilize the skins as they had previously been passed through a dung bate, and, in his opinion, this was the source of the organisms in question.

They had previously pointed out that the action of the skins was due to the production of gases and organic acids. He did not know of any one organism which fulfilled the conditions so well as the two they had isolated. Possibly Mr. O'Sullivan was thinking of the dung bate, where the action was undoubtedly due to a mixture of organisms.

They had not had time to investigate the cause of failure in the lactic acid extraction, but the ether used was dry.

They had at present only tried the action of the organism *a* on dextrose and bran infusions.

In reply to Dr. Sudborough he pointed out that only in the case of yeast could a culture be made from a single selected cell. In plate cultivations made from sufficiently diluted mixtures containing only one or two species, he thought one might safely presume that the bacteria from a single colony of such a plate had sprung from a single cell. The macroscopic appearance of the colonies often helped one to decide.

He referred him to their previous paper for the tests used to show what acids were present; they never attempted to prepare the pure acids. With regard to the gases, the volume of air in the flasks and connections amounted in one case to 50—60 c.c., in another to 100 c.c., whereas the volume of gas collected was 3,000 c.c. The gases from the first two days were rejected as containing air. The amount of N was greater on the 39th day than on the 8th day. They could not explain the variation in the amount of oxygen; they simply gave their results and made no attempt to theorize.

Dr. CLOWES wished, as this was the last general meeting of the Section at which Mr. Carulla would preside as Chairman, to acknowledge, on behalf of the members, their indebtedness to Mr. Carulla for his devotion to the interests and development of the Section, as well as of the general Society. By his constant presence at all their meetings, his courtesy and kindness to all, and his development of the movement for extending the membership of the Section in the Midland towns within reach of Nottingham, Mr. Carulla had rendered the term of his office memorable.

The CHAIRMAN said that as this was the last meeting of his term of office he would like to remark on the success that had attended the experiment commenced two years ago, of fixing the dates for meeting at the beginning of each Session, and trusting for papers to the good offices of the members as the months came round, irrespective of any promises when fixing the dates. It was true that they had in Dr. Clowes a reserve, or tower of strength, but as a matter of fact, although he had read several papers in the ordinary way, they had only been compelled to call on him in an emergency on one occasion. He (the Chairman) therefore heartily thanked all the readers of papers, and would only add, in conclusion, that much of the success of the past two years was due to the courtesy and diligence of their Hon. Sec., Mr. J. T. Wood. It had been a pleasure to work with him from the very commencement when they were both new to their respective offices. He was bound to express the conviction that, high as was the standing of the Society of Chemical Industry at the present time, it would be carried still higher by officers so courteous and devoted to duty as was their Hon. Sec. He heartily thanked Mr. Wood on behalf of the whole Section.

## NITRIFYING ORGANISMS.

BY JOHN GOLDING.

(*Lecturer in Agricultural Chemistry, University College, Nottingham.*)

Mr. JOHN GOLDING exhibited a series of lantern slides, photographs, water cultures and microscope slides illustrative of the assimilation of nitrogen by leguminous plants.

Mr. Golding having referred to Dr. Voelcker's paper before the London Section, went on to say that the lantern slides which he (Mr. Golding), was exhibiting were taken from plants grown at the University College, Nottingham, in pots of pure quartz sand, which pots had received only pure chemicals as food.

These slides comprised all the commoner farm crops photographed at the flowering stage. Abundant growth was shown where a complete manure containing nitrogen, phosphorus and potassium, had been added, while in the case of the cereals, rye grass, and other non-leguminous plants starvation to a more or less marked degree was demonstrated when any one of these constituents was omitted. With the leguminous plants, however, it was shown that the pot which received no combined nitrogen thrived well, providing there were plenty of nodules produced on the roots.

Mr. Golding's pots of sainfoin and lucerne had failed to produce nodules though grown under precisely the same conditions as the clover, peas, and beans which were abundantly noduleated. They were, however, afterwards fertilised by being taken for exhibition purposes to Leicester.

Mr. Golding suggested that where new crops were grown in any neighbourhood the "nitragin" fertilising material should be tried.

Photographs were shown of two bean plants grown in sterile sand, in the absence of combined nitrogen, all other constituents of plant food being added. One plant was fertilised and showed abundant growth, while the other which was not fertilised had no nodules formed on the roots and was very stunted and unhealthy. The water cultures exhibited showed nodules on the roots of gorse, laburnum, clover, alsike, peas, beans, and vetches. The difference in the appearance of the nodules was very apparent. The microscope slides and micro-photographs shown, illustrated the difference in appearance of the organisms when taken direct from the nodules which they inhabit. Mr. Golding pointed out that so far as his experiments had gone, this difference vanished when the organisms were cultivated on artificial media, though they still apparently retained the power of fertilising only those plants very nearly allied to the kind from which they were obtained.

## New York Section.

The following have been elected to fill the vacancies, and will take office in July next:—*Vice-Chairman:* T. J. Parker. *Committee:* H. Clementson, W. D. Horne, G. A. Prochazka, Clifford Richardson, and G. W. Thompson.

Meeting held on Friday, May 21st, 1897.

PROF. CHAS. F. CHANDLER IN THE CHAIR.

## THE PRESENT STATUS OF THE HYOSCINE-SCOPOLAMINE QUESTION.

BY LOUIS MERCK, PH.D.

HYOSCINE has been an object of active controversies, more so, probably, than any other one of the notable alkaloids. These controversies, after apparently becoming dormant for a time, have again and again sprung up and engaged scientists of note on opposite sides.

It was from the so-called amorphous hyoscyamine, the mixture of bases obtained from hyoscyamine seeds, that Ladenburg first isolated a substance to which he gave the name of hyoscyne. The same discoverer assigned to the newly-found base the formula  $C_{17}H_{23}NO_3$ , thus claiming it as an isomer of atropine and hyoscyamine. Hesse, on the other hand, contended that the new base was possessed of the composition  $C_{17}H_{21}NO_3$ . He also declared it to be identical with the substance which E. Schmidt had isolated from scopolia atropoides and which had been named scopolamine. Subsequently, E. Schmidt found the hyoscyne-hydrobromate of the markets to consist almost exclusively of the hydrobromate of scopolamine. He does not, however, consider the non-existence of a hyoscyne  $C_{17}H_{23}NO_3$  to be thereby demonstrated. He argues in favour of the possibility that a base of such composition may indeed occur in the mixtures of alkaloids obtained from the solanaceae; that Ladenburg had actually got hold of that base, which gave him the data for his formula and description of what he called "hyoscyne"; and that the same base has since then happened to be isolated again.

Be that as it may, the "hyoscyne" put upon the market by E. Merck has been and is assuredly identical with scopolamine. It is only for the purpose of obviating misunderstandings in commercial and medical circles, where a change of name is apt to create great confusion, that our house has retained in its trade-list the designation of "hyoscyne" for the base from hyoscyamus, while applying that of "scopolamine" to the base from scopolia atropoides. Since the opening of this controversy the Merck laboratories have, in working considerable quantities of the solanaceous drugs for alkaloids, steadily been directed toward the object of identifying a base  $C_{17}H_{23}NO_3$ , which is to possess the properties of hyoscyne. So far, however, we have not succeeded in isolating such a base.

In the course of these labours we were indeed fortunate enough to isolate a base  $C_{17}H_{23}NO_3$ , thus isomeric with hyoscyamine and atropine, from duboisia myoporoides. This base we have named "pseudo-hyoscyamine." Its properties, however, differ essentially from those known for hyoscyne. For instance, hyoscyne is an oily liquid, while pseudo-hyoscyamine melts at about 132° to 134°. Thus, the possibility of any confusion between these two appears wholly excluded. The base isolated from Duboisia myoporoides by J. Gadamer (albeit in quantity insufficient for exact determination) is equally unlikely to represent Ladenburg's "hyoscyne," inasmuch as Gadamer, from his analytic results, concludes that it contains but 15 atoms of carbon. Our own investigations at the works covered these solanaceous drugs: Belladonna, duboisia, datura, stramonium, hyoscyamus, scopolia.

On examining even very large quantities of the bases residuary from the manufacture of atropine, we have so far encountered no substance which would even approximately be capable of identification with the "hyoscyne"  $C_{17}H_{23}NO_3$ . Furthermore, repeated efforts were made by us to isolate all the alkaloids from duboisia. All that was obtained on such occasions was: hyoscyamine, hyoscyne (or scopolamine)  $C_{17}H_{21}NO_3$ , considerable quantities of amorphous bases, and pseudo-hyoscyamine. Never was an alkaloid met with in this work answering to the formula given by Ladenburg for hyoscyne, and at the same time possessing its characteristic properties regarding salts and double salts—properties which would have rendered such an

alkaloid incapable of being overlooked. The same negative result was had from investigation of the alkaloids of stramonium seeds, which, likewise, were worked in quantities of thousands of kilogrammes. The Merck laboratories are also continually working for alkaloids, large quantities of hyoscyamus seeds, and scopolia roots. Also in these lines of manufacture we constantly kept our attention directed toward isolating the alkaloids occurring among the residuary bases. Nevertheless, the search for the particular base here in question has proved equally fruitless on these two drugs.

In this connection I may be pardoned the liberty of alluding to still another interesting fact developed at our laboratories. The statement is frequently met with in literature, that hyoscyne (that is, scopolamine) has been isolated from the residual bases obtained in the manufacture of atropine. Therefore, it might readily be inferred that hyoscyne is a side-base to hyoscyamine or atropine in the belladonna. We have studiously kept this issue in view during the working of many hundreds of thousands of kilos of belladonna roots. And still we have never been able to discover hyoscyne (meaning scopolamine) among the residual bases resulting from these extensive operations. This experience of ours thus directly contradicts the inference before mentioned. The experiences of others, as quoted before, may be presumed to have been due to defective sorting of the belladonna roots, among which may have remained roots of other solanaceae. Or, the residues remaining from the manufacture of various solanaceous alkaloids, and utilised for obtaining side-bases, may not have been kept absolutely apart.

It may be contended that, in the Merck researches, the hyoscyne or scopolamine that might have been present could have been overlooked in consequence of its own minimal quantity. This contention, however, is met by the fact that the mixtures of residual bases were, at the end, also subjected to splitting; whereupon the appearance of scopoline among the products of this operation must have indicated that hyoscyne had been present, if such were indeed the case. From a single batch, for instance, of residual bases thus treated, 100 kilos. of tropine were obtained, whereas the presence of a higher-boiling base was not demonstrable.

To return, after this little digression, to my main topic, I would once more summarise our laboratories' experiences regarding the latter, to wit: With due consideration of the various solanaceous drugs, and with the use of very considerable quantities of them, the results so far have failed to show the possibility of obtaining a base possessing the properties of hyoscyne and answering to Ladenburg's formula of  $C_{17}H_{23}O_3$ . Thus, this whole question has, by this time dwindled down almost exclusively to a controversy between O. Hesse and E. Schmidt as to the propriety of designating the surely-established alkaloid  $C_{17}H_{21}NO_3$ , either as "scopolamine" or as "hyoscyne."

The polemics between the two investigators named have, however, recently extended into still another chapter of the solanaceae-alkaloid research, which bears close relations to the one I have here discussed. O. Hesse published an observation made by him in the scopolamine hydrobromate of commerce, to this effect:—He frequently found this salt to contain also notable quantities of another base, differing from scopolamine by the absence of optical rotatory power. This would, of course, have the result that such a mixed salt would show a smaller area of rotation than that due to the pure scopolamine hydrobromate.

He succeeded in isolating this inactive base, and gave it the name of "atroscine." Hesse argues against any supposition of identity as between his "atroscine" and the so-called "inactive scopolamine," found by E. Schmidt. His reasons herefor are two:—Firstly, he did not succeed in obtaining, by the treatment of hyoscyne with alkalis, an inactive base of equal composition. Secondly, he claimed on the other hand, that the decrease in optical activity resulting in hyoscyne upon treatment with alkalis is due altogether to a splitting of the hyoscyne into a "split-base" which he calls "oscine," and tropic or atropic acids. O. Hesse's "oscine" is stated as being identical with E. Schmidt's split-base "scopoline."

E. Schmidt, again, gives the genesis of his "inactive scopolamine" as being likewise brought about through the action of alkalis on scopolamine; with the additional statement that it can also be produced by using silver oxide instead of the alkalis. He states that he never encountered any "atropine" in the process of isolating alkaloids from commercial scopolia roots or hyoscyamus seeds. Schmidt further explains that accordingly as the liquors from scopolia root are treated with less or more intensively-acting alkalis one may obtain at will either a normal scopolamine (rotating about 24 to 25°), or a feebly-rotating one. He succeeded even in directly obtaining, from one and the same scopolia root, a normally (that is, strongly) rotating and a feebly-rotating scopolamine. The former was obtained by alkalinising the liquors with sodium bicarbonate or ammonia; the other by employing strong bases, such as soda-lye, concentrated solution of potassa, &c.

It is thus still an open question, whether or not Hesse's "atropine" should be regarded as identical with Schmidt's "inactive scopolamine." Upon considering the contradictory verdicts of medical authorities who have tested both these substances as to their action on the eye, one might almost incline toward the second alternative; that is, non-identity.

O. Hesse, in his treatise, quotes medical councillor Dr. Königshofer's conclusions from physiological tests made by him with atropine, to the effect that its action differs in certain points from that of scopolamine. The passage quoted reads as follows: "We thus find that this remedy" (that is, atropine) "acts identically with atropine and scopolamine, in so far as its mydriatic effect is concerned; while in the matter of paralysing the accommodation it considerably surpasses both these substances in promptness of action as well as in duration of effect; the ratio of difference ranging from double to quadruple."

E. Schmidt, on the other hand, reports that Prof. Dr. Uthoff, Director of the Eye Clinic at the University of Marburg, in conjunction with Dr. Axenfeld, Lecturer, arrived at the following important conclusion:—In comparative tests with a strongly rotating scopolamine hydrobromate (25.43°) and a very feebly rotating salt (6.62°), "..... it was found that no difference whatever could be shown between the effects of these two salts."

To these contradictory reports published by Schmidt and by Hesse, I can add the following facts gathered from observations made by us at the Darmstadt Laboratory. Ever since this property of hyoscyne, of strongly rotating the plane of polarisation, has been known, special regard has been given to this point at our laboratories in working the side-bases from hyoscyamus seeds for hyoscyne. The product of each separate batch was invariably examined for the determination of its optical properties. In the course of these observations it was found that we always obtained a hyoscyne of normal rotatory power with but very slight variations, that is, ranging between about 24 and 25 degrees. We have been unable so far to discover a feebly rotating preparation obtained from hyoscyamus seeds.

In the manufacture of scopolamine from scopolia roots, we made the optical rotatory power a subject of special research only quite recently; and in consequence I can give you the results only on an amount of scopolamine obtained from about 16,000 kilos. of the roots. The scopolamine hydrobromate from this quantity, on being crystallised, was shown to be absolutely pure, but to possess a *lævo*-rotatory power of only 13.47°.

In connection herewith I should state that, in working the scopolia roots and in working up the side-bases for scopolamine, exactly the same stages were adhered to, as in working the hyoscyamus seeds and in working up their side-bases for hyoscyne. Especially in the manner of using alkali in both series, the most punctilious care and attention were exercised in order to make the conditions in both exactly equal. Hence, I cannot well refrain from the conclusion that the alkali can hardly have caused the difference in rotatory power in these cases of ours; for, had it done so, a more feebly rotating product must have resulted in the isolation of the hyoscyne as well as in the other case. This experience seems to me to argue largely

in favour of O. Hesse's view, that two chemically equal basic substances, which so far can be distinguished from one another only by their optical activities, are contained in the ordinary scopolamine hydrobromate; and that, quite possibly, they exist performed already in the scopolia root.

The few observations so far available cannot, of course, suffice to settle the pending controversy. But it affords me gratification to be in a position to promise the early publication of further results from considerably larger batches of scopolia roots, in which likewise the various results will be most carefully noted; which, I hope, may contribute toward the further elucidation of this question.

## THE MANUFACTURE AND APPLICATIONS OF LACTIC ACID.

BY ALAN A. CLAFFIN.

THIS paper consists of extract from notes on observations taken during seven years' experience in the manufacture of lactic acid on a large scale on lines laid down by my predecessor, Mr. Chas. E. Avery. While some of my facts are not new, considerable work having been done very recently on this subject; and while none of my investigations have been carried farther than the daily exigencies of manufacture required, yet I trust that from the exceptional opportunities that I have had, they may be found of interest.

The lactic acid industry dates back about 20 years, when Mr. Avery began his investigation, which resulted in the process which he covered from 1881 to 1885 by American and foreign patents. The production of lactic acid on a large scale by fermentation is interesting because it employs micro-organisms to split up the glucose molecule into two molecules of ethylidene lactic acid. The micro-organism that does this work is well-known as the *bacillus acidilactici*. This bacillus has been described variously. Not from any inaccuracy of the observer, but because it is of great variety itself, a certain variety developing most rapidly in a certain medium. The bacillus which does the work in a highly nitrogenous saccharine solution is a large species. Its form is a double truncated cone, averaging in length 2 to 2½ mm., and about 1 mm. in diameter. It has the tendency of all lactic bacteria to link itself together in pairs or short chains. The most abundant lactic bacteria in sour milk are only  $\frac{1}{10}$  mm. long, but a little thicker in proportion than those found in my saccharine solutions.

The manufacture of lactic acid has three divisions:—The preparation of the saccharine solution, the fermentation, the conversion of the fermented liquor into commercial lactic acid. The source from which the saccharine solution is obtained is not important. The location of the factory determines the raw material that can furnish a glucose liquor most cheaply. The proportional composition of the saccharine solution is very important. For complete decomposition the saccharine solution should not vary between the limit 1.05 to 1.075 sp. gr.: for technical reasons the higher density is preferable. A solution of that density will contain from 7½ to 11 per cent. of saccharine matter. It is not essential to have all the saccharine matter in the form of grape sugar. In fact, it seems to be advantageous to have 10 to 15 per cent. of it as cane-sugar, which becoming inverted in the process, furnishes fresh material, as it were, for the ferment. To do its work thoroughly, the lactic bacillus needs be well nourished by nitrogenous matter. The most convenient form for this nitrogenous material is as it comes from vegetable life, as extracted, for instance, from bran by the action of boiling water and dilute acid. At different times I have used material obtained from animal and mineral sources. In the laboratory it is difficult to detect material differences. On the large scale, I prefer a vegetable source; there seems to be a complete utilisation of the material. The amount of nitrogenous material should be at least 8 per cent. of the saccharine constituents. I assume by nitrogenous matter a body of substantially the composition of albumin containing 15 to 20 per cent. of nitrogen in complex form. Perhaps it would be more accurate to say the total nitrogen should be nearly 2 per cent. of the saccharine material, and preferably combined

with carbon. If a mineral food is to be employed, ammonia salts should be in larger proportion than nitrates. A low percentage of phosphates will suffice, and the presence of much potassium does not seem to be essential.

The requisite saccharine solution made up and boiled for at least an hour, to make sure of sterilisation, is conveyed into the fermentation tank. There it is rapidly cooled to 55° C. or lower, not going below 45°, and impregnated. Impregnation takes place at a higher temperature than observers have generally stated, a peculiarity perhaps arising from the large scale at which the work is carried on. I may state here, in a general way, that the modified conditions caused by working the bacteria on a large scale, give an opportunity for variation from laboratory results. A large body of fermentable liquor is less susceptible to foreign spores, more energetic in its development, and productive of more obvious results than a solution such as is usually found in the laboratory. Consequently I feel that the chemist, who is to investigate and utilise, to the fullest extent nature's great oxidising agent, the mycoderma aceti, and nature's great reducing agent, the bacillus butyrici, must be as familiar with them in a 5,000 gallon vat as in the pure culture state in a test tube.

In continuous manufacture the ferment solutions are impregnated from a pre-ceding ferment liquor, in which a lively fermentation is in progress. Decided advantage is obtained by using a generous amount of such liquor. 20 per cent. is none too much. For an original impregnation, lactic bacteria must be obtained from an outside source. I prefer to use for that source, milk that has been allowed to stand at a temperature of 45° until slightly sour. If the milk is allowed to sour too long, before using as an impregnating fluid, a tendency is shown for butyric bacilli to develop. This same objection is true if rotten cheese is used. Should the saccharine solution be allowed to ferment spontaneously, everything may happen or nothing. A good lactic fermentation may develop, a meagre alcoholic, or a meagre viscous, a little butyric, or a little of each, and very much butyric, the last of which is most probable. The best original impregnation I ever had was obtained in the following manner:—A pure culture of the lactic bacillus was obtained from the bacteria in a ferment tank, and preserved. Previously sterilised milk was impregnated from this culture, and kept under pure culture conditions for a day, and then used with noticeable advantage over the spontaneously soured milk.

The impregnation accomplished in the saccharine solution, which should be neutral or faintly acid, not alkaline, the main process in the manufacture of lactic acid is begun. The success or failure in the manufacture depends wholly in the management of the fermentation. For economical production, over 90 per cent. of the glucose must be converted into lactic acid. Any unconverted glucose works a double injury, not only being a loss of material, but also making the resultant lactic acid liable to subsequent decompositions. In our factory to-day we have practically no residue of undecomposed glucose, and the yield of lactic acid is over 98 per cent. As I have said before, the impregnation takes place at 45° or above, and from that point the temperature is allowed to decrease somewhat as the fermentation solution grows older. If it is desirable, as it usually is, to have the fermentation proceed briskly, the temperature must be higher than when, as is occasionally the case, it is desired to have a slow fermentation. It should be borne in mind, however, that a lactic fermentation of itself gives out considerable heat; the more so if quick running. As the fermentation progresses, the solution must be neutralised with milk of lime, or chalk in suspension. The limits of acidity in which lactic bacteria are healthy are rigidly confined between 0.02 and 0.5 of 1 per cent. Keeping the acidity of the fermentation between these limits is the main preventative against butyric fermentation, as the regulating of the temperature is the preventative against alcoholic fermentation. If the fermenting solution is over neutralised, the butyric ferment will at once begin to act, and once active is very difficult to control. It is the greatest enemy to the lactic fermentation, destroying the lactic acid that has been made, and devouring new quantities as fast as they can be pro-

duced. In 24 hours one-third of the lactic acid may be destroyed by the butyric bacillus. Anti-ferments cannot be used with much safety in lactic fermentation. The lactic bacillus is more susceptible than other ferments, and is killed while others are only stagnated. Mustard-seed oil is about the only exception that I know. This has apparently a deadening effect on butyric fermentation, with no serious effect on the lactic fermentation. The lactic fermentation is best completed in from three to six days, although its life may be prolonged up to a fortnight. Any prolongation of life is attended with the danger of butyric invasion. When the fermentation is ended, the liquor must be heated sharply to kill all bacteria and spores and prevent subsequent fermentation.

The fermented liquor, which is now a solution of calcium lactate, with a multitude of dead lactic bacteria floating in it, is filtered and evaporated. If a pure lactic acid is desired, the calcium lactate is allowed to crystallise and purified by repeated crystallisation. For a commercial lactic acid, decomposition by sulphuric acid of the dense uncrystallised solution of calcium lactate gives an acid of sufficient purity. The free acid obtained from this decomposition is further concentrated to such strength as the market demands. In evaporating free lactic acid there is danger of forming lactic anhydride. It is possible to have conditions such that the longer evaporation takes place the less percentage of lactic acid is obtained. In concentrated solutions, very little lactic acid is lost by volatilisation. In dilute solutions much acid may be mechanically carried away with steam, especially if a blast is used. A 50 per cent. solution is about as concentrated as it is economical to manufacture. This appears on the market as a syrupy liquid, with more or less brown colour, and a specific gravity of 1.20, and contains about 7 per cent. lactic anhydride.

The applications of lactic acid to-day, while limited, are increasing. The majority of all that is produced is used by the woollen dyer as an assistant in mordanting with bichromate of potassium. For this purpose I believe it has advantages which the technical world is beginning to appreciate. Without discussing at length the comparative merits of tartaric, oxalic, and lactic acids, I will just mention the advantages which are claimed for lactic acid, namely, greater reducing power, greater solubility of itself and its salts, and less corrosive action. The first claimed advantage the greater reducing power of lactic acid towards chromium salts and chromic acid, is generally admitted in comparison with oxalic acid, and also in the case of tartaric acid, although the fact that tartaric acid reduces chromium salts more quickly, has led to some discussion. Admitted that lactic acid has the greater reducing power, the value of this property in the dye-bath is not yet absolute, as with many colouring matters I do not find that the best results are obtained with the chromium reduced to its lowest terms. Yet, if lactic acid does the most economical reducing, it is but a question of correct proportioning of the recipe, to obtain the desired shade at the lowest cost. The second and third advantages—greater solubility and less corrosive action—are unquestioned. In corroboration of my estimate of the value of lactic acid in the woollen industry, the following statistics of lactic acid are submitted. In 1894 the dyehouses of the United States and Canada used about 100,000 lb. lactic acid, while none was used in England or Europe; in 1895 there was a domestic consumption of 1,000,000 lb., and a foreign consumption of 500,000 lb.; in 1896 the domestic consumption was 1,200,000 lb. and the foreign 1,000,000 lb.

Lactic acid is used to a very limited extent in the calico printing industry. Some discharge effects can be obtained advantageously with it. In most instances, however, the hygroscopic nature of the acid is injurious in its effect on colours which have to be steamed.

Next to the woollen industry the most important application for lactic acid is in the preparation of hides for tanning. The efficiency of the bran drench for removing the lime from the skin, and making it porous and in good condition for receiving the tannage, is due to the lactic acid produced by the fermentation of the bran. A dilute solution of lactic acid will do this work as well, and is much easier

to control in its action. The slightly higher cost is more than compensated for by the prevention of waste. To the researches of Mr. Wood (J. T. Wood, this Journal, 1885, 27 *et seq.*) and Mr. Andreaseh (F. Andreaseh, *Der Gerber* 21, 506; 22, 513) this application is attributable. In America over 300,000 lb. of lactic acid have been consumed, mainly by a few tanneries, during the last six months.

In the household lactic acid is used medicinally, and is a substitute for other acids and fruit juices in making acid beverages. The large possible application of lactic acid for domestic use—the replacing of cream of tartar by the acid lactate of calcium—has not yet been put in practical operation.

With regard to the analysis of lactic acid, I feel I can add little to what Allen has collected in the latest volume of his *Organic Analysis*, (A. H. Allen, *Commercial Organic Analysis*, Vol. III., Part III., 411 *et seq.*). On account of the solubility of all its salts, the direct determination of lactic acid is a long and delicate process. Generally the indirect method—determining total acidity and percentage of foreign acid—gives most expeditious results. There is not much sophistication of lactic acid. Sometimes acetic and mineral acids are found in it, and now and then samples of so-called lactic acid containing no lactic acid at all. Usually, however, commercial lactic acid is pure, except from products incident to manufacture and not deleterious in effect. The strength varies from 20 to 50 per cent., according to the price and for what purpose the acid is intended to be used.

#### DISCUSSION.

Dr. L. REUTER asked whether ether or alcohol was used to separate the lactic acid from the mixture of calcium lactate and sulphuric acid.

Mr. CLAYLIN said that the bulk of the sulphuric acid was neutralised by the calcium of the calcium lactate, calcium sulphate being practically insoluble in lactic acid. No ether or alcohol was used. The solution of lactic acid was simply evaporated. In reply to a question from Dr. G. A. Prochazka, for percentages higher than 30 per cent. it was advantageous to evaporate *in vacuo*; for less percentages air would do perfectly well. Copper vessels were employed for evaporating.

In reply to a question whether any difference in the fermentation from the amount of electricity in the air was observed, on the principle of thunder storms making milk sour, the author stated he had never noticed any difference, because the ferment solutions were well protected from atmospheric influences and kept at a uniform temperature. Lactic acid made by evaporation had more or less colour according to circumstances. It contained no sulphuric acid or sulphate of lime. Baryta was used to remove any traces of sulphuric acid, although sulphate of lime was very nearly insoluble in concentrated solutions of lactic acid. The temperature employed was about 115° C.

Mr. R. C. WOODCOCK asked in what form the nitrogenous matter, intended to act as food for the bacteria, was added to the solution—whether as ammonia salt or as albumenoid. And what was the final condition of this nitrogen in the solution after the fermentation germ had done its work.

Mr. CLAYLIN said the nitrogen seemed to be taken up by the ferments themselves; for when, after fermentation, the solution was filtered and the dead bacteria collected and analysed, there was as much nitrogen in them as in the original solution.

The CHAIRMAN said that some interesting investigations had recently been made in Boston with regard to the bacteria in milk, and it was found that by the use of special precautions milk free from bacteria could be drawn from the udder of the cow, showing that the milk in the cow was free from bacteria, but in the process of milking became impregnated. The cow was covered with dust, which was full of germs, so that in the ordinary course the milk in the pail became impregnated as soon as it was drawn from the cow, and in many cases more bacteria had been found in milk as delivered than there were in an equal quantity of sewage, the milk favouring the rapid development of the bacteria.

## THE DETECTION OF ARSENIC AND ANTIMONY, EITHER ALONE OR IN MIXTURE.

BY P. H. CONRADSON.

IN 1889 there appeared in the "Druggists' Circular and Chemical Gazette" an article setting forth the sensitiveness of the well-known Hager's silver nitrate test for arsenic (evolution of arseniuretted hydrogen) with zinc and dilute sulphuric acid, letting the evolved gas act upon filter-paper moistened with nitrate of silver solution. If arsenic is present the silver paper blackens. Although the nitrate of silver paper is all that can be desired as regards delicacy for arsenic, still the test in the presence of sulphur and antimony is not certain, neither does it fully decide whether antimony might be absent or present. On this ground I set about to devise a simple test for the detection of antimony, whether alone or in mixture with arsenic. After a good deal of study on the subject, I found the following indicator, or test paper (which I will call "nitro-iodine paper") to work very satisfactorily indeed.

The material to be tested for arsenic or antimony, or both—such as colours, paper-hangings, fabrics, or other organic or inorganic matter—is treated, according to Hager's method, with concentrated solution of soda nitrate, dried, and burnt upon a porcelain saucer, residue boiled with potash solution in excess, filtered, and acidified with dilute sulphuric acid, treated with permanganate of potash, to destroy any organic matter that still may be present; or the material to be tested may be treated in any other suitable or well-known manner to insure the solution of the arsenic and antimony compound.

After the material to be tested has been dissolved in sulphuric acid, the following procedure and precautions have been found to work satisfactorily:—

Four test papers are used, freshly prepared and still moist. Nos. 1, 2, and 3 are prepared by placing a drop or two of lead acetate, silver nitrate, and mercury chloride solutions respectively on the middle of a piece of filter paper, large enough to cover the test-tube. No. 4 is prepared by putting two drops of nitric acid (sp. gr. 1.20) on the middle of a piece of paper, allowing it to spread, and then placing two drops of potassium iodide solution (1 in 10) on the middle of the nitric acid spot. All these test papers should be prepared just before using, and in order, as described later on.

The apparatus used is an ordinary test-tube, about 8 ins. long and  $1\frac{1}{2}$  ins. in diam., with some cotton, granulated zinc (free from sulphur, arsenic, and antimony), and dilute sulphuric acid (also free from arsenic and antimony). In place of the granulated zinc, pure magnesium ribbon can be used with great satisfaction.

The test is made as follows:—Put some of the pure zinc in the test-tube, add some dilute sulphuric acid, insert a loose cotton plug, and lay test paper No. 1 (lead paper) on the top of the test-tube. If the paper does not become dark coloured after 10 to 15 minutes the zinc is free from sulphur, or if the paper should darken somewhat after, say, 5 minutes, then take a fresh paper from time to time until the lead paper is not coloured. I have found that zinc containing a little sulphur may give quite a strong reaction at first, but after 5 to 10 minutes it hardly shows any sign of sulphur. Of course, should the generated hydrogen after 15 to 20 minutes still show a reaction for sulphur on the lead paper, the zinc or acid, or both, are unfit. As soon as no reaction on paper No. 1 is shown, the silver paper No. 2 is inserted; should no coloration take place after 15 minutes, the zinc and the acid may be considered all right for most cases.

Of course if the acid and zinc are known to be free from sulphur and arsenic, the above preliminary tests can be omitted; however, it is always advisable to make these two preliminary tests, as I have found from experience, using granulated zinc, that some lumps are free from sulphur and arsenic, and others from the same lot contain these impurities.

Now some of the suspected material in solution is added, but not too much at a time. The gas should never be generated too fast, or the papers will not give so distinct shades or colours. Then insert test paper No. 4. If no reac-

tion appears, the material is free from sulphur. Then insert No. 2 silver paper. If there is no coloration, even after some time (15 to 20 minutes), the material is apparently free from arsenic and antimony. Should a coloration appear on the test paper, then either arsenic or antimony, or both, may be present. In that case remove the silver paper and insert paper No. 3—the mercury chloride paper. If arsenic alone be present, a pure lemon-yellow spot appears, which gradually deepens to a pale yellowish-brown colour. This reaction has to be watched carefully, as the yellow colour disappears rather fast if too violent generation of the gas is allowed, or much arsenic should be present. Antimonimuretted hydrogen produces on this paper a brownish-grey spot, or colour with no yellow in it and quite distinct from the arsenical coloration. If no yellow colour should appear on this paper at first, but a grey or brown colour without any yellow tint, especially round the border of the moistened paper, arsenic may be considered absent, but antimony is probably present.

Of course it should be borne in mind that the test with each paper should at least continue 15 minutes, with a rather slow rate of evolution of gas. If it has taken 10 or 15 minutes to show a coloration on the silver paper No. 2, in case there should be no coloration of any kind after 15 minutes on the mercury chloride paper No. 3, it will be advisable to add to the test-tube a small quantity of the solution to be examined. It is, therefore, advisable to start with quite a quantity of granulated zinc.

After applying the mercury chloride paper, if no coloration appears or a clear lemon-yellow coloration, antimony is probably absent. To positively verify the absence of antimony, apply test paper No. 4—the nitro-iodine paper, prepared as above described. If antimony is present, first a clear bright yellow colour is produced on the paper, which sometimes darkens to deep yellow, with appearance of orange crum coloured spots on the edges; this reaction is very distinct and characteristic for antimony. Arsenic does not interfere with this colour produced by antimony on paper No. 4, neither does pure hydrogen. The bluish colour, or tint produced when potassium iodide comes in contact with nitric acid on the paper, disappears before the yellow colour is produced by the antimony.

If magnesium ribbons are used in place of granulated zinc, it is very easy to regulate the amount of gas generated, simply by dipping the ribbons to a greater or less extent into the acid solution.

#### RECAPITULATION.

##### *Colours Produced on the Different Test Papers.*

No. 1. Lead paper.—Sulphur produces brown to black colours.

No. 2. Silver paper.—Arsenic or antimony, brown to black tints.

No. 3. Mercury paper.—Arsenic, yellow to yellowish-brown.

No. 3. Mercury paper.—Arsenic and antimony, varied tints, yellowish to brown.

No. 4. Nitro-iodine paper.—Arsenic, no colour.

No. 4. Nitro-iodine paper.—Hydrogen, no colour.

#### DISCUSSION.

The CHAIRMAN said that when he had had occasion to make tests for the detection of arsenic and antimony he had always preferred to pass the gases given off by zinc and sulphuric acid into a solution of nitrate of silver. The arsenic went into solution, precipitating metallic silver, and the antimony formed antimonide of silver, which went to the bottom as a precipitate. This made a complete separation, giving a solution containing arsenic and a precipitate containing antimony, which, upon filtration, gave the antimony on the filter and the arsenic in the filtrate. One had only to cautiously neutralise the filtrate by dilute ammonia to get a yellow precipitate of arsenite of silver; and, after washing the black precipitate of silver and antimonide of silver, and boiling it up with a little tartaric acid and a few drops of hydrochloric acid, a solution of

antimony was obtained, which immediately gave a beautiful orange precipitate with sulphuretted hydrogen. Thus, one saw the products in the form of yellow arsenite of silver and orange sulphide of antimony. He liked to see the precipitates, because one then got a tolerable idea of relative proportions.

#### NOTE ON TURPENTINE OIL AND ITS SUBSTITUTES.

By F. H. CONRADSON.

A TURPENTINE oil was received, called "wood turpentine." It was clear, perfectly water-white, with an odour towards terebene. Its specific gravity was 0.845, flashing point below 80° F., burning point 94° F., and on evaporation left nothing—at least, nothing resinous. From the low specific gravity and low fire-test, it was apparently not pure oil of turpentine, but a mixture of either rosin spirit or benzine, or both, with ordinary oil of turpentine.

Distillation, according to Allen, was tried, and the distillate repeatedly treated with sulphuric acid according to Allen's direction; but I could not separate the fractional distillates in such a way as to distinctly say whether all the impurity or adulterant was rosin spirit or benzine (kerosene).

On treatment with sulphuric acid ( $H_2SO_4$ ) the spurious turpentine became heated only a few degrees after vigorous agitation; on the other hand, pure turpentine, and also so-called fernoline turpentine, heated very considerably, and had to be cooled down with water. This difference in rise of temperature confirmed the belief that the oil in question was a mixture. Allen's test with castor oil was tried, both with pure oil and mixed oil (turpentine and benzine), but no separation took place.

Nothing definite could be made of the permanganate test. I happened to shake some rosin spirit I was distilling with a strong solution of  $SO_2$  in water, and found that the rosin spirit was immediately coloured a beautiful yellow, the aqueous layer beneath being clear. I tried the same with pure turpentine oil, and this oil did not colour at all, or only slightly. The wood turpentine was next tried, and gave the same yellow colour as the rosin spirit. Benzine, gasoline, and 160° oil gave no coloration. With fernoline turpentine considerable heat was evolved, and on shaking a white emulsion was formed, which, on standing, separated into a brownish under layer and a yellowish-white upper layer. This sample of fernoline turpentine had been in the laboratory about eight months in a partly-filled bottle, often open. When the oil first came it left, on evaporation, less than 0.75 per cent. of residue, but now leaves a considerable amount of sticky residue, showing that it has undergone partial oxidation.

This yellow colour produced by  $SO_2$  on rosin spirit, and not on pure turpentine, may be recorded. Further, some rosin was dissolved in the pure oil and treated with  $SO_2$ ; about the same coloration occurred as in the rosin spirit.

The spurious turpentine and the rosin spirit in  $SO_2$  water treatment, after standing several hours, commenced to change colour on the surface, namely, brown towards blue; and on standing over night, the yellow colour was gone, and the liquid had become a reddish to a bluish-brown. The pure turpentine did not perceptibly change its first appearance. The turpentine to which rosin had been added did not change colour, but in the main kept its yellow colour.

A sample of pure turpentine oil, water-white, clear, and leaving on evaporation only a small residue (Standard Oil Co.'s make), has a specific gravity of 0.870; other sample, one of 0.867. Flash in open cup, 100° F.; burn, 110° F.

A mixture of turpentine oil of 0.870 sp. gr., volume 90 per cent., and 150 oil of 0.794 sp. gr., volume 10 per cent., gave 0.861 sp. gr.

A mixture of turpentine oil of 0.870 sp. gr., volume 90 per cent., and benzine of 0.748 sp. gr., volume 10 per cent., gave 0.8544 sp. gr.

The mixture, with 10 per cent. of benzine, flashed at the ordinary temperature (70° F.), so if 10 per cent. or more of naphtha or benzine is present, the lower specific gravity as well as low flashing point is sufficient indication of

adulteration (if no rosin spirit should be present). The flashing point of the mixture with 150 oil would, of course, be as high, or higher, than for pure oil of turpentine.

There are several tests given from time to time for the detection of petroleum oil in oil of turpentine, and the following one, in addition, may be of some use because of its simplicity, as well as snooty, for a qualitative test at least. Pure oil of turpentine, say 50 c.c., is evaporated down to 1 or 2 c.c. on a water- or steam-bath; the residue (usually rather thick) carefully poured into a perfectly dry test-tube, and from 5 to 10 c.c. pure acetic acid (glacial) 99.5 per cent. used in the test, and the mixture shaken. If the oil be pure the liquid remains perfectly clear, no separation taking place. If the oil contain as small an amount of kerosene as 10 per cent., the mixture, on shaking, becomes cloudy or milky, and on standing for an hour or more, the petroleum separates on the top. Glacial acetic acid (99.5 per cent.) dissolves a mixture of turpentine oil and petroleum oils very readily up to 30 or 40 per cent. of adulterant, hence the necessity to evaporate the turpentine oil down to the prescribed volume (see this Journal, 1890, 1005).

#### DISCUSSION.

Mr. G. W. THOMPSON said there was a recent communication in one of the Journals referring to the presence of oxidation substances in turpentine, having the nature and reactions of aldehyde, which could be removed by treating the turpentine with an alkaline sulphate or bi-sulphate. Something similar to that reaction might take place in the author's treatment of the rosin spirit, or oil containing rosin spirit, with sulphurous acid. He himself had wished to make use of the test referred to in the communication, by treating turpentine with an alkaline bi-sulphate, but had been unsuccessful. If anyone present could offer any suggestion on that point he would be very much obliged, because in the use of turpentine for varnishes there were very peculiar reactions between turpentine and manganese salts. For instance, if oleate of manganese, as pure as they could make it, were added to ordinary turpentine the solution became heated and darkened in colour. There seemed to be some oxidation of oleate by the turpentine. They knew turpentine had the power of absorbing ozone and oxygen, and in this case it seemed to give it up to the manganese. He wanted to find out if it were an aldehyde substance that produced this action.

Mr. WOODCOCK said that if the oxidation of turpentine were carried on at about 120° F., after the turpentine had absorbed certain quantities of oxygen, there were large quantities of camphoric peroxide formed. That was a very peculiar product, inasmuch as under certain conditions it decomposed, giving off peroxide of hydrogen, and leaving a residue consisting chiefly of soluble camphor.

#### PRACTICAL HINTS IN LIMESTONE ANALYSIS.

BY K. A. SUNDSTROM.

IN manufacturing bicarbonate of soda the writer had to use limestone, varying in composition with every cart load, and it was therefore an imperative necessity to analyse it quickly and correctly. A gas analysis could be made speedily, but gave no idea of the proportions between lime and magnesia, while the limestone should not contain at most more than 5 per cent.  $MgCO_3$ , not over 1.5 per cent.  $SiO_2$ , and only traces of  $Al_2O_3$ . We had to have a complete analysis finished in three hours, and the amount of  $MgCO_3$  should not differ more than 0.25 per cent. at utmost from the right one.

After many different trials and experiments made by my assistant, Mr. H. E. HARRISON, we are satisfied that the following method, if executed as described, will give a correct and satisfactory result. The difference between this method and that of Fresenius, which requires a time of 24 hours, will be found less than  $\frac{1}{10}$  per cent.

*Selection of Sample.*—Take pieces about 1 lb. in. in size from different parts of the bed, pile, or shipment to be

tested. Pulverise the whole sample to pass through a 900-mesh wire sieve. Mix well, spread out in a layer, and with the point of a spatula take about 10 grms. in small portions from different parts of the layer. Reduce this small sample to an impalpable powder, first in a porcelain and then in an agate mortar.

(A.) Weigh out two portions of 1 gm. each of the finely-powdered sample, transfer to small-sized basins, add to each about 100 c.c. distilled water. To one run in 25 c.c. normal HCl, cover with a watch glass, and allow to stand until all action ceases. Heat to boiling, cool, and neutralise with normal NaHO, using a drop of methyl-orange as indicator. c.c. HCl — c.c. NaHO = HCl required to saturate the carbonates of lime and magnesia.

(B.) To the other portion of 1 gm. add cautiously 5 c.c. concentrated HCl, keeping the basin covered with a watch glass to prevent loss by spurling. After all effervescence has ceased, evaporate to complete dryness over a low flame. When dry, cool and take up with a little hot water and a few drops of concentrated HCl. Heat to boiling and filter through an ashless filter, being careful to wash all insoluble materials into the filter. Wash with boiling water until free from all trace of chlorides.

(C.) Dry the filter and contents and ignite in a platinum crucible to bright redness, cool under desiccator, and weigh for  $SiO_2$ .

(D.) Neutralise the filtrate and washings from (B) with  $NH_4HO$  in slight excess. Heat to boiling, filter and wash the precipitate, if any, until free from chlorides. Dry at 110° C. and ignite; cool and weigh for  $Al_2O_3$  and  $Fe_2O_3$ .

(E.) Heat the filtrate and washings from (D) to boiling and add a concentrated solution of ammonium-oxalate, "also heated to boiling." Allow to stand until settled clear, which is done, if rightly treated, in two or three minutes; decant the clear solution into a filter and dissolve the precipitate in HCl and re-precipitate with  $NH_4HO$ . Allow to settle, decant as before, and then wash the whole precipitate into the filter, and wash with hot water until free from chlorides and oxalates. Dry at 110° C. and ignite in a platinum crucible, at first cautiously, and then over a blast-lamp, until completely converted to  $CaO$ . Cool under a desiccator, weigh, and calculate per cent.  $CaCO_3$  from weight of  $CaO$ .

To check results titrate the  $CaO$  with the normal HCl.

Divide percentage of  $CaCO_3$  by 5 (= c.c. normal HCl required for  $CaCO_3$ ) subtract the quotient from c.c. normal HCl required for (A) and multiply remainder with 4.2 for per cent. of  $MgCO_3$ .

For practical purposes we can recommend this method, and we have successfully used it for the last two years, and in many instances been able to finish a complete analysis in two hours.

Example:—1 gm. stone = 19.85 c.c. normal HCl.

The weight of the ignited  $CaO$  0.538 gm. multiplied with 1.785 = 96.033 per cent.  $CaCO_3$ , the check with normal HCl = 19.2 c.c. and  $19.2 \times 5 = 96.0$ , which corresponds very nicely.

$19.85 - 19.2 = 0.65$  c.c. normal HCl for  $MgCO_3$ .

$0.65 \times 4.2 = 2.73$  per cent.  $MgCO_3$ .

$SiO_2$  weighed = 1.06 per cent. and  $Al_2O_3 + Fe_2O_3$  not present.

Thus the result was the following:—

	Per Cent.
$CaCO_3$ =	96.00
$MgCO_3$ =	2.73
$SiO_2$ =	1.06
$Al_2O_3 + Fe_2O_3$ =	0.00
Difference .....	0.21
	<hr/> 100.00

Direct determination of the  $MgCO_3$  as  $Mg_2P_2O_7$  gave 2.79 per cent.

The CHAIRMAN then announced that the Session was now closed, and that when it reopened in October he hoped to be able to invite the Section to hold their meeting in the new Havemeyer Laboratory of Columbia College.

## Obituary.

### PETER HART.

VICE-CHAIRMAN OF THE MANCHESTER SECTION OF THE SOCIETY OF CHEMICAL INDUSTRY.

PETER HART was born at the village of Orford, near Warrington, on June 6th, 1834. His father was employed in Muspratt's Alkali Works, at Newton-le-Willows.

He left school when ten years old, and went as a clerk to a lawyer at Tarporley, Cheshire.

When Dr. Jas. Young, F.R.S., then manager of Muspratt's Works, took the management of Tennants' Works at Ardwick Bridge, Manchester, he induced Peter Hart's father to come and assist him. Peter Hart soon left Tarporley to join his father in Manchester, but returned to Warrington to enter the office of Mr. W. Beaumont, a well-known lawyer and antiquarian of that town, and first Mayor of Warrington. He stayed here three years, acquiring a general education under Mr. Beaumont's superintendence. In January 1849 he returned to Manchester and entered the service of Messrs. Tennant, commencing in the office. A few months later an event occurred which placed him in the position he desired—that of assistant to James Young. He now attended evening classes in chemistry at the Old Mechanics' Institution in Cooper Street, under Dr. Allen, and thus wisely supplemented the experience he was gaining under Young. It was whilst Young was working out his process for distilling paraffin oils from crude petroleum and from cannel shales, that Peter Hart thus acted as his assistant. About the year 1851 Young manufactured, at Ardwick Bridge, some tons of solid caustic soda from the ordinary caustic liquors, for use in his oil-refining process. Probably this is the earliest record of the manufacture of solid caustic in England. It is a date previous to that of Gossage's patent, *viz.*, May 18, 1853. Young finally left Ardwick Bridge in order to carry out his process of paraffin oil production on a large scale, and the elder Hart then assumed the managership, with his son as chemist of the works.

About this time Peter Hart improved the then existing method employed by Young for the estimation of tin in *Cassiterite*. Knowing the extreme activity of potassium cyanide as a reducing agent, he made use of this power in carrying out the improved method. He added a known weight of the *Cassiterite* to fused potassium cyanide, removed the cyanate and excess of cyanide, dissolved the reduced tin in hydrochloric acid, and titrated in the usual manner. Among numerous analytical methods published in the *Chemical Gazette* and devised by Hart, one is of special interest. It is the one he worked out for the "Estimation of Sesquioxide of Chromium in Chrome Ore"—a method now well known everywhere. It is based on the solubility of sesquioxide of chromium in fused borax, with subsequent oxidation with potassium nitrate and alkaline carbonate. This method is published by Fresenius in his classical work on *Quantitative Analysis* (the 4th edition, pages 387—388), with a note of reference as to original source, *viz.* the *Chemical Gazette* of 1855.

At the request of Dr. Sheridan Muspratt in 1860, when he published his noted "Dictionary of Applied Chemistry," Peter Hart wrote the article on the "Manufacture of Sulphuric Acid." In 1866 his father met with an accident in the laboratory, which ended in his death, and the son then assumed full managerial control of the works.

Hart read, in the years following, quite a series of papers before the Literary and Philosophical Society of Manchester.

In 1885 Messrs. Tennants and Co. decided to remove their works from Ardwick Bridge—almost the centre of Manchester—to Clayton, and the duty of designing new plant and arranging the new factory devolved upon Hart, and was carried out under his superintendence.

Gifted with indomitable perseverance, shrewd judgment, and a quaint humour, Peter Hart was a typical *Manchester man* in the best sense of the word. He died on Sunday evening, May 30th, after a short illness, in his sixty-third year.—W. S.

### DR. C. REMIGIUS FRESENIUS.

GEH. HOFRATH UND PROFESSOR, DIRECTOR DES CHEMISCHEN LABORATORIUMS ZU WIESBADEN.

WE note with regret the decease, on the 11th inst., of that great veteran of analytical chemistry, C. Remigius Fresenius, whose laboratory in Wiesbaden, whose textbooks on qualitative and quantitative analysis, and whose organ, the *Zeitschrift für Analytische Chemie*, have long ago attained world-wide fame.

Fresenius was born on December 28, 1818, at Frankfurt-on-the-Maine. His chemical training he obtained in Giessen, in the laboratory of Liebig, and at the close of his student career he remained with his great teacher as assistant, along with Witt and Hofmann, at that time also Liebig's assistants.

Fresenius now prepared himself for, and eventually assumed, the rank of a "Privatdozent" of the University of Giessen. This position he, however, shortly relinquished, in order to found a laboratory of his own in Wiesbaden. To the development and perfection of this institution Fresenius has dedicated a life-long active interest, and though in the main the courses of chemical study there have been on the applications of the science to industry, yet many young chemists have not considered their curricula complete without including Fresenius' analytical course at Wiesbaden.

In the earlier years of his life Fresenius had become engaged in industrial pursuits. He was connected with the *Verein für Chemische Industrie* in Frankfurt, and the *Verein Chemischer Fabriken* in Mannheim. In both these companies Fresenius was a member for many years of the respective directorates, and once or twice he held the position of chairman. In the words of his biographer, Dr. Otto N. Witt, in *Die Chemische Industrie*, June 15, 1897, reference may be made, in closing, to the esteem with which he is regarded both in the Vaterland and beyond it: "Sein Andenken wird bei Allen, die ihn gekannt haben, fortundern als das eines bedeutenden Gelehrten und eines wahrhaft guten Menschen."—W. S.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Asbestos for Chemical Purposes, The Manufacture of Acid-Proof.* F. Schrader. Chem. Zeit. 1897, 21, 285.

ALTHOUGH the name asbestos is generally understood to apply to a fibrous substance largely composed of magnesium silicate, yet the name has been commercially applied to so many articles possessing varied chemical and physical properties, that it is not surprising that the above-mentioned terms asbestos contain no magnesia or only traces.

Chemical manufacturers have long desired and felt the need of a substance suitable for packing or millboard, and capable of withstanding alike high temperature and resisting strong acids and alkalis. The author has therefore investigated about 50 different forms of asbestos, which were on the market, with this object, and has arrived at the following conclusions:—1st. That to withstand alike high temperature and strong acids, or caustic alkali, asbestos should be of the character of hornblende, in which the base should be to silicic acid as 1:1, and of the formula  $RSiO_3$ , R representing magnesia.

Asbestos (serpentine asbestos) in which the proportion is 3:2, is capable of resisting high temperature, but not acids—even tartaric and acetic acids removing the bases and leaving almost pure silicic acid without apparently destroying the fibrous condition.

Boiling for four hours with dilute hydrochloric acid (5 per cent.) also effects the same end.

This latter form of asbestos (serpentine asbestos), on account of its fine and soft fibre, is particularly suitable for weaving and many technical applications other than chemical; whilst the former, owing to its acid-resisting character, is capable of employment in chemical works.

—O. H.

### PATENT.

*Material suitable for Belting, Carding, Cloths, Soles of Boots, and the like Uses; Impts. in the Manufacture of.* F. W. Oliver, London. Eng. Pat. 10,104, May 12, 1896.

See under V., page 532.

## II.—FUEL, GAS, AND LIGHT.

*Mond Gas-Producer Plant and its Applications.* H. A. Humphrey. Proc. Inst. Civil Eng. 1897, 129, 1—29.

SEE this Journal, 1889, 505—510; also (for Patents), 1884, 236; 1886, 235; and 1894, 938.

The experiments described in this paper were made on a producer plant similar in its general arrangement to that previously described in this Journal, 1889, 505 *et seq.* Improvements had, however, been introduced in making the producer circular, and by means of a system of concentric tubes, economising to a greater extent the heat present in the different portions of the apparatus.

The present tests were made in 1895, under the ordinary working conditions as regards the producers, whilst the gas from 62, 82, and 94 tons of fuel per day respectively, was driven through one set of towers. The best results were obtained from the first test, that is, when the absorbing plant had the least work to do; but the figures of the second trial have been selected as more nearly corresponding with usual conditions. The fuel consisted of Nottingham slacks fed into the producers in charges of 8 to 10 cwt. at a time; the burnt ashes were removed from three of the six lute-holes alternately, the lutes untouched during one shift being drawn at the next.

The density of the sulphate liquor was kept at 35° Tw. (31 per cent. of sulphate of ammonia by weight), so that for every ton of solid sulphate subsequently made, it was necessary to evaporate  $2\frac{1}{2}$  tons of water. By actual measurement of all the condensed steam from the sulphate plant, it was found that 5·6 tons of steam were condensed in performing this work, together with the necessary pumping.

The results of the trial showed that for every ton of fuel fed into the producers, about  $2\frac{1}{2}$  tons of steam and 3 tons of air were blown through the grate, the mixture being at

a temperature of 250° C. Of this steam, 1 ton is furnished by the system of regeneration and  $1\frac{1}{2}$  tons is added as exhaust steam. More than  $\frac{1}{2}$  ton of steam is decomposed in passing through the hot fuel, and nearly  $4\frac{1}{2}$  tons of gas are formed from 1 ton of coal, equal to about 160,000 cb. ft. at ordinary atmospheric temperature. This gas has a calorific value of 81 per cent., calculated on the calorific value of the original 1 ton of fuel, and in a Babcock-Wilcox boiler, gives an evaporation of somewhat more than 7 tons of water. When used in a gas engine, it is sufficient to give 2,166 I.H.P. hours, being at the rate of 1·03 lb. of slack per I.H.P. hour, the thermal efficiency of the engine being 23·8 per cent. For each ton of slack gasified, the plant requires a supply of exhaust and direct steam equal to 0·242 ton of slack; this is allowed for in all calculations. The efficiency of the tubular generator is 81·9 per cent., against one of 72·07 when using circulating water. Diagrams are given showing the changes in pressure and temperature throughout the absorbing plant, the highest pressure being 310 mm. of water.

By burning cold Mond gas with the proper amount of cold air, the temperature of combustion, as actually observed, is 1,150° C.; whilst the theoretical temperature, calculated from the calorific value and specific heats, is 1,606° C. In this calculation the gas is taken as saturated at 15° C., and the air as half-saturated with aqueous vapour at the same temperature. When regeneration is employed, the difference between a poor and a rich gas begins to disappear, and with Mond gas, used in its wet condition, it is easy to reach temperatures beyond the range of any form of pyrometer available. With a Callander pyrometer, a temperature of 1,525° C. has been observed in a flue through which burnt gases from a Mond gas-fired steel furnace were passing.

In treating of the applications of producer gas, the author states that where gas has replaced slack-firing, 1·1 to 1·2 ton of coal in the producers is equivalent to 1 ton of good slack carefully burnt by the old method, and that very frequently the working results approach much more nearly to one of equality in weights of slack. Among the advantages claimed for the use of gas are, saving of labour and prolonged life of plant, certain cast-iron pans at the works of Messrs. Brunner, Mond, and Co. lasting with gas-firing four times as long as with coal-firing.

To show what might be accomplished in the supply of cheap power, the author takes as a hypothetical example a factory requiring a continuous power of 10,000 I.H.P. With a Mond producer and recovery plant to supply the necessary gas, and assuming the whole power to be utilised to drive dynamos yielding 7,000 E.H.P. at the terminals, allowing 20,000*l.* as the cost of the producing plant, and 120,000*l.* for buildings, gas engines, dynamos, &c. (exclusive of land)—the working expenses, day and night, for a year are estimated at 33,100*l.*, which includes interest on capital at 8 per cent. On this basis the total cost of one kilowatt-hour is 0·184*d.*, or of one E.H.P.-hour 0·137*d.* Should the mechanical power be used without transformation, this cost would be reduced to 0·0865*d.* per I.H.P.-hour.

The paper closes with three appendices, which contain the data from which the figures given in the text are abstracted, a few of which follow:—

### APPENDIX I.—TABLE V.

*Cost of working per Ton of Sulphate of Ammonia made.*

	£	s.	d.
Total cost of all fuel (28·56 tons at 6 <i>s.</i> 2 <i>d.</i> ) .....	8	16	1
Wages at producers (23 tons at 6·4 <i>d.</i> ) .....	0	12	3
Manufacturing wages, administration .....	0	1	9
" " labour .....	0	19	8
Repair wages and materials, including renewals .....	0	18	3
Gas for lighting purposes .....	0	3	11
Lubricants .....	0	1	8
Sulphuric acid, 0·95 ton at 14 <i>s.</i> 7 <i>d.</i> Tw. ....	1	4	4
Total for above .....	12	17	11
Selling price of sulphate, naked at works .....	7	4	6
Final works cost of 23 tons of fuel gasified .....	5	13	5
Or the cost of 1,000 cb. ft. of gas (at 15° C.) is...	0	0	0·351
The gas for 1 I.H.P.-hour will cost .....	0	0	0·02685

burners respectively. The nitrogen liberated in the distillation of the coal cannot be excluded from the gas, but a quantity not exceeding 2 per cent. is left therein if atmospheric nitrogen be excluded by careful working. Aqueous vapour is injurious to the illuminating power, but in practice it cannot be excluded from the gas.

The cost of enrichment by the admixture of two gases is calculated by the following rule:—Let  $a$ ,  $b$ , and  $c$  denote illuminating power of enriching, unenriched, and enriched gas; and  $p$ ,  $q$ , and  $r$  the cost per 1,000 cb. ft. of enriching, unenriched, and enriched gas: then  $\frac{r - q}{c - b} = \frac{p - q}{a - b}$  = cost of enrichment per 1,000 cb. ft. per candle-power.

A ton of coal yielding 11,900 cb. ft. of 15-candle gas is assumed to cost 8s. 9d., and a ton of canal yielding 11,466 cb. ft. of 28.54-candle gas, 15s., delivered at the works. The assumed cost per gallon of carburine, having a specific gravity of 0.680, and distilling completely between 90 and 230 F., is 7½d.; that of petroleum spirit, sp. gr. 0.700, distilling between 95 and 310 F., is 5½d.; and that of 90 per cent. benzol, sp. gr. 0.881, is 1s. The Maxim-Clark carburettor is that usually employed for enriching gas by the vapour of these light hydrocarbons. A sample of spirit prepared from the hydrocarbon residue of the

compressed oil-gas works appeared to be superior to carburine and benzol as a carburetting agent, but the increase in illuminating power was not exactly determined. Oil-gas for enriching purposes is prepared by the Young and Bell fractional gasification method or by the Caldwell and Tatham oxy-oil method. The first method gives 22,000 cb. ft. of gas per ton of Scotch shale oil, sp. gr. 0.875; similar but rather heavier oil (sp. gr. 0.878) yields by the second process 23,205 cb. ft. of gas, to which 4,080 cb. ft. of oxygen at 4s. 6d. per 1,000 cb. ft. are added in the receiving main. The oil in both cases is assumed to cost 3l. 7s. 6d. per ton delivered, and the illuminating power of the gas is estimated on the basis of its enrichment value (see table). The Lowe type of carburetted water-gas plant makes 1,000 cb. ft. of 24-candle gas from 3.45 gals. of Russian kerosene and 45 lb. of gas-coke, and the same quantity of 30-candle gas from 5 gals. of kerosene and 40 lb. of coke. Gas-coke is taken at 6s. 8d. per ton, and kerosene at 2½d. per gallon, delivered. The following table is compiled on the basis of the foregoing prices for raw materials, and of current rates of wages, and covers all capital and maintenance charges, whilst allowance is made for the receipts from by-products wherever such are obtained. The holder price of 15-candle coal-gas is assumed to be 9d. per 1,000 cb. ft.

TABLE SHOWING COST OF ENRICHMENT PER CANDLE.

Enriching Agent.	Cost per 1,000 cb. ft.	Illuminating Power by Direct Testing.		Illuminating Power by Enrichment Value.		Cost of Enrichment per 1,000 cb. ft. per Candle.	
		Candles.	Cost per Candle.	Candles.	Cost per Candle.	Direct Testing.	Enrichment Value.
Canal gas.....	d.		d.		d.	d.	d.
Carburine vapour.....	16.75	28.54	0.586	..	..	0.552	..
0.700 spirit.....	..	..	..	..	..	..	1.218
Benzol.....	..	..	..	..	..	..	1.072
Young's oil-gas.....	40.00	..	..	..	..	..	0.600
Oxy-oil-gas.....	48.00	..	..	..	..	..	0.413
Carburetted water-gas.....	13.92	24.0	0.580	126	0.381	..	0.351
"	17.00	35.0	0.503	"	..	0.546	..
"	"	"	"	"	..	0.430	..

\* It has been observed that the enriching value of carburetted water-gas is from 6 to 20 per cent. higher than the direct illuminating power. Similar behaviour is probably true of canal gas.

—J. A. B.

#### Acetylene, A Bunsen Burner for. A. E. Munby. Proc. Chem. Soc. 1897, [179], 103.

WE employ a Bunsen burner of special dimensions, the tube being 5 mm. in internal diameter. A slightly wider tube may be used, provided the mouth be curved inwards, so that the actual exit does not exceed the diameter mentioned; if larger, the flame tends to strike down. The gas jet is very small, being only capable of delivering about 1 cb. ft. of acetylene per hour under 6 ins. water pressure, such a rate of consumption giving an ordinary working flame. The air holes and collar are arranged as in an ordinary Bunsen, the exact size of the former not being of much importance, provided they be large enough to admit the air required. The burner is protected with a cap, when not in use, as its efficiency depends upon the jet maintaining its dimensions. A generator capable of giving gas under 7 ins. water pressure with the full number of burners in use, is required. Under this pressure a large and perfectly blue flame is obtained, which may be turned down to what may be termed a quarter Bunsen flame, equivalent to burning the gas under 3 to 4 ins. water pressure. This is the smallest pressure with which the burner will give a non-luminous flame. When turned lower, the zone of partial combustion appears, since the draught is then insufficient.

The heating effect of the flame is of course very great, enabling one to dispense with the blow-pipe for some operations, such as small fusions. From a few experiments on heating equal quantities of water under like conditions with coal-gas and acetylene, it would seem that in practice, for equal volumes burnt, the latter has nearly twice the heating power of the former.

#### Calcium Carbide, New Economical Preparation of. H. Marx. Monit. Scient. 1897, 11, [4], 276—281.

THIS paper consists of a critical discussion of Heibling's work on the electrolytic preparation of iron alloys (this Journal, 1896, 726). In thermo-electric metallurgy, it is necessary that the whole substance under treatment should become fluid, and also that the slag produced should be a conductor. When lime is employed as a flux, a slag of fusible calcium carbide is formed, which, besides being a valuable product, is an excellent conductor. The results of some experiments carried out at Puteaux, show in a marked manner the value of lime as a flux, the horse-power diminishing according to the amount of lime used, whilst the yield of acetylene per kilo. of calcium carbide, increases.

—J. L. B.

#### Acetylene, A New Method of Storing. G. Claude and A. Hess. Comptes Rend. 1897, 124, 626—628.

ACETONE at 15° and under ordinary pressure, dissolves 25 volumes of acetylene, and under 12 atmospheres, 300 volumes. Thus the solubility increases nearly in proportion to the pressure. The solubility in acetone is diminished by half on passing from 15° to 50°, and therefore the pressure in a reservoir doubles for a rise of about 30°. With liquid acetylene a pressure of 24 atmospheres increases to 70 for a rise of 18°. Dissolved acetylene may therefore be stored safely in weaker and lighter vessels than liquid acetylene, and since its coefficient of dilatation is very much lower, the vessels may be more nearly filled. A platinum wire, maintained at bright redness by electric current, was held for an indefinite period with impunity in a solution under 3 atmospheres pressure of acetylene in acetone.—J. A. B.

*Acetylene Gas for the Generation of Power, The Applicability of.* H. Schrey. *Ann. für Gewerbe und Bauw.* 1896, Nov. 1, 164; *Proc. Inst. Civil Eng.* 1897, 127, [1], 51—52.

This is the record of some experiments conducted by Ravel in America. It was found that 1.35 parts of acetylene mixed with 1 part of air was explosive, and the explosive force of the mixture rose rapidly as the dilution with air increased, the maximum being attained when 12 volumes of air were mixed with 1 volume of acetylene. Beyond this limit, the explosive force decreases, until at 20 of air to 1 of acetylene, it is entirely extinct. The special characteristics of acetylene are, great rapidity of the transmission of flame, low ignition temperature (about 180 °C.), high combustion temperature, and an extraordinary energy evolved in the explosion. 6.35 cu. ft. of acetylene gas sufficed to generate 1 H.P. per hour. In a small 2-H.P. motor, acetylene gas gave 2.1 times the work of the same volume of illuminating gas. It was found that the cooling of the cylinder by lubrication has a much more important effect upon the working than is the case with coal-gas.

—A. S.

*Incandescent Lighting, A Report on the Use of Spirit for.* Dr. Haydnck. *Zeits. für Spiritusind.* 1897, Supplement II., 22—23.

The illuminating power of incandescent spirit-lamps depends primarily on the mantle and secondarily on the structure of the lamp. The mantle must correspond in shape with the flame. The lamp must be easily managed, readily lighted and extinguished, burn with a steady flame free from smoke and smell, and must not be dangerous. Of several lamps from different firms, the "Phœbus" complied, it is said, with these conditions, and gave the best result. For an hourly consumption of 85 c.c. of 86 per cent. (volume) spirit, it gave an illuminating power of 31 candles. At the current price of spirit it would yield a light of 10 Hefner units strength, at a cost of 0.65 pfennig (in Germany), whereas the same light costs 0.84 pfennig per hour by an ordinary petroleum lamp. Several lamps are described in detail.—J. J. B.

*Ethylene, Action of Nickel on.* P. Sabatier and J. B. Senderens. *Comptes Rend.* 1897, 124, 616—618.

A LAYER of nickel reduced by hydrogen, if heated to 300° and upwards, completely decomposes pure dry ethylene passed over it. The products are only carbon, hydrogen, and methane, in varying proportions. The amount of hydrogen increases with the temperature. Freshly reduced iron, copper, and cobalt, and spongy platinum and palladium, were inactive, and nickel filings less active than the reduced metal. The nickel and ethylene appear to form an unstable compound, which decomposes into carbon, methane, and nickel; and hydrogen is formed by a secondary reaction. The explanation offered by Moissan and Moureu (*Comptes Rend.* 122, 1240; this Journal, 1896, 530) of the decomposition of acetylene by reduced metals in the cold—viz., that it was due to the heat of absorption of the gas by the porous metal provoking decomposition of the endothermic gas—cannot apply in the present case.

## PATENTS.

*Vapour or Gas from Liquid Hydrocarbons, An Improved Apparatus for Producing.* A. I. van Vriesland, Amsterdam. Eng. Pat. 5991, March 6, 1897.

From the bottom of an oil reservoir a pipe rises a short distance, serving as an air-supply shaft. From the reservoir cover rises an exit pipe having a narrowed nozzle. A tubular sheath, "formed of the most absorbent material possible," is drawn over the air shaft, and projects concentrically above it to a certain extent, the projecting part being supported by stiffening wires. The reservoir is filled with the hydrocarbon, or with a substance saturated therewith, so that the sheath draws up the hydrocarbon and evaporates it within the pipe that carries the nozzle. Air is drawn up the supply shaft, becomes saturated with the hydrocarbon vapour, and passes out at the nozzle as a combustible mixture.—H. B.

*Combustible Gases, Improved Process and Plant for Generating.* B. H. Thwaite, Westminster. Eng. Pat. 8384, April 21, 1896.

IMPROVEMENTS in processes and plant described in previous patents by the same inventor, viz., Eng. Pat. 13,385, 1894 (this Journal, 1895, 794); and Eng. Pat. 18,445, 1894 (this Journal, 1895, 856). When producing gas in a single-vessel generator from hydrocarbon fuel, the two tubes for gas and air, each having openings into the generator at the top and the bottom, have each a valve so connected together by gearing that both are reversed by turning one hand wheel. Thus, the fuel may be preliminarily and occasionally intermittently blown up to a state of incandescence before the air is introduced. When using a duplex gas generator working in a continuous cycle, the upper part thereof is encased in a water jacket for the purpose of generating steam.—H. S.

*Carburetted Water-Gas, Impts. in Apparatus for the Manufacture of.* The Economical Gas Apparatus Construction Co., Ltd., London, and L. L. Merrifield, Franklin, U.S.A. Eng. Pat. 11,530, May 27, 1896.

ONE superheater and fixing chamber is connected with two generators in such a way that the gases and vapours from the top of either generator can be led to the top of the other generator, and, after passing down through the fuel therein, are conducted to the superheater, where they are carburetted in the usual way. The order of the action of the generators can be reversed by means of suitable valves. Steam may also be passed downwards through both generators simultaneously, or upwards, in each case passing directly to the carburetting chamber.—H. B.

*Water-Gas, An Improved Manufacture of.* J. E. Goldschmid, Frankfurt a/Main, and C. Dellwik, Stockholm. Eng. Pat. 11,632, May 28, 1896.

By means of a pipe passing beneath the grate, and a series of twyers at various heights in the generator, air is introduced into the coke or the like at different points. The coke is rapidly raised to incandescence, producing chiefly carbon dioxide. The steam is then passed alternately from above and from below, preferably two admissions from the bottom to one from the top. A locking arrangement is applied to the valves in such a way that the outlet valve for the combustion gases cannot be closed as long as the water-gas valve remains closed, and vice versa.—H. B.

*Oil or Vapour Burners or Atomisers for Heating Purposes, Impts. in.* H. H. Lake, London. From T. R. Browne, Altoona, U.S.A. Eng. Pat. 12,338, June 5, 1896.

THE burner is adapted for use outside a furnace, to which it is connected by an adjustable arm. It consists of an oil-spraying nozzle, having a central air channel and an annular outer air channel, and oil passages situated between these channels. Owing to the sides of the annular air passage converging towards the mouth-piece of the nozzle, the latter throws a jet of air and oil, which first converges towards and then diverges from a point in front of the nozzle. Situated about 4 or 5 ins. in front of the nozzle is

the receiving nozzle of the furnace, having its inner walls proportioned and flared to conform with the size and shape of the mixed oil and air jet, and having its outer part abruptly flared outward. Instead of compressed air, steam may be used in atomising the oil.—H. B.

*Gas, The Manufacture or Preparation of Improved Odourising Substances [Isocyanides] for Artificially Imparting Odour to.* H. Strache, Vienna. Eng. Pat. 14,941, July 6, 1896.

To impart a strongly characteristic odour to odourless poisonous or explosive gases, they are led over material (shavings, pumice, &c.) saturated with one or more "carhylamines" (isocyanides), or over the isocyanides alone. In producing the latter, an amine (say 30 grms. of aniline) is dissolved in alcohol (600 grms.), then decomposed with alkali (100 grms. of sodium hydrate to 70 grms. of water), and chloroform (45 grms.) is cautiously added, with stirring. The mixture is frequently shaken during one day, and then allowed to settle, when the dilute product, containing about 3 per cent. of isocyanide, may be employed directly for odourising gases. To obtain a concentrated product, pour the calculated quantity of aniline over fine granular soda lime, heat to about 100° C., and add cautiously the calculated amount of chloroform, drop by drop, with continual stirring. After cooling, a part of the carbamine can be poured off from the solid chlorides of sodium and calcium; what remains can be obtained in strong solution by leaching with the smallest practicable quantity of alcohol.—H. B.

*Hydrogen Gas, The Utilisation of, for the Obtainment of Light, Heat, and Power.* L. V. Pratis and P. Marengo, Turin. Eng. Pat. 16,277A, July 22, 1896.

THE burner for the hydrogen is of much the usual type, and the mantle is suspended over it in the usual way. When using hydrogen for driving gas engines, the inlet port for the air should have a sectional area of about 18 times that for the hydrogen. The three claims are: for the obtaining of light by burning hydrogen in contact with hoods of platinum gauze or of earths, &c.; the utilisation of hydrogen for obtaining heat or power; and the utilisation of hydrogen by compressing it and applying it to the illumination of trains, &c.—H. B.

*Illumination, partly by Flame and Partly by Incandescence; Impts. in the Method of and Apparatus for Effecting.* J. B. de Léry, New York. Eng. Pat. 7920, March 27, 1897.

THE claim is for the "combination, with a gas burner adapted to throw a series of flames into the form of a crown, of a circular or disc-like web or netting of incandescing material arranged above the crown of flame in a horizontal plane." "This is placed at such a level as to be struck by the tips of the flames." The combined illumination by flame and by incandescence is also claimed.—H. B.

*[Mantles.] Incandescence Bodies for Illuminating Purposes, Impts. in the Manufacture of.* W. Nicholls, London. Eng. Pat. 9241, May 1, 1896.

IN manufacturing mantles in the usual way, the fluid is to be prepared from the following:—Zirconium nitrate, 250 parts; calcium chlorate, 100 parts; ammonium nitrate, 160 parts; uranium nitrate, 5 parts.—H. B.

*Mantles or Incandescing Bodies for Incandescent Gas Lamps, Impts. in the Manufacture of.* J. F. Duke, West Dulwich. Eng. Pat. 13,659, June 20, 1896.

To render the mantles more durable, to increase their lighting power, and to obviate the greenish tinge usually acquired by the light after some time, the mantles, after receiving their usual coating of collodion, are dipped in a solution of barium salt (preferably cold saturated BaCl<sub>2</sub> solution). They are then dried and highly heated over a Bunsen burner until the barium salt is converted into oxide, a slight fusion taking place, which causes the barium oxide to be permanently retained.—H. B.

*[Mantles.] Incandescence Bodies for Incandescent Gas Lighting, Impts. relating to.* C. Killing, Düsseldorf. Eng. Pat. 14,365, June 29, 1896.

THE provisional specification describes the use of a large number of substances added in minute quantity to pure thoria mantles, but the complete specification describes only the manufacture of mantles in the usual way from fluid composed of 4 grms. of thorium nitrate, 10 c.c. of water, and 8 drops of iridium chloride solution containing 0.0023 grms. Ir per c.c. The claim is for "An incandescence mantle containing, in addition to thoria, a small quantity of iridium, substantially as described."—H. B.

*Peat for Fuel, and to Apparatus therefor; Impts. relating to the Preparation of.* C. D. Jenkins, Boston, U.S.A. Eng. Pat. 8402, April 21, 1896.

THE peat is first passed through a horizontal drying chamber provided with a screw conveyor, with a heating jacket, and with pipes connected with an exhaust for drawing off air and other gases from the peat. Dry or superheated steam or heated compressed air is forced through this chamber. After leaving the dryer, the peat is passed into a special press or pug mill, two forms of which are shown, in which it is forced by a taper screw through a gradually decreasing passage while subjected to a partial vacuum. It is finally cut up into pieces of a convenient size and shape.—R. S.

*Artificial Fuels [Briquettes], Improved.* R. Bradshaw, Ash Grove, Liverpool. Eng. Pat. 9599, May 6, 1896.

BLOCKS or briquettes are formed either solid (that is, of one mixture throughout), or compound (that is, having a core or a number of cores or layers of a more readily inflammable material than the bulk of the block). The solid briquettes are formed of a base of bituminous or anthracite coal-dust, or slack, or coke-dust, or a combination of the same, with ingredients for binding, and are shaped with flat surfaces or with corrugations. The main bulk of the compound briquettes is formed of coal or coke dust or anthracite, farina, alga, and potato starch; while the cores or more inflammable layers are formed of petroleum, astatki, resin, gas-tar, saltpetre, or their equivalents.—R. S.

*Artificial Fuel, An Improved, and Process for Producing the same.* J. Kohndorfer, Landshut, Bavaria. Eng. Pat. 5669, March 3, 1897.

PETROLEUM is converted into a fuel of consistent form, by heating it with soda lye (about 10 per cent.) and a fatty substance (about 10 per cent.), or resin; either coal-dust, sawdust, &c. may also be added.—R. S.

*Illuminating Gas, Impts. in Treating Peat, Coal, and other Carbonaceous Substances for the Obtainment of.* J. Meikle, Maryhill, N.B. Eng. Pat. 11,951, June 2, 1896.

A SPRAY of hydrocarbon or carbonaceous oil is injected by means of superheated steam into gas made from peat, coal, and other carbonaceous substances, either at the time when being formed or immediately afterwards.—R. S.

*Coke Ovens, Impts. in Horizontal.* O. Imray, Southampton Buildings, London. From F. Bruuck, Dortmund, Prussia. Eng. Pat. 12,535, June 8, 1896.

THE air supply for such ovens is highly heated before passing into the oven, by its passage through a grating-like partition wall, on each side of which is a flue through which the hot gases from the oven pass.—R. S.

*Acetylene Gas, Method and Means or Apparatus for Facilitating the Combustion of.* C. Coppeaux, Brussels. Eng. Pat. 9630, May 6, 1896.

THE object of this invention is to overcome difficulties in the use of acetylene for lighting purposes arising from the relatively large volume of air required for its perfect combustion. Air is supplied under pressure to the burners from a conduit.—J. A. B.

**Gas [Acetylene] Generators, Impt. in.** W. Jordan, Chancery Lane. From The Morley Acetylene Gas Co., Wheeling, and Wall St., New York, U.S.A. Eng. Pat. 10,126, May 12, 1896.

IN one form the generator consists of an enclosed vertical, cylindrical vessel, placed within another cylindrical vessel, open at the top and containing water, a central tube open at both ends passing upwards through the bottom of the generator, so that water can pass from the outer reservoir to a number of branch outlets arranged at different levels in the central tube, and flow upon the carbide. Another tube passes through the said pipe and serves as a delivery pipe, being open at the top and leading to a gas-receiver, either a collapsible bag or a small gasometer. In either case, as the gas-receiver rises, the pressure on the gas is increased by means of weights, tending to drive the water away from the carbide. Suitable valves are provided for regulating the passage of the gas.—R. S.

**Generating Gas [Acetylene, &c.], Improved Apparatus for Automatically.** G. Webb, jun., Shepherd's Bush, and J. W. Kelly, Finsbury Pavement. Eng. Pat. 10,725, May 18, 1896.

RELATES to automatically generating such gases as acetylene, by the action of water upon a solid compound.—R. S.

**Acetylene Gas, Improved Method of and Apparatus for Generating.** M. C. A. Fourchotte, Paris. Eng. Pat. 12,017, June 2, 1896.

ATTACHED to the bell of a gasholder is a pipe or chamber, the lower end of which is sealed in the water in the tank, and slides over the mouth of a smaller tube which rises through the bottom of the tank nearly to the level of the water. This tube communicates externally with a generator containing calcium carbide. There is confined within the pipe attached to the bell a certain volume of air or gas, which becomes compressed by the sinking of the bell and forces water from the tank through the tube to the generator. The gas generated in the latter passes through a hydraulic seal into the gasholder, the bell of which it lifts, and thus relieves the pressure of the air in the chamber and cuts off the flow of water to the generator. When the bell again falls, a further supply of water is forced into the generator.—J. A. B.

**Acetylene Gas, An Improved Apparatus for Generating.** F. H. Haviland, A. Holloway, J. B. Collier, and W. H. Murch, Bournemouth. Eng. Pat. 15,122, July 8, 1896.

A VESSEL is divided horizontally into two compartments, of which the upper serves as a cistern and the lower as a gasholder. There is a space between the compartments. The water preferably flows from the cistern through a syphon-shaped pipe to a "pressure cylinder," and thence to the base of the gasholder. The pressure cylinder remains filled so long as there is water in the cistern. One or more generators are supplied with water from the gasholder. The water enters the generator at its base, and either passes up a pipe from the mouth of which it drips on to the calcium carbide, or is carried up by a wick, filling the annular space between the wall of the generator and a perforated carbide receptacle within it. The gas passes from the generator, through a cooling coil within the cistern, to a purifier and drying chamber, and thence to the point of consumption or to the gasholder.—J. A. B.

**Acetylene Gas, Rendering it inactive when brought into Contact with Metals with which it forms Explosive Compounds, A Process for.** G. Isaacs, Charlottenburg. Eng. Pat. 15,139, July 8, 1896.

To prevent acetylene, which, it is found, always contains ammonia, forming explosive compounds with copper, silver, mercury, and other metals, any sulphuretted hydrogen present is first eliminated by means of powdered iron ore, after which the gas is treated with substances which will absorb the water and ammonia present.—R. S.

**Acetylene Gas, Impts. in Means or Apparatus for Use in the Production, Storing, and Application of.** T. Holliday, Huddersfield. Eng. Pat. 885, Jan. 12, 1897.

THE apparatus consists of one or more generators placed on a level with or below a displacement gasholder. The generator contains a reticulate cage to retain the lime residue which falls from the calcium carbide in a perforated cage above it. (Eng. Pat. 5813, 1896; this Journal, 1897, 319.)—J. A. B.

**Acetylene Gas, Impts. in or relating to the Production of [from Carbides].** V. Daix, Paris. Eng. Pat. 911, Jan. 13, 1897.

THE carbide is placed in vessels arranged within the generator so that the water overflows from the upper vessel into the one next below it, and only a small portion of fresh carbide is at any time in contact with water. The carbide receptacle is surrounded by a water chamber in which the gas evolved is washed and cooled. The gas enters a bell gasholder, to the bell of which is attached a siphon device which supplies water to the generator from the gasholder tank until the bell has risen above a certain level.—J. A. B.

**Acetylene and certain other Gases, An Improved Generator for.** E. H. Fernand des Essards, Paris. Eng. Pat. 1152, Jan. 15, 1897.

THE generator consists of two superposed hermetically-closed vessels, communicating by a device which permits water to flow from the upper to the lower vessel under constant pressure.—J. A. B.

**Acetylene Gas Lamps and Generators.** W. H. Dennis, Minneapolis, U.S.A. Eng. Pat. 2976, Feb. 4, 1897.

THE object is to provide a generator which may be embodied in a table or wall lamp. Two tanks are attached to a suitable upright, which may serve to convey the gas to the burner or burners. One tank contains water, which may pass through a duct near its base to the foot of the other tank, wherein is a carbide holder. The water may pass up the annular space or "water-leg" between the walls of the tank and carbide holder and overflow into a distributing cone on the top of the latter. The gas generated, passes upwards through a basket containing purifying material, and then through a pipe to a condensing coil in the water-tank. In the event of too rapid production, the pressure of the gas depresses the water in the water-leg, and prevents it flowing into the carbide holder.—J. A. B.

**Acetylene and other Gases, An Improved Combined Automatic Generator, Condenser, and Holder for.** H. R. Bean, Plaistow, and H. Ringwood, Poplar. Eng. Pat. 5756, March 4, 1897.

WITHIN a double-walled tank moves a bell forming a gasholder, to the crown of which is attached a chamber containing a basket filled with carbide; the lower portion of the chamber is contracted and surrounded by an air vessel which regulates the pressure of gas. The top of the tank bulges to form an annular space for the reception of water displaced by the pressure of the gas generated.—J. A. B.

**Acetylene Gas, Impts. in the Manufacture of [Use of Steam], and in Apparatus therefor.** G. Percire, Paris, E. Sorel, Paris, and B. Cruvellier, Marseilles. Eng. Pat. 6997, Mar. 17, 1897. (Under International Convention.)

STEAM is used in place of liquid water for the decomposition of calcium carbide, and the action may be instantaneously stopped by closing a steam-cock.—J. A. B.

**Acetylene Gas, Impts. in Apparatus for Generating.** E. G. Brewer, London and Leeds. From The Gesellschaft für Acetylen-Gaslicht Basel, Bale, Switzerland. Eng. Pat. 7744, March 25, 1897.

A GENERATOR with removable bottom is immersed in a water-tank. A basket containing calcium carbide is supported on the bottom of the generator. A conical cap projects over the top of the basket, and prevents water reaching the carbide from the top. To the top of the

generator is attached a cross tube, one arm of which leads to a gasholder, and another to a safety-valve. The vertical arm is attached to a tube supporting a water vessel and furnished with a five-way cock, by means of which air or gas from the generator may pass to the water vessel while water passes in the opposite direction, or by means of which gas may pass out through a side arm. The top of the water vessel is provided with a tube having a cock with double passage ways, one of which communicates with a funnel and the other with the open air. Thus the air can escape from the vessel while it is filled with water through the funnel. By manipulation of the cocks, water passes slowly from the water vessel and reaches the carbide from beneath, while gas replaces the water from the vessel, and allows its flow to continue.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Automatically Generating.* H. H. Lake, London. From F. Ferracini, Savona, Italy. Eng. Pat. 7782, March 25, 1897.

This apparatus consists of a gasholder supported on a tripod, and a generator which is clamped to the bottom of the gasholder and connected with the tripod. The generator contains four small movable baskets each with a central tube suitably perforated so that water descending from a funnel on the top basket first moistens the carbide in the lowest basket. The space within the gasholder bell is nearly filled by an impermeable drum attached to its crown and serving as a float. The acetylene evolved, causes the float to rise and when its bottom has reached the level of the water in an external basin, the supply of water to the generator is automatically cut off.—J. A. B.

*Electrical Furnaces [Carbides, &c. under Vacuum or Pressure], Impts. in or relating to.* A. J. Boulton, London. From O. Patin, Paris. Eng. Pat. 19,290, Sept. 1, 1896.

ELECTRICAL furnaces are described "adapted for the manufacture of calcium carbide and treating in vacuum [or under pressure] bodies which are liable to become oxidised by the action of air." "The important feature of the invention is the moving of the material as it is being treated by the electrodes." The four claims are for mechanical parts, and their combination and arrangement constituting a complete electrical furnace.—J. C. R.

*Electric Furnaces [Are moved by Magnets], Impts. in and connected with.* F. J. Patten, New York, U.S.A. Eng. Pat. 4138, Feb. 16, 1897.

This invention, illustrated by drawings, "consists in a system of electric furnace construction in which an electric arc, being established between electrodes, is made to move by magnetic (electro-magnets shown) influence from one point to another so as to arrive at and affect material that it would not reach if it remained practically steady at one point or in a fixed position." Claim 1 is:—"The method of operating an electric furnace which consists in passing the material to be operated upon between electrodes, subjecting the arc to the influence of a magnetic field, the lines of force of which are substantially transverse to the direction of the arc, and reversing or alternating either the current in the arc or the magnetic field, whereby the arc is reciprocated transversely to the path of the material."—J. C. R.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Hexane and Trimethylene, Decomposition of, by Heat.* F. Haber and H. Oeschelhauser. J. für Gasbeleuchtung, 1896, 39, 799—805, 813—818, and 830—834.

This work is a continuation of that of Haber and Samoylowicz, to which reference is given in a New Book notice, this Journal, 1896, 302, and Journ. f. Gasbel. 1896, 377 et seq.

The heating was effected in an electric resistance furnace. The resistance consisted, for temperatures below 1,700° C., of a thin tube of platinum-iridium 400 mm. long, 55 mm. wide, and 0.05 mm. thick, with copper tabs soldered to

the ends for connection with the electric current. The middle 240 mm. of the tube was closely wrapped round with asbestos cloth. In this way the temperature of the covered part could be maintained at anything up to about 1,700° C. without the uncovered ends becoming unduly hot. The gas to be heated was passed through another thin-walled tube, just fitting comfortably inside the platinum tube. For moderate temperatures, this inner tube was made of hard glass, for high temperatures of special porcelain (Royal Berlin, No. 7). This porcelain and the metal both began to soften about 1,700° C., and above this temperature a gas-coke tube was substituted for the platinum, the inner tube being dispensed with. In the latter case the tube was, of course, somewhat porous, but by keeping a slight excess of pressure at the inlet, enough of the decomposition products could be driven through for collection at the outlet. All precautions were taken for maintaining temperatures constant and for obtaining true measurements of temperature.

In the analysis, Bunte's burette was generally used. Special tests with pure ethylene showed that (contrary to the statement of Winkler, whose ethylene probably contained ether vapour) ethylene is quantitatively absorbed by bromine, and this method was therefore used for determination of ethylene and its homologues. Hydrogen was estimated by fractional combustion.

*Hexane.*—Decomposition did not commence until the temperature reached about 700° C. At 700°—900° the results were about the same as in the previous experiments except that the acetylene percentage was very slightly higher. At temperatures between 900°—1,000° C. the hexane decomposed yielded on the average—

	Per Cent.
Methane.....	27.7
Olefines (mostly ethylene).....	22.1
Acetylene.....	1.1
Hydrogen.....	2.4
Benzene.....	6.8—10
Carbon.....	3.3
Tar.....	29.2

The production of methane is thus much larger than at lower temperatures, that of the olefines less. Very small quantities only of the higher members of the paraffin and olefine groups were formed. Acetylene, benzene, carbon, and hydrogen appear to be secondary products, the main decomposition of the hexane seeming to be into methane, acetylene, and a highly complex tar. This latter carbonizes on nitration and is probably therefore of condensed olefine structure of low molecular weight, rather than of aromatic structure.

It appears that above about 900° C. the simple decomposition of the hexane is accompanied by destruction of the compounds formed.

*Trimethylethylene.*—Trimethylethylene yielded the following decomposition products:—

	At 750°—790°	At 930°—940°
	Per Cent.	Per Cent.
Methane.....	22.5	27.7
Olefines (mostly ethylene).....	26.8	8.5
Acetylene.....	0.06	0.3
Hydrogen.....	0.3—1.3	1.7
Other gaseous products.....	..	4.5
Carbon.....	Trace	5.1
Benzene.....	..	8.0—13.0
Tar (containing a little benzene).....	45.2	33.7—39.1

At 750°—790° the quantity of methane represented about one methane group from each molecule of trimethylethylene decomposed. The decomposition resembled that of hexane, in the olefines being mainly represented by ethylene, in the small quantities of benzene, acetylene, and hydrogen, and carbon formed, and in the quantity of methane produced. The tar, on the other hand, consisted mainly of olefines of higher molecular weight than the trimethylethylene. The almost entire absence of higher paraffins shows that at low temperatures the addition of hydrogen does not take place readily.

At the higher temperature ( $930^{\circ}$ – $940^{\circ}$ ) trimethylethylene showed similarity to hexane in the higher production of methane (more than 1 molecule to the molecule of initial substance) and of benzene.

At  $1,050^{\circ}$ – $1,060^{\circ}$  C. the gaseous products contain 50 per cent. of hydrogen, 39 per cent. of methane, and 5 per cent. of ethylene, but very heavy tars were formed and so much carbon separated that the tube very soon became stopped. The tar contained naphthalene and benzene. Only a trace (0.005 per cent.) of acetylene was found.

A few experiments were also made with benzene and acetylene.

**Benzene.**—Below  $900^{\circ}$  almost no decomposition occurred. Between  $900^{\circ}$  and  $1,000^{\circ}$  decomposition took place with the formation of higher aromatic condensation products. These products are not the same as those found in the tars from hexane and from trimethylethylene, so that the condensation products from the alliphatic compounds are not secondary products from benzene, but probably condensation products from benzene and acetylene.

**Acetylene.**—When acetylene was passed into the tube at  $620^{\circ}$  C. the temperature immediately rose to, and remained at, about  $638^{\circ}$ – $645^{\circ}$  C. The products were mainly liquid, ethylene forming only 3.2 per cent. and other gaseous products 4.2 per cent. of the initial gas. Of the liquid, about 40 per cent. was benzene and the remainder of higher boiling point. No naphthalene was observed. When acetylene was introduced into the tube at  $770^{\circ}$  the temperature rose to  $790^{\circ}$ , and then much carbon, and a very thick and heavy tar, containing both benzene and naphthalene, was formed. The gaseous products consisted of hydrogen with traces of methane and olefines.

The author could not observe the luminous decomposition of acetylene described by Lewes when his acetylene was quite pure, but noticed it directly a trace of air was present.

—L. T. T.

**Shale Oil, The Production of, in France.** F. Miron. Oesterr. Zeits. f. Berg u. Hüttenw. 1897, 45, 80.

SHALE, in the Permian formation, is quarried and distilled for the production of oil in the districts of Autun (Saône et Loire) and Buxières-la-Grue (Allier). The schist is broken up and carried on endless bands to the retorts, which are constructed of cast-iron. Distillation is carried on for 24 hours. From the 12th to the 20th hour the oil is distilled off, before and after this chiefly steam coming over. The vapours pass through two condensers, ammoniacal liquor being condensed in the first, and oil in the second. The average yield from 1 cb. m. of shale is 40–70 litres of crude oil, 50–65 litres of ammoniacal liquor, and 25–35 cb. m. of uncondensed gases. The crude oil is a dark fluorescent liquid with an alibaceous odour, and a sp. gr. of 0.87–0.91.—R. B. B.

#### PATENT.

**Destructive Distillation of Carbonaceous Substances, Impt. in Vertical Retorts for the.** A. C. T. Tarbrax. Cobbinshaw, near Edinburgh. Eng. Pat. 9944, May 11, 1896.

Over the lower mouth or end of each retort is fixed a bottom piece or table, and "a blade" extends across the middle portion of this, and is so arranged that it can be rocked by means of a rod and other gearing outside, on an axis approximately at the surface level of the bottom piece.

—R. S.

## IV.—COLOURING MATTERS AND DYES.

**Nitroso-Methyldiphenylamine.** Ch. Cloëz. Comptes Rend. 124, (1897), 898–901.

It is a well-known fact that dimethylaniline is readily converted into a nitroso-derivative, but methyldiphenylamine does not yield a dinitroso-derivative, although it contains two phenyl groups. Nitroso-methyldiphenylamine can be obtained in good yield by dissolving 40 grms. of methyldiphenylamine (b. pt.  $284^{\circ}$ – $287^{\circ}$  C.) in 200 grms. of hydrochloric acid (sp. gr. 1.165 at  $17^{\circ}$  C.), cooling to  $-10^{\circ}$  C., and gradually adding 15.2 grms. of sodium nitrite in 70 c.c. of water, maintaining the temperature below  $-5^{\circ}$  C. Crystals of the nitroso-methyldiphenylamine hydrochloride then separate out, and, after solution in water, give, with sodium carbonate, a precipitate of the base. The base is stable, and can be kept indefinitely. It crystallises from methyl alcohol in greenish plates melting at  $44^{\circ}$  C., and can be employed for the production of dyestuffs. Thus by condensing it with dimethyl-*m*-amidophenol in an alcoholic or acetic acid solution it yields a dyestuff very similar to Capri blue, dyeing tannin-mordanted cotton. Moreover, on sulphonation it gives a wool dyestuff. By condensing 2 parts by weight of nitroso-methyldiphenylamine with 3 parts by weight of gallic acid, a product is obtained soluble in sodium carbonate, dyeing wool and silk violet blue, and giving similar shades on mordanted cotton, but somewhat redder than those obtained with gallocyanine. Methyldiphenylamine (185 grms.) can also be sulphonated by heating for 10 hours with ordinary sulphuric acid (100 grms.) to  $160^{\circ}$  C. until a sample is soluble in alkalis. The sodium salt of this methyldiphenylamine sulphonic acid is very soluble in water and alcohol, from which it crystallises in aggregates of microscopical needles. By treating equimolecular proportions of it and of sodium nitrite with the theoretical quantity of hydrochloric acid, a nitroso-derivative is obtained, which can be salted out. This product serves for the preparation of sulphonated dyestuffs. Thus with gallic acid it gives a very bluish-violet which dyes evenly on wool, and approaches certain indulines in shade. With dimethyl-*m*-amidophenol a blue is obtained identical with that formed by sulphonating the direct blue already described.—T. A. L.

**Amido-oreinol and Methyldamido-oreinol, Derivatives of.** F. Henrich. Ber. 30, 1104–1110.

AMIDO-OREINOL and methyldamido-oreinol hydrochlorides are produced by reduction with stannous chloride and hydrochloric acid of the corresponding nitroso-compounds.

**Oxidation of Methyldamido-oreinol.**—An alkaline solution of this compound is readily oxidised in air, or by the action of hydrogen peroxide, to a substance of the formula  $C_{15}H_{14}O_5N_2$ . It appears that the methyldamido-oreinol is first oxidised to the quinone-imide  $C_6H_2 \cdot CH_3 \cdot NH \cdot (OCH_3)O$ , and this product reacts with another molecule of the original substance to form a compound having the constitution—

(or the position of the methyl and methoxy groups may possibly be reversed). Methyl alcohol is also a product of the reaction. The oxidation product forms fine dark-red needles which melt at  $253^{\circ}$  C., and possess feeble basic properties.

**Oxidation of Amido-oreinol.**—The reaction in this case is more complicated and depends upon the relative proportions of amido-oreinol and alkali present. If to an aqueous solution of 1 mol. of amido-oreinol hydrochloride is added a solution of 2 mols. of caustic soda, oxidation takes place in the air in two or three days; ammonia is developed and the solution shows a deep violet colour with a reddish tone; on the addition of sulphuric acid pale red plates are precipitated consisting of a mixture of two colouring matters.

If, however, the proportion is three or more molecules of caustic soda to one of amido-oreinol hydrochloride, the solution after oxidation is red with a yellowish tone, and on the addition of sulphuric acid, a mixture of three colouring matters is precipitated, of which one can be separated from the other two by extraction with benzene. The author is at present engaged in the investigation of these colouring matters.—R. B. B.

*Anthranilic Acid, Derivatives of.* H. Rupe. Ber. 30, 1097—1100.

*Nitro-anthranilic Acid* cannot be obtained by direct nitration, an acetyl group must first be introduced and nitro-acetyl-anthranilic acid is then prepared by careful treatment at a low temperature with nitric and sulphuric acids. In deacetylising this product, unless great care be employed, the carboxyl group is split off and paranitraniline formed. To obtain the result desired, the nitro-acetyl derivative is boiled with concentrated hydrochloric acid, when, on addition of water, a substance separates out which on crystallisation from boiling water forms yellow needles of nitro-anthranilic acid (nitro-amido benzoic acid, 5:2) with a melting point of 263° C., and identical with the compound prepared by Hübner from nitrosalicilic acid, ether, and ammonia. This compound possesses very feeble basic properties but it may be readily diazotised and the diazo compound conjugated with phenols or amines, when colouring matters are obtained dyeing similar shades to those yielded by analogous dyestuffs from paranitraniline, but possessing the property of dyeing with mordants by virtue of the carboxyl group which they contain. A specially useful colouring matter is obtained by coupling with amido-naphthol disulphonic acid II, the dyestuff yielding on cotton, with iron mordant a dull olive, with aluminium a pale mauve, and with chromium a full mauve.

*Effect of Phenylhydrazine on m-nitro-o-chlorbenzoic Acid Ethyl Ether.*—1 mol. of this ether (formed by passing hydrochloric acid gas into an alcoholic solution of the acid) is warmed for some hours on the water-bath with 3—4 mols. of phenyl-hydrazine. The dark red mass is crystallised from boiling alcohol, and yields, on cooling, fine needles of nitro-phenyl-indazolone. On concentration of the mother-liquor, long golden yellow needles of nitrophenylhydrazido-benzoic acid ethyl ether are formed—

and this on warming with alkalis is converted into nitro-phenyl-indazolone—

This compound dissolves readily in alkalis, and from a concentrated solution in caustic soda the sodium salt crystallises in red plates with a green reflex which possess distinct dyeing properties. Unmordanted wool is dyed a yellowish-green, and wool mordanted with chromium a yellowish brown.—R. B. B.

#### PATENTS.

*New Colouring Matters [Yellows, Browns]. Manufacture or Production of.* Levinstein, Ltd., and I. Levinstein, Manchester. Eng. Pat. 7596, April 10, 1896.

ALSO DYESTUFFS obtained from dihydroxy and dihydroxy-sulphonic acids of the naphthalene series are converted into their nitroso compounds yielding nitroso-azo dyestuffs

which dye chrome mordanted fibres yellow to brown shades, fast to light and milling. They also dye animal fibres from an acid bath. The diazo compound from 14 kilos. of *p*-nitraniline is combined in a weak acetic acid solution with 26.2 kilos. of the sodium salt of dihydroxynaphthalene sulphonic acid R. When the combination is complete a solution of 7.5 kilos. of sodium nitrite is added and the whole is run into 30 kilos. of hydrochloric acid (20° B.) diluted with water and cooled. After stirring for about 12 hours the new dyestuff is salted out. An analogous dyestuff is obtained by converting dihydroxynaphthalene sulphonic acid R into its nitroso compound, and after adding sodium carbonate, running in a solution of diazobenzene. In place of this latter, the diazo compound from either  $\alpha$ - or  $\beta$ -naphthylamine or from *p*-amidonaphthol sulphonic acid may be employed, the resulting dyestuffs giving reddish-brown, brown, and deep-brown shades on wool from an acid bath, or deep brown to black-brown shades respectively on chrome mordanted fibres.—T. A. L.

*Production of Dyes [from Cotton-Seed Oil], Impts. in.* L. P. Marchlewski, Manchester, E. S. Wilson, Strood, and E. Stewart, London. Eng. Pat. 9477, May 5, 1896.

DILUTE alkaline solutions extract from crude cotton-seed oil, a colouring matter for which the name gossypol is proposed. This may be isolated by precipitation of the fatty acids present in the solutions by appropriate metallic salts, followed by treatment of the residual liquors with an acid like hydrochloric acid, to decompose the alkali compounds left, the colouring matter being then precipitated in the form of flocks. It may be purified by repeated crystallisation from acetic acid and alcohol, and forms yellow crystals, easily soluble in alcohol, ether, boiling acetic acid, and aqueous alkali solutions, but insoluble in water.

Condensed with nitroso-dimethyl- and nitroso-diethyl-aniline in alcohol or acetic acid, gossypol yields dyestuffs which dye from an acetic acid or alcoholic solution, cotton and wool mordanted with iron, chrome, or tin, yellow-brown or brown. The dyestuffs are insoluble in water. Soluble derivatives, suitable for dyeing mordanted wool, are produced on sulphonating them. With  $\alpha$ -nitroso- $\beta$ -naphthol and  $\beta$ -nitroso- $\alpha$ -naphthol in concentrated sulphuric acid at a temperature of 55°—75° C., gossypol reacts, giving compounds which dye mordanted, and to some extent, unmordanted wool, brown.—E. B.

*Basic Colouring Matters [Blues], Impts. in the Manufacture of.* Read Holliday and Sons, Ltd., and H. Dean, Huddersfield. Eng. Pat. 11,309, May 23, 1896.

THE patentees propose to substitute diamido-diphenylmethane for aniline in the rosaniline blue process, and state that the dyestuffs produced, although similar in shade, possess different properties, their hydrochlorides being more soluble in water and have a greater affinity for cotton fibres. A mixture of 600 lb. of diamido-diphenylmethane, 100 lb. of rosaniline base, and 7 lb. of benzoic acid is heated to 160° C. for several hours, until a sample shows a pure greenish-blue colour. The melt is then purified by dissolving in dilute hydrochloric acid and precipitating the dyestuff with salt. The excess of base may be recovered from the mother-liquor by the addition of alkali. Another method given is to heat 500 lb. of diamido-diphenylmethane, 100 lb. of aciline salt or hydrochloride of the methane base, with either 100 lb. of amido-azobenzene or with 100 lb. of benzene-azo- $\alpha$ -naphthylamine to 160° C. The reaction is finished in the first case when a sample dissolves in dilute hydrochloric acid with a bluish-grey colour, and in the second, when it dissolves to a green solution in concentrated sulphuric acid. The purification of the dyestuff is carried out as in the first example.—T. A. L.

*Colouring Matters [Cotton Greys, Browns, Blacks], Impts. in the Production of.* Read Holliday and Sons, Ltd., Jos. Turner and Jas. Turner, Huddersfield. Eng. Pat. 11,370, May 26, 1896.

ACCORDING to the specification, dyestuffs as indicated in the title are formed by heating with sulphur and sodium sulphide, benzene or naphthalene sulphonates or their

homologues, sulphonated nitroso-hydroxybenzene or naphthalene derivatives or their homologues and diamido-naphthalenes and their sulphonic acids, either alone or mixed with any of the following substances; phenols, naphthols, their nitro or nitroso, amido, amido hydroxy or dihydroxy derivatives, amido, amido hydroxy or dihydroxy derivatives of nitro or nitroso phenols or naphthols or sulphonic acids of any of the foregoing. A mixture of 3 kilos. of sulphur, 20 kilos. of sodium sulphide, and 1 kilos. of benzene disulphonic acid is heated in an iron vessel at  $220^{\circ}$ — $320^{\circ}$  C. for about 4 hours, until no increase in the strength of the colour is observed. The melt forms a black mass soluble in water, and dyes cotton drab shades from a hot or cold bath. For the 4 kilos. of benzene disulphonic acid may be substituted, the same weight of any other sulphonic acid above named, or 2 kilos. of a sulphonic acid and 2 kilos. of a phenol, naphthol, &c. The dyestuffs obtained may be purified by dissolving and precipitating in the usual manner. They are employed for dyeing purposes preferably in presence of sodium sulphide.—T. A. L.

*Polycazo [Cotton Brown] Dyestuffs.* S. Pitt, Sutton. From L. Cassella and Co., Frankfort-on-Maine, Germany. Eng. Pat. 12,142, June 3, 1896.

In tetra-azo compounds of the formula—

it is found the diazo group I acts much more strongly than the diazo group II, a property of which advantage is taken in the manufacture of certain trisazo compounds derived from paradiamines, as benzidine, *o*-tolidine, dianisidine, *p*-diamido-diphenylamine, and 1,3'- and 1,2'-naphthylamine sulphonic acids, and other dyestuff components.

It has been ascertained that after the diazo group I is saturated, the diazo group II can be combined with amines, which, in consequence of their susceptibility to the action of nitrous acid, would be affected by re-diazotisation, were they first combined, along with one of the naphthylamine sulphonic acids above mentioned, with a tetrazotised paradiamine.

Among the trisazo compounds obtainable as a result of this discovery, those which are produced by the combination of diazo group I with phenol and that of diazo group II with Chrysoidines and Vesuvines are of special technical value. As an example: benzidine (18.4 parts) is tetrazotised and combined with 1,3'-naphthylamine sulphonic acid (22.3 parts). The intermediate compound obtained, is diazotised, the solution made slightly alkaline with sodium carbonate, and phenol (9.4 parts) added. After 5—10 minutes, the solution is rendered slightly acid, and Bismarck Brown (40 parts) is added. The dyestuff forms immediately. It dyes unmordanted cotton a brown colour very fast to light.

The azo compounds derived from *m*-phenylenediamine and the diazo compounds of sulphanilic acid, naphthionic acid, amido-salicylic acid,  $\gamma$ -amidonaphthol sulphonic acid, and 1,1'.3.3'-amidonaphthol disulphonic acid, employed in the above reaction in place of Bismarck Brown, give dyestuffs which dye unmordanted cotton respectively yellow-brown, cinnamon-brown, red-brown, and dark brown.—E. B.

*Violet [Azo] Dyestuffs suitable for Dyeing Wool, Production of.* S. Pitt, Sutton. From L. Cassella and Co., Frankfort-on-Maine, Germany. Eng. Pat. 12,556, June 8, 1896.

Azo-colouring matters, fast to acids and alkalis and unusually so to light, are produced by the action of diazotised 1,1'-amidonaphthol sulphonic acids on secondary  $\alpha$ -naphthylamines. Thus, a colouring matter dyeing wool violet from an acid bath, is obtained by diazotising 1,1'.3.3'-amidonaphthol disulphonic acid (32 parts) at  $10^{\circ}$ — $15^{\circ}$  C., and adding, at about  $60^{\circ}$  C., a solution of ethyl- $\alpha$ -naphthylamine hydrochloride (prepared from 18 parts of the base). Analogous compounds are obtained from the 2,4- and 3',4-disulphonic acids of 1,1'-amidonaphthol and from methyl- $\alpha$ -naphthylamine.—E. B.

*Cotton Colouring Matters [Yellow-Orange], The Manufacture and Production of New.* A. G. Green and A. R. Wahl, Manchester. Eng. Pat. 12,922, June 11, 1896.

By the action of caustic soda lye on *p*-nitrotoluene sulphonic acid, Walter, in 1883, showed that condensation products were formed, which dyed unmordanted cotton, orange-yellow shades fast to light (Bull. Soc. Ind. Mulhouse, 1887, 99). These products are known commercially as Sun Yellow, Curcumine S, and Direct Yellow G. According to Eng. Pat. 2664 of 1888 (this Journal, 1889, 41), by performing this condensation in presence of oxidisable substances, the dyestuffs known as Mikado Orange and Mikado Brown are produced. It was subsequently shown that these are reduction products of the first condensation products and can be obtained from them according to Eng. Pat. 23,672 of 1892 (this Journal 1893, 1023). A similar dyestuff is obtained (Eng. Pat. 16,708 of 1893; this Journal, 1894, 801) by oxidising dimodostilbene disulphonic acid with alkaline hypochlorites. A great similarity to all these substances is shown by the dyestuffs known as Oxypheine, Chloramine Yellow, and the like, which are obtained by the action of alkaline oxidising agents on dehydrothiolutidine sulphonic acid and primuline. The patentees have discovered an intermediate series of dyestuffs by condensing *p*-nitrotoluene sulphonic acid with a dehydrothio compound by means of weak aqueous caustic soda. The products formed dye unmordanted cotton, orange-yellow shades fast to light, chlorine, alkalis, and acids. When these new products are subjected to the action of reducing agents they are converted into new dyestuffs giving bright orange shades on unmordanted cotton and possessing the same valuable properties as the foregoing. The following quantities are employed in the first method:—A solution containing 28 lb. of sodium *p*-nitrotoluene sulphonate (85 per cent.) and 17 lb. of sodium dehydrothio-*p*-toluidine sulphonate in 10 gals. of water, is heated with 0.5 gal. of caustic soda lye (24 per cent. NaOH) for 3—4 hours at  $90^{\circ}$ — $100^{\circ}$  C. The product separates as a bright orange precipitate and is filtered and dried. It dyes unmordanted cotton a bright orange-yellow fast to light, chlorine, alkalis, and acids. It is less soluble than curcumine and can be readily salted out. Dilute hydrochloric acid completely precipitates it from its aqueous solution, whilst curcumine under similar conditions gives no precipitate. It is further distinguished from curcumine in being readily soluble in a strong solution of sodium bisulphite. In order to convert it into its reduction product, 50 lb. of the dyestuff obtained according to the previous example, are dissolved in 80 gals. of water together with 2 gals. of caustic soda lye. A solution of 10 lb. of glucose in 10 gals. of water is then added and the mixture is boiled until a sample dissolves in concentrated sulphuric acid, with a blue colour. After salting out, the product is filtered and dried. It forms an orange-brown powder and dyes unmordanted cotton reddish-orange shades fast to light, alkalis, and acids. Its aqueous solution gives a reddish-brown precipitate with dilute acids, whilst Mikado Orange under similar conditions gives a brownish solution but no precipitate. The shade can be varied by employing a different quantity or different quantities of the reducing agent.—T. A. L.

*Azo-Colouring Matters, Impts. in and connected with.* I. Levinstein and Levinstein, Ltd., Manchester. Eng. Pat. 14,144, June 26, 1896.

According to Eng. Pat. 22,641A of 1891 (this Journal, 1893, 258), the 1,1'-naphthylamine sulphonic acid cannot be used as a "middle component" in place of  $\alpha$ -naphthylamine. Similarly, in Eng. Pat. 2789 of 1892 (this Journal, 1893, 143), it is stated that of the naphthylamine sulphonic acids which Clève obtained from naphthalene  $\beta$ -sulphonic acid, only the  $\beta$  and  $\delta$  acids were suitable. The patentees confirm these statements so far as they relate to the tetra-azo derivatives of benzidine and its homologues, but find that the same restrictions do not apply when *p*-phenylene diamine is employed. Tetra-azo dyestuffs may be obtained from *p*-phenylene diamine either by means of *p*-nitraniline or *p*-amido-acetanilide, the azo compound obtained being

reduced or hydrolysed respectively. The diazo compound from 13.8 kilos. of *p*-nitraniline is run into a neutral solution containing 24.5 kilos. of the sodium salt of 1.1'-naphthylamine sulphonic acid. The nitro-azo dyestuff is filtered off and the press cake dissolved in 300 litres of hot water together with soda or other suitable alkali, and reduced by adding sodium sulphide. The colour changes from blue-violet to orange-red, and the reduced azo dyestuff, which may be salted out, becomes soluble in dilute hydrochloric acid. It is diazotised with 11.4 kilos. of sodium nitrite and 10 kilos. of hydrochloric acid (20 B.), forming a sparingly soluble brown powder, which is added to an alkaline solution of 48 kilos. of  $\gamma$ -amidonaphthol sulphonic acid. After stirring for 12 hours, the mixture is heated to 60° C., salted out, filter-pressed, and dried. The dyestuff gives deep indigo-blue shades on un mordanted cotton, dyes wool deep black from an acetic acid bath, and may be further diazotised and combined on the fibre.

—T. A. L.

**Colouring Matters [Browns: Blacks] from Dinitronaphthalenes.** *The Manufacture and Production of* B. Willeox, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 20,250, Sept. 12, 1896.

AN extension of Eng. Pat. 7765 of 1896 (this Journal, 1897, 436) applying the process there described to 1.4'-dinitronaphthalene. About 200 kilos. of this substance, 200 kilos. of grape sugar, 800 litres of water, 520 kilos. of caustic soda lye (24 per cent. NaOH), and 550 kilos. of sodium bisulphite solution (40 per cent. NaHSO<sub>3</sub>) are heated on a boiling water-bath until the dinitronaphthalene is dissolved. After adding 10,000 litres of hot water the solution is filtered and acidified with 700 kilos. of hydrochloric acid (32 per cent. HCl), boiled and allowed to cool, when the dyestuff separates as a blackish-brown powder, which dyes wool brown from an acid bath. By employing mixtures of 1.4'- and 1.1'-dinitronaphthalene, shades varying from violet-black to black may be produced, and the treatment with bisulphite and the reducing agent may be either simultaneous as in the example given or consecutive.

—T. A. L.

**New Colouring Matters [Hydrazone Compounds] of the Triphenyl Methane Series, and the Method of Producing the same.** J. Ville, Paris. Eng. Pat. 27,775, Dec. 5, 1896.

Rosolic acid (10 kilos.), hydrazine sulphate (13 kilos.), and caustic soda (4 kilos.) are heated together at about 100° C. for 24 hours, giving successively a red, then a blue, and, finally, a violet colouring matter. Methyl- and ethylhydrazine may be employed in place of hydrazine. The colouring matters formed are of the same class as those described in Eng. Pat. 16,039 of 1896 (this Journal, 1897, 437), and are similarly applied in dyeing.—E. B.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

**Silk Weighting in Switzerland, Regulations concerning.** *Färber Zeit.* 8, [10], 161—162.

THE silk weavers of Zürich have entered into an agreement with the Swiss silk dyers which forbids the weavers to import or to use, and the dyers to dye, any silk, whether of home or foreign origin, that has been weighted to such an extent as to seriously impair the strength of the fibre, on pain of heavy fines. The agreement is for one year, dating from April 1, and its conditions are to be rigorously enforced.—I. S.

**Silk Weighting in Germany.** *Leipziger Färber- u. Zeugdr.* Zeit. 46, [6], 243. (See also preceding abstract.)

FOLLOWING the example of the Swiss silk weavers and dyers, with respect to the limits of the weighting of silk, the silk dyers of Crefeld have entered into an agreement which stipulates that the maximum degree of weighting for taffetas in the future shall be 30—40 per cent., and for other kinds of silks 50—60 per cent. The majority of German dyers and manufacturers are said to have promised their adherence to this regulation.—I. S.

**Silk, The Finishing of.** H. Silbermann, *Färber Zeit.* 8, [9], 136—137.

IN many cases the appearance or "feel" which silk material is to have, is determined by the treatment of the yarn. Such goods are merely cleaned or scoured after leaving the loom, to fit them for the market. A piece that requires to be dressed receives for a soft finish a dressing with a composition consisting of starch or dextrin, gelatin, glycerin, and emulsified oil. The relative proportion and consistence of the preparation varies according to the quality of the cloth. For a stiffer finish the dressing employed consists of starch, soluble glass, and gelatin. For a very stiff finish the goods are first padded with a silicate of soda solution and tannin, and after a heavy squeeze, receive a dressing composed of dextrin, silicate of soda, gelatin, and emulsified oil. The dressing should be coloured the same shade as the silk to which it is to be applied.

—I. S.

**Wool, Scrooping and Lustreing.** E. Thiele, *Färber Zeit.* 8, [8], 120—121. (See also this Journal, 1896, 589—590; 1897, 41.)

TO obtain a maximum of scroop and lustre with a minimum of discoloration the author recommends the following processes, the quantities given being in each case for 10 kilos. of knitting yarn:—

(1) *For Light Shades.*—1.5 kilo. of bleaching powder in 500 litres of water, to which are added 1.5 to 2 litres of concentrated hydrochloric acid. The yarns are worked in this bath for 30 to 45 minutes at 60°—70° C.

(2) *For Dark Shades.*—3 kilos. of bleaching powder and 1.5 litre of concentrated hydrochloric acid in 500 litres of liquor. The goods are worked for 45 minutes at 50° C.

(3) *For Light or Dark Shades.*—To 400 litres of a solution of bleaching powder of  $\frac{1}{2}$  B., 3 litres of concentrated hydrochloric acid are added, and in this the goods are worked for 30 minutes at 50° C. For light shades the yarn is bleached with an aqueous solution of sulphurous acid.

The goods are "soaped," either before or after dyeing, for 10 minutes at 50° C., with 2 grms. of soap and 12 c.c. of sulphuric acid per litre.—I. S.

**Silk Weighting, Estimation of.** *Leipziger Färber- u. Zeugdrucker Zeit.* 46, [6], 259.

See under XXIII., page 564.

## PATENTS.

**Material suitable for Belting, Carding Cloths, Soles of Boots, and like Uses; Impts. in the Manufacture of.** F. W. Oliver, London. Eng. Pat. 10,104, May 12, 1896.

THE material described, consists of two or more layers of cotton, jute, or other fabric saturated with and cemented together by liquid celluloid. When an asbestos fabric is employed, the material may be used as a packing for joints. —R. B. B.

**Waterproof Fabrics, Impts. in the Manufacture of.** F. W. Oliver, London. Eng. Pat. 10,105, May 12, 1896.

IN the case of certain fabrics, e.g., stockinettes, which are too elastic and porous to admit of a thin film of celluloid being directly formed upon them, a transfer paper is first coated with celluloid solution, the film being then moistened with solvent and applied to the surface of the fabric, after which the paper is washed away.—R. B. B.

**Material suitable for Floor Coverings and other Industrial Purposes, New or Improved Process for the Production of.** H. Karle, Seekenheim, Germany. Eng. Pat. 2934, Feb. 3, 1897.

CELLULOSE, which must be free from acid, is worked up with an equal bulk of linen or cotton fibre into a thin pulp. The pulp is poured upon a fine sieve, a fleece of raw cotton or cotton wool is spread over it, and on this another layer of pulp. The slab, thus formed, is pressed between rollers, dried by heat, rolled upon a drum between steel wire webbing, and saturated with a jelly made from hair and calcium sulphohydrate (CaH<sub>2</sub>S<sub>2</sub>), then dried and again pressed. When dry, the material is felled or milled with

soap powder, treated with alkaline lye, dried, further treated with casein and borax, or with glycerin and lead oxide, and finally passed between calendering rollers.—R. B. B.

**Artificial Silk Thread, Impts. in the Manufacture of, and Apparatus therefor.** R. W. Strehlenert, Stockholm. Eng. Pat. 3832, Feb. 12, 1897.

A DEFECT in the apparatus hitherto used for the manufacture of artificial silk is that, whenever a thread breaks between the mouthpiece and the bobbin on which the fibre is wound, it is necessary to stop the working of the apparatus. According to the present improvement several fibres are pressed out from a series of mouthpieces to a common point under water, where they are twisted together before being wound on the bobbin. The mouthpieces are attached to one or more cylinders, which receive a rotary motion in a horizontal plane, and motion in a similar direction is imparted to the water into which the threads are passed. It is claimed that by this device a broken thread is immediately caught up by an adjacent strand, and that uninterrupted working of the apparatus is thus secured.—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

**Dyeing Process, A Contribution to the Study of Reactions in.** M. A. Reyehler. Bull. Soc. Chim. 1897, 17, 449—455.

WHEN wool which has been well scoured and washed, is boiled in water, the liquid is found to be neutral to litmus and phenolphthalein, but gives a brown coloration with Nessler's reagent, and on distillation yields an alkaline distillate containing ammonia; there appears, therefore, to be present in the liquid, either an organic ammonium salt or an amido compound.

In the author's experiments, the same sample of wool was repeatedly boiled in water, and the various resalting liquors examined in several respects. The water originally possessed an electrical conductivity of 3—4 millionèmes; i.e., 1 c.c. offered a resistance between  $\frac{10^6}{3}$  and  $\frac{10^6}{4}$  Siemens units. After boiling 72 grms. of wool in a litre of water, the conductivity had increased to  $393 \times 10^{-6}$ ; the residue from evaporation of this liquid contained lime, magnesia, potash, soda, and traces of silica, alumina, and ferric oxide; whilst one-half of the liquid yielded after distillation 0.045 gm. of ammonium chloroplatinate. After boiling five times in fresh water, the conductivity of the final bath was  $45 \times 10^{-6}$ , and the amount of ash was greatly reduced. Treatment with water at 75° C. twice repeated, reduced the conductivity of the liquid to  $19 \times 10^{-6}$ . Half the sample of wool was then treated with  $\frac{1}{1000}$  normal hydrochloric acid at 75°, and the other half dyed in a solution of magenta of corresponding strength. In the first case, the conductivity of the bath was  $58 \times 10^{-6}$ , in the second case  $61 \times 10^{-6}$ —a very slight difference. Probably in dyeing, the Rosaniline hydrochloride is at once dissociated, the base combining with certain groups in the keratin molecule, and the acid behaving as if in the free state.

Widely divergent results are obtained by the treatment of wool with dilute hydrochloric acid, and by the addition of this acid to the water in which wool has been digested; for, whereas in the former case the conductivity of the acid liquid is reduced from 160 to 60 units, in the latter case it is not sensibly diminished, the bases present in the liquor apparently not sufficing to neutralise the acid. The conductivity of 60 units shown by the liquid in which wool has been treated corresponds to that of solutions of certain metallic chlorides of corresponding strength ( $\frac{1}{1000}$  normal), the acid in this case being apparently entirely neutralised by the bases extracted from the wool.

When the amount of hydrochloric acid in these liquors is estimated by means of silver nitrate, it invariably appears greater than should theoretically be the case, and the author attributes this to precipitation by silver nitrate of some extractive principle of the wool.—R. B. B.

**Dyeing of Cotton Yarn, Recent Progress in.** Oesterr. Wollen- u. Leinen-Ind. 1897, 113.

Two interesting processes of recent introduction are those by which "screop" and a silk-like lustre may be imparted to cotton yarn. To obtain "screop," the yarn, after dyeing, is worked successively in baths containing calcium acetate, soap, and an organic acid (acetic or tartaric), and finally dried without washing. For the production of a silky lustre, the cotton is mercerised in a stretched condition, according to the process of Thomas and Prevost (this Journal, 1896, 804).

A very important discovery is that of the production of a blue on cotton, which is said to be fast to bleaching, i.e., to the action of chlorine. This is effected by means of Alizarin Blue F (Meister, Lucius, and Brünig), a highly purified product, applied to cotton mordanted with Turkey-red oil and chromium oxide; after dyeing, the yarn is steamed, washed, and soaped.

The use of Paranitriline Red is rapidly extending, especially since it has been established that good results may be achieved without the use of ice. To effect this, sodium acetate must not be added to the diazo solution until the latter is required for use, and with this precaution the solution may be preserved for three days at 22° C. without decomposition.

A recent advance in the price of Aniline salt causes the competitors of Aniline Black among the direct colours to be regarded with special interest. Fast Black B (Badische Anilin u. Soda Fabrik) is dyed cold in as concentrated a liquor as possible, with the addition of an amount of sodium sulphide equal to the weight of the dyestuff. The yarn is entirely immersed in the bath for an hour, then washed several times with water, worked at 50° C. in a bath of alum and acetic acid, and shaded, if desired, with a little Methylene Blue, after which it is treated with copper sulphate to increase the fastness to light, and finally soaped. The colour is very fast to washing and to acids, but rubs off slightly; it appears very suitable for warp-dyeing. Other direct blacks are Diaminogene B (Cassella), Dianil black (M. L. and B.), Benzo-chrome black (Bayer), and Diamine jet black Cr (Cassella), the two latter being treated with potassium bichromate after dyeing. All these blacks are still somewhat dearer than Aniline Black, but this is partly counterbalanced by their greater ease of application, and the fact that they in no way impair the useful properties of the fibre.

The blue dyed with Diaminogene Blue and Diamine Azo Blue (Cassella) is proving a useful substitute for indigo, but its progress is hindered by the fact that many conservative consumers insist upon regarding the "rubbing-off" test as the only indication of the fastness and desirability of a blue colour—a relic of the days when indigo was practically without a competitor.

As regards machinery, there is little progress to report during the past year. The dyeing of cops makes but slow headway, and appears to be profitable only when the dyers are also manufacturers, and large quantities of standard shades are required.—R. B. B.

**Imitation Gold Thread, A Cause of Oxidation of [and Tendering].** L. Vignon. Bull. Soc. Chim. 1897, 17, 441—443.

For the production of imitation gold thread, a fine metallic ribbon, consisting of a core of copper coated with brass, is wound around a cotton thread which has been dyed yellow. These threads frequently become black or tarnished, and this may arise either from atmospheric causes or from acids or acid salts being left in the cotton fibre after dyeing. Tarnishing has, however, occurred in cases where it could not possibly be attributed to either of the above causes, and the author has traced the defect to the presence of common salt in the dyed cotton. He considers that the copper-zinc couple formed by the metallic ribbon may set up electrolytic decomposition of the salt, and that the liberated chlorine or hydrochloric acid either acts directly upon the metal, or the chlorine in conjunction with atmospheric moisture brings about oxidation. He therefore recommends that in dyeing thread intended for this purpose, salt should invariably be replaced by sodium sulphate.—R. B. B.

*p*-Nitraniline Red, Discharging finished. H. Schmid.  
Färber Zeit. 8, [10], 149—152.

Hitherto white or coloured effects on a *p*-nitraniline red ground were produced by means of resists; that is, substances which decomposed the diazo compound (e.g., stannous salts, alkaline sulphites, &c.), with or without the addition of some dyestuff, were printed on the naphthol-prepared fabric before passing the same through the developing bath. This process, however, has many defects. The coloured designs are not fast, and cannot be fixed by subsequent steaming; and, for the sake of the white, the oil, which is essential for obtaining a bluish red, has to be omitted from the naphthol solution. The red is in consequence of a yellowish hue, which is turned yellower still by the action of the tin salt on the diazo solution of the developing bath. On account of these and other defects the want of a process that would make it possible to discharge the developed red, made itself felt. But the ageocies and methods in common use for discharging azo colours were found to be inadequate for this purpose. The destruction of *p*-nitraniline red by reduction and splitting up of the compound into *p*-phenylenediamine and amidonaphthol according to the equation—

presupposes an energetic source of hydrogen, not available by hitherto known methods.

But if a substance having a solvent action on the colouring matter be added to the reducing agent, the action of the hydrogen is considerably augmented. Such a substance is glycerin, in which the *p*-nitraniline red dissolves off the fibre on heating, but still more readily during steaming. Thus, by adding glycerin (or a glyceride) to a stannous salt of an organic acid, a perfectly white discharge on *p*-nitraniline red can be obtained. For this purpose the quantity of glycerin need not be large, as its action is continuous, dissolving fresh portions of red so soon as the part in solution has been reduced.

The process is as follows:—The discharge composition, consisting of an organic stannous salt, glycerin, and a thickener, is printed on the ready-dyed cloth in the usual manner, dried, and passed through a steam ager (5—7 minutes) at the maximum steam pressure. The ager must be free from oxygen; hence in presence of aniline black as part of the design, the goods are allowed to hang over night in an oxidation chamber at 36°—40° C. before steaming.

After steaming, the goods are immediately passed through a tepid acid bath (40 grms. of strong hydrochloric acid per litre) to remove the *p*-phenylenediamine and amidonaphthol formed during the process, and are then well washed to remove all traces of tin.

Where there is a white discharge only, the goods may with advantage be passed through an acidified solution of bleaching powder, whereby the white is still further improved, whilst the red not only does not suffer, but is brightened by chlorination.

The process is not applicable for discharging  $\alpha$ -naphthylamine clarets, but can be used for the other analogous azo colours produced on the fibre.—I. S.

*Aniline Black, The Influence of Lime Stains on.* R. J. Flintoff. J. Soc. Dyers and Colourists, 1897, 107—108.

The author has observed, in some cases, stains on aniline-dyed cloth, owing to the imperfect development of the black. On examining the cloth, he found it to contain lime, which acted as a resist. Subsequent experiments have shown that small traces of lime are sufficient to prevent the complete development of the black.—I. S.

*Benzochrome Black for Cotton Warps.* Heinrich. Färber Zeit. 8, [8], 118—119.

The author recommends this dyestuff as a substitute that may be used for aniline black for the dyeing of cotton warps which are to be woven together with undyed wool.

The colour of such warps must be fast enough to stand the subsequent process to which the cloth has to be sub-

mitted during the dyeing of the woollen parts; and benzo-chrome black is said to answer every requirement. It is dyed at a boiling temperature with 5 per cent. of anhydrous sodium sulphate and 2 per cent. of soda ash. The goods are subsequently treated in a separate bath, at a temperature of 80°—90° C., with 2—3 per cent. of potassium bichromate, 2 per cent. of copper sulphate, and 1 per cent. of acetic or  $\frac{1}{2}$  per cent. of sulphuric acid.—I. S.

*Chromium Mordant [on Cotton]. An Improved.* E. Knecht. J. Soc. Dyers and Colourists, 1897, 108—109.

SODIUM or potassium bichromates, as such, are useless for the mordanting of cotton. Gatty, by passing cotton impregnated with potassium bichromate through an atmosphere of sulphur dioxide, obtained a precipitation of chromium hydrate on the fibre. Scheurer and Blondel (this Journal, 1892, 33—34) first suggested the use of sodium thiosulphate as a reducing agent along with potassium bichromate in the presence of excess of ammonia. The pieces are padded in this mixture, dried, and steamed under pressure for one to two hours. Subsequently Prud'homme, and simultaneously the author, made the observation, that in presence of ammonia a chromate and a sulphite have no action on each other; as soon, however, as the ammonia is volatilised, reduction takes place, and chromium hydrate is precipitated. Relying on this fact, H. Koechlin, at the author's request, has worked out the practical process, which is as follows:—Potassium bichromate, 50 grms.; sodium bisulphite of 56° Tw., 100 grms.; ammonia, 100 grms., in one litre. Pad in this solution, dry, steam for two minutes in a rapid ager, and wash. W. H. Gardner obtained much better results than with the above by increasing the bisulphite to 260 grms., the other proportions remaining the same. Excellent shades, it is said, are obtained in dyeing with alizarin colours on this mordant; but in most cases some lime salt should be added to the dye-bath.—I. S.

*Orycellulose, A Curious Formation of.* E. Knecht. J. Soc. Dyers and Colourists, 1897, 109.

If calico be first mordanted with chromium, and then treated warm, along with ordinary calico, with a 3 per cent. solution of hydrogen peroxide in presence of ammonia or caustic soda, the chromium hydrate rapidly dissolves, forming the yellow chromate; the mordanted material at the same time becomes more and more tender, until disintegration sets in, whilst the other unmordanted piece is not materially affected. If both pieces be steeped in methylene blue, the tendered one dyes a full shade, whilst the other is only tinted. These facts point to the formation of oxycellulose, but the author was unable to find an explanation why this substance should be formed in the one case and not in the other.—I. S.

*Lactic Acid as an Assistant in Wool Chroming.* P. Fuchs. Färber Zeit. 8, [9], 133—135. (See also this Journal, 1897, 140.)

The author confirms the statement of C. Dreher (Färber Zeit. 7, 233) and of C. Areher (this Journal, 1897, 140), that satisfactory results are obtained with lactic acid only in the presence of sulphuric acid. The proportions recommended are 1.5 per cent. of potassium bichromate, 3 per cent. of lactic acid, and 1 per cent. of sulphuric acid of 66° B. In view, however, of the fact that by this method the chromium oxide goes too quickly on to the fibre, thereby involving the risk of unevenness, the author recommends the use of "lactoline," which is a mixture of 1 mol. of potassium lactate with 1 mol. of free lactic acid ("bilactate"); the method of application remaining the same as before.—I. S.

*Gums for Thickening.* C. Gassmann. Färber Zeit. 8, [9], 135.

See under XVI., page 548.

*Waste Water from Print Works, The Purification of.* R. J. Flintoff. J. Soc. Dyers and Colourists, 1897, 99.

See under XVII. B., page 551.

## PATENTS.

*Bleaching Certain Vegetable Fibres, more especially those of the Urtica Family; Impts. in.* A. F. B. Gouess, London. Eng. Pat. 10,936, May 21, 1896.

THE fibres are immersed, first in a solution of a hypochlorite of an alkali or alkali earth, at 3—8 ll. for 1—10 minutes, and then in nitric acid at  $\frac{1}{2}$ —3 Tw. for 1—5 minutes, or in these solutions in the reverse order. After the treatment, the fibres are well washed in water in the usual manner.

—E. B.

*Dyeing, Bleaching, Washing, and Rinsing Wound Yarns [Cop. Dyeing Apparatus], Impts. in Apparatus for.* G. Linkmeyer, "Herford," Germany. Eng. Pat. 8125, March 30, 1897.

Cops on hollow perforated spindles, are affixed to an air-tight cylinder, which is provided around its entire circumference with oblique perforations for their reception. The spindles are secured in position by a casing, which slides round them from below, causing them to be displaced

slightly upwards. In this way they hold the casing without further means of attachment being required. The cylinder and cops along with the casing are enclosed in a tank, which is filled with water, &c. to a height above the highest position reached by the piston.

When the piston is moved, the action is similar to that of a double-acting pump; thus, on the downward stroke of the piston, the liquid in the bath passes through the perforations (above the piston) from the tank into the cylinder, whilst underneath the piston the reverse action takes place.

The motion of the piston is arrested at each end of the cylinder for an interval of time, the duration of which is determined by the length of curved slots in a crank crosshead.—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Citric Acid, Preparation of, by Fermentation.* Zeits. f. Spiritusind. 1897, 20, 149.

IN the German Patent, No. 72,957, of April 5, 1893 (see this Journal, 1894, 57, 80, 275, 772), the preparation of citric acid by fermentation of carbohydrates is claimed, and species of *Citromyces* are especially mentioned as bringing about this fermentation. The patent is now supplemented by a new claim (Ger. Pat. 91,891) based upon the discovery that the same result may be obtained by means of *Mucor piriformis*. The latter fungus is found on putrefying fruit, especially on pears and apples; its spore carriers only grow in a moist atmosphere, and form long white filaments, terminated by brownish-black heads. It can readily be obtained in pure culture by sowing the spores in a suitable medium, such as sugar solution, beer wort, steamed rice, starch paste, &c., the ordinary room temperature being favourable for its growth. The solution becomes acid from the formation of citric acid.—A. K. M.

*Freezing Points of Dilute Sulphuric Acids.* W. Hillmayer. Monatsh. f. Chem. 18, 27—30.

PFANDLER and Schnegg, in 1875, and later, Pictet (this Journal, 1895, 35), have investigated this subject. The starting result of Pictet—that acids containing 6.77 per cent. and below, of  $H_2SO_4$ , freeze above 0° C.—induced the author to repeat his determinations. Six mixtures of the concentrated acid and water were made, containing, as nearly as possible, 1, 2, 3, 4, 5, and 6 per cent. of  $H_2SO_4$ , and their exact composition ascertained by analysis. The freezing points of these acids were then determined with great care, and the results compared with those of Pfandler and Schnegg by means of the interpolation curve which those authors deduced from their results. The following table shows the close agreement of the present results with those older ones, and proves the error of Pictet's work with acids of similar strengths:—

Per Cent. $H_2SO_4$ .	Freezing Point observed. °C.	Freezing Point interp. (P. and S.)	Difference.
1.95	-0.78	-0.74	+0.04
3.00	-1.16	-1.16	0.00
4.01	-1.65	-1.60	+0.05
5.13	-2.05	-2.12	-0.07
6.02	-2.55	-2.58	-0.03
8.02	-3.61	-3.69	-0.08

If the molecular weight be calculated from the depression of the freezing point according to Raoult's method, the six acids give values very close to 49, and if the freezing points be then re-calculated from a molecular weight of 49, the following figures are shown:—

Per Cent. $H_2SO_4$ .	Amount of $H_2SO_4$ to 100 $H_2O$ .	Molecular Weight calculated from Depression of Freezing Point.	Depression of Freezing Point		Difference.
$H_2SO_4$ .			Observed.	Calculated from Molecular Weight 49.	
1.95	1.99	48.4	0.78	0.770	+0.010
3.00	3.09	50.6	1.16	1.198	-0.038
4.01	4.18	48.1	1.65	1.611	+0.049
5.13	5.41	50.1	2.05	2.067	-0.017
6.02	6.41	47.1	2.55	2.483	+0.067
8.02	8.72	45.9	3.61	3.583	+0.027

The agreement is very close, though it is difficult to explain the half molecular weight.

Pfandler and Schnegg tried to calculate that hydrate, the assumption of the presence of which in their solutions would make the freezing-point curve a straight line. They found that this would be, for strengths up to 12½ per cent.  $H_2SO_4$ , 10.309  $H_2O$ . If from the author's results the

molecular weight be calculated on the assumption that the acids are mixtures of water with the hydrate  $\text{H}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$  the results agree nearly with the half molecular weight 139; but on now re-calculating as before the depression of the freezing point from this molecular weight, the agreement is seen to be reasonably close only in the case of the very dilute acids:—

Amount of $\text{H}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ to 100 $\text{H}_2\text{O}$ .	Depression of Freezing Point		Difference.
	Observed.	Calculated.	
5.850	0.78	0.801	- 0.021
9.293	1.16	1.270	- 0.100
12.844	1.65	1.756	- 0.106
17.000	2.05	2.329	- 0.279
20.610	2.55	2.817	- 0.267
29.455	3.61	4.026	- 0.416

So that the assumption of the existence of this hydrate in solution is not borne out by the application of Raoult's method.—J. T. D.

*Double Chromates.* J. Zehener. *Monatsh. f. Chem.* **18**, 48—55.

A BOILING solution of potassium bichromate, neutralised with sodium carbonate, and then evaporated, first over a flame and then *in vacuo* over sulphuric acid, gave plates or columns, yellow in colour, having a specific gravity of 2.719 at 15° C., soluble in water to the extent of 64.2 parts in 100 at 14° C., losing no weight at 150°—160°, and giving, on analysis, figures expressed by the formula—

The same salt was obtained by Hauer by spontaneous evaporation of mixed solutions of potassium and sodium chromates, and also by Rose, who melted together potassium bichromate and sodium carbonate. Further evaporation of the mother-liquor from the above salt gave a crop of fragile crystals, sp. gr. 2.575, of which 100 parts of water at 14° dissolve 66.4 parts, and which proved to be the same salt with half a molecule of water of crystallisation. On longer standing a third crop was obtained, of yellow needles, very soluble, of the formula  $\text{Na}_2\text{CrO}_4 \cdot 4\text{H}_2\text{O}$ . The yield was respectively about 40 per cent., 30 per cent., and 20 per cent. of the weight of the potassium bichromate used. A comparison of these results with Johnson's method of preparing sodium chromate, by the evaporation at the freezing point of a mixture of potassium bichromate and sodium carbonate, shows that temperature has an important influence on the reaction.

A strong solution of ammonium bichromate was neutralised with potassium carbonate at the ordinary temperature, the liquid filtered and mixed with a large excess of 95 per cent. alcohol, and the crystalline precipitate rapidly filtered and washed with alcohol, and purified by solution in a little water and reprecipitation by alcohol. The yellow, very soluble fine needles thus obtained have a specific gravity of 2.403, and give figures indicating the formula  $3\text{K}_2\text{CrO}_4 + 2(\text{NH}_4)_2\text{CrO}_4$ . On boiling their solution in water, ammonia is given off, and a mixture of potassium chromate and bichromate remains.

Substituting sodium for potassium carbonate in the last case, small prismatic readily soluble crystals, of sp. gr. 1.842, are obtained, the formula of which is  $\text{NaNH}_4\text{CrO}_4 \cdot 2\text{H}_2\text{O}$ . This salt loses all its water *in vacuo* over oil of vitriol, and the dried salt is stable in the air at the ordinary temperature, but, on heating, readily gives off water and ammonia, leaving sodium bichromate.

Lithium carbonate, added at the ordinary temperature to potassium or to ammonium bichromate, gives in neither case any double salt. But when lithium carbonate is used instead of sodium carbonate in the first-described experiment, there separate after a certain amount of potassium chromate and bichromate, golden-yellow needles, so unstable as to be very difficult to dry. The analytical figures agree very closely with the formula—

and the specific gravity of the salt is 2.539.—J. T. D.

*Cyanides, Conversion of Nitrites into.* W. Kerp. *Ber.* **30**, 610—612.

CONVERSION of nitrite into cyanide was observed during a separation of cobalt and nickel by means of potassium nitrite in acetic acid solution when the alkaline filtrate of cobalt-potassium cyanide was accidentally evaporated to dryness over the open flame.

The formation of cyanide was traced to the interaction of acetate and nitrite, and the author has accordingly studied the decomposition which occurs when these salts are heated together.

He has found that a mixture in molecular proportions of fused sodium nitrite and sodium acetate explodes violently when heated, but that the reaction proceeds quietly when to this mixture is added an equal weight of soda. Such a mixture (12 grms. sodium acetate, 10 grms. sodium nitrite, and 22 grms. of sodium carbonate), when heated, begins to soften and swell out at 300°; at 375° it loses water and considerable quantities of hydrocyanic acid. So soon as the temperature of reaction is reached a strong glowing is observed, but there is neither explosion nor spurting. The product of the reaction is porous and friable, and, owing to separated carbon, is dark-coloured. The cyanide of sodium may be obtained pure by extraction with 70 per cent. alcohol and recrystallisation.

The reaction is represented by the following equation:  $\text{CH}_3\text{COONa} + \text{NaNO}_2 = \text{NaHCO}_3 + \text{NaCN} + \text{H}_2\text{O}$ , which the author considers to occur with the intermediate formation of nitroso-acetic acid,  $\text{NO} \cdot \text{CH}_2 \cdot \text{COONa}$ .

The yield obtained varied with the manner of heating, but in no case amounted to more than 25 per cent., as calculated from the above equation.

Experiments in which sodium nitrite was heated with organic salts other than the acetate, showed that both sodium propionate and neutral sodium tartrate gave rise to cyanide, but that in the case of sodium formate the product consisted entirely of sodium carbonate.

With potassium nitrate, sodium acetate reacts violently when the two salts are melted together. On moderating the reaction by the addition of the double amount of sodium carbonate, a product consisting essentially of carbonate, is obtained, but mixed with this are small quantities of cyanide and larger quantities of cyanate. In this and other cases in which hydrocyanic acid results during the oxidation of organic substances with nitric acid, the author considers the result to be due to the intermediate formation of nitrous acid.—J. T. C.

*Bromides and Iodides of the Alkalis, Preparation of.* J. Knobloch. *Pharm. Zeit.* **42**, 190—191; *Chem. Centr.-Bl.* 1897, [1], 850—851.

See under XX., page 553.

#### PATENTS.

*Caustic Alkalis, A Process for Obtaining or Extracting from Alkaline Aluminates, and Hydrate of Barium and Alumina from Barium Aluminate.* D. A. Péniaokoff, Huy, Belgium. *Eug. Pat.* 10,252, May 13, 1896.

CLEAR aluminate lyes are briskly agitated for a considerable time, whereby about four-fifths of the alumina present is precipitated. The lye drawn off, containing all the alkali, is then treated with a "quantity of alkaline earths equivalent to the amount of alumina remaining behind in the solution." The cleared caustic alkali solution is then decanted, evaporated, and melted down. Barium hydroxide may in like manner be obtained from barium aluminate.—E. S.

*Sulphur, Impts. in Recovering from Sulphuretted Hydrogen.* J. Broek and F. Hurter, Liverpool. *Eug. Pat.* 13,844, June 23, 1896.

SULPHURETTED hydrogen is mixed with sulphurous acid in the proportions indicated by the equation—

and the mixture is passed into a Claus kiln, previously strongly heated. In practice, an impure hydrogen sulphide, such as that produced by treating alkali waste with lime kiln gases, is mixed with sulphurous acid obtained by the

combustion of iron pyrites or zinc blende, in such proportions that the free and combined oxygen present may be just sufficient to combine with the hydrogen of the hydrogen sulphide. If the sulphurous acid gas contain arsenic, it is purified before use by cooling, and then passing through a coke scrubber washed with sulphuric acid. The kiln is fed at first with a mixture of hydrogen sulphide and air, until the requisite temperature is reached, when the above described gaseous mixture is introduced. The kiln needs to be protected against loss of heat by radiation during the reaction. The sulphur produced, flows out from the Claus kiln into the sulphur pan.—E. S.

*Brine and other Solutions, Impts. in Evaporating, and in Apparatus therefor.* E. J. Baill and J. Brock, Liverpool. Eng. Pat. 14,951, July 6, 1896.

The brine is pumped into an upright tubular heater, supplied with steam from the evaporator, and passes into a second similar heater, divided by a vertical partition plate into two compartments, in one of which the brine descends and in the other ascends, and passes from the latter into a chamber having a perforated plate at the bottom, this chamber being on the top of the evaporator—a tall vertical cylinder down which the heated brine passes in thin streams. A current of air is forced through a horizontal tubular heater into a jacket surrounding the lower part of the evaporator, into which it passes through a series of holes, meeting the descending spray of brine, and passing from the upper part of the evaporator into the first of the tubular heaters described, thus “securing a second effect,” as stated in one of the claims. The second tubular heater is heated from a separate source, as by the waste steam of an engine. The concentrated brine is received in a tank at the bottom of the evaporator, the tank extending outwards open to the air, so that the salts deposited therein may be withdrawn by hand; but the outer part of the tank is sealed off by a descending flange from the part immediately under the evaporator. The cooled brine is led into a second tank, from which, after addition of fresh brine, it is pumped through the system of heaters to be again concentrated.—E. S.

[*Alkali Percarbonates.*] *Chemical Products, Manufacture or Production of, by Electrolysis.* E. J. Constam and A. von Hansen, Zürich. Eng. Pat. 19,218, Aug. 31, 1896.

The method consists in electrolysing a saturated solution of a carbonate of an alkali metal or of ammonium at a temperature below 0° C. If a saturated solution, say of potash, made at -10° C. and cooled down to -16° C., be electrolysed, with or without a diaphragm, a bluish salt is obtained which is found to consist of percarbonate of potassium mixed with more or less potash or potassium carbonate, and to possess oxidising properties. The current strength employed may vary between 1 to 300 amperes per square decimetre of anode surface.—G. H. R.

*Ammoniacal Preparations [Liquid Ammonia and Camphor], Improved.* J. Pattison, Glasgow, N.B. Eng. Pat. 23,245, Oct. 20, 1896.

CAMPHOR, either in lumps, ground, or in alcoholic solution, is added to liquid ammonia to render the latter more detergent, and to confer upon it a more agreeable odour, &c.—E. S.

*Glover Towers, Gay-Lussac Towers, and the like: Impts. in, used, for instance, in the Manufacture of Sulphuric, Muriatic, and Nitric Acids.* P. Jensen, London. From G. Lunge, Zürich, Switzerland, and L. Rohrmann, Kranschwitz, Germany. Eng. Pat. 6916, March 16, 1897.

THE object of the invention is to compel the greatest possible amount of liquid to remain as long as possible in the apparatus, thus increasing the effect of the desired reaction, and reducing the height of the apparatus required, without diminishing the yield. To effect this, two new forms of insertion bricks are used. Each brick has a vertical through-slot surrounded on the top side by a

channel recess, the inner edge of the channel being shallower than the outer edge, so that, when the bricks are built in, merely the outer edge shall be touched by the brick lying thereon, but not the inner edge. There will thus be a free running over of the liquid from the channel, over the inner edge, down on to the next lower brick. To prevent the acid adhering to the under side of the bricks, they are formed with a V-groove or recess all round the slot. Both sets of bricks are of the same outer dimensions, but one set has a longer and narrower slot than the other, so that the length grooves are wider in the one set and the end grooves in the other. The two sets of bricks are placed in alternate courses, with ordinary acid-proof bricks between, in such manner that the liquid trickling from the upper course “runs down upon firm surfaces of the next following course.”—E. S.

*Glover Towers and the like, Impts. in.* P. Jensen, London. From L. Rohrmann and H. H. Niefenfuhr, Kranschwitz, Germany. Eng. Pat. 7127, March 18, 1897.

IN order to arrest the dust which deposits in a Glover tower where it first meets with solid surfaces and liquid, there is constructed above the gas inlet, and upon suitable girders, a nest of acid-proof bricks of about three courses, over which is a free space, and above that the girders on which the real filling devices are piled. Entry openings are provided in the part of the wall surrounding the free space, so that the dust-arresting bricks or other objects may be removed for cleansing, “without, as heretofore, removing the whole of the filling devices.”—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

*Hollow Glassware, Decorating and Colouring.* Central-Bl. f. Glas-Ind. u. Keramik, 12, 51 and 71.

Gilding was practised as far back as the 16th century, but the gold, being merely fixed on a substratum of sodium silicate by burnishing, was not durable. The modern method of applying the gold in the form of precipitate along with calcined borax and oil, and then firing at a suitable (“gold fire”) heat, is superior, but still the decoration is incapable of resisting various acids. The firing temperature is a most important factor, since if too low, the decoration is not fixed, and if excessive the gold is dull. Instead of burnishing the gilded surface with agate, the design is drawn on the glass with a flux of glass, minium, borax, and oil of turpentine, on which, when dry, the precipitated gold is applied, fired, and polished with a cloth.

*Painting.*—In this branch the sole progress is in the artistic character of the decorations, the colours and method of employment being the same as of old, viz., a glass flux coloured by metallic oxides and applied by a brush in a turpentine medium, the operation being completed by firing in the kiln. Grey is obtained by means of a mixture of iron oxide and cobalt oxide; green, by the addition of chromium oxide; azure blue, by cobalt oxide, chromium oxide, and aluminium hydroxide; coffee-brown, by iron oxide, zinc oxide, cobalt oxide; orange, by red iron oxide; yellow, by sulphur preparations; red, by gold.

*Engraving.*—The older industry of grinding glassware has greatly declined, most of the modern ground glassware being of ordinary glass (not lead glass, as formerly), and artistic designs have been abandoned as less profitable than simple work. Engraved work commands a higher price for the finer specimens. The sand-blast is also used both for fine designs and ordinary engraved work.

*Spun glass decorations* can be applied to all descriptions of glassware, the articles being covered by threads of spun glass of various colours, applied by a machine which can be adjusted so as to lay the threads on at any desired distance apart. This method, combined with cameo decorations, is capable of wide application for glass services. The cameos are prepared by mixing equal parts of unburned porcelain earth and burned Revere clay in warm water to a paste, which is then left for three or four weeks (but stirred three or four times a week to insure intimate mixture), and then cast into the cameo mould. After removal from the mould, the cameo is slowly dried by

exposure to the sun for a week, and gradually fired, commencing in the cooling kiln. The cameo may be coloured by the application of finely powdered coloured glass to the fresh, moist surface.

**Opal Glass.**—A mixture of barium nitrate, strontium nitrate, and stannous chloride is applied to the surface of a red hot glass plate, and the glass to be opalised, being held over the evolved fumes, assumes a number of beautiful blue-red shades. If previously converted into ice-glass by quenching in water, the effect of opalising will be heightened.

**Ice-flower glass** is prepared by dull-grinding the surface of the vessel, applying a coating of glue mixed with resin, and leaving to dry in a cool place; the contraction of the glue in drying, producing fractures in the dulled surface which resemble ice crystals.—C. S.

*Pottery and Porcelain, Researches on.* E. Damour.

Enli. Soc. d'Encouragement, 1897, 191—215.

SOME of the greatest of the practical difficulties encountered in the potter's art are due to the difference of the coefficients of expansion of the biscuit and the glaze. If the coefficient of the glaze be greater than that of the biscuit, the ware is liable to become cracked or "crazed"; if, on the other hand, the coefficient of expansion of the glaze be less, it is apt to scale. There are two possible means of obviating these defects, *viz.*: *First*, to use glaze and biscuit of nearly the same expansibility; *secondly*, to strengthen the glaze—*e.g.* by means of boric acid. The author considers that the true remedy for these difficulties is to be found in improved knowledge of the expansion coefficients of the materials used in pottery, and proceeds to describe the methods employed and the results obtained in his investigation. The preparation of prisms for measurement presents no difficulty in the case of biscuit, but it is otherwise with the glazes, which attack both platinum and porcelain vessels. Finally, the refractory material of the "Pasteur filter" was adopted, with the addition of a thin film of glaze. The expansion was measured by Fizeau's method (the displacement of Newton's rings) as modified by Le Chatelier. Figures are given in the paper showing the apparatus. In order that the rings may be visible, the bottom of the prism must be polished—a condition easily complied with in the case of the glazes, but which, with the biscuit, necessitates either the attachment of a microscope cover-glass by means of a film of balsam, or the addition of a thin layer of glaze. The author satisfied himself by trial with mixtures of known properties that it is sufficient to determine the law of expansion between 15° C. and 100° C., the values calculated by extra-polation being apparently correct to the limits of temperature attained in the kilns.

It has been found that the dilatation of the faience biscuit depends to a preponderating extent upon the fineness of grain and the physical condition of the materials. Small variations of chemical composition have, as a rule, but a trifling effect. The range of expansibility of the different materials employed, amounts to as much as 100 per cent.

In the case of the faience glazes also the range of expansibility is very great. The coefficient is, as a rule, greater than that of the biscuit. Alkalis, which increase the fusibility of the silicates, also increase the coefficient of expansion. The alteration of the superficial layer of the biscuit by the action of the glaze is *not*, in the author's opinion, an important factor in "crazing." He considers that this evil is to be combated in the porcelain manufacture "by the empiric study of the question under industrial conditions," and particularly the determination of the coefficients of expansion of the biscuit and of the glaze and the temperature of the kiln. In the case of *faience*, the greater range of variation of expansibility necessitates a more complete control of the operations through purely scientific study.—V. C.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### PATENTS.

*Vulcanite, Hard Woods, or other Hard Materials; The Manufacture of a New or Improved Substance or*

*Product suitable for Use as a Substitute for; or for other Uses or Purposes for which same may be applicable.* H. Birkbeck, London. From P. W. Wierdsma and J. Kuipers, Leeuwarden, Holland. Eng. Pat. 2677, Feb. 5, 1896.

This invention relates to a product made from the refuse of potato-flour manufacture. The refuse consists of 85 per cent. of water, 5 per cent. of peel, and 10 per cent. of cellular and fibrous material, and only the last is useful for this purpose. It is freed from the peel, dirt, &c., by washing, grinding, and sifting; is bleached or dyed, if required; and finally, it is moulded under pressure into sheets or blocks.—R. B. B.

*Cement, Plaster, Chalk, and the like; Improved Process and Apparatus for the Treatment of Articles of.* A. J. Boulton, London. From C. Tortorici and R. Grasso, both of Catania, Italy. Eng. Pat. 18,990, Aug. 27, 1896.

The articles are covered with warm tar or asphalt, and heated until the tar, &c. boils. The receptacle is finally closed hermetically. The volatile hydrocarbons are liberated in the process, and the articles become permeated with those which are less volatile.—V. C.

## X.—METALLURGY.

*Aluminium, Method of Browning.* [Protective Coat.]

Illustr. Zeit. f. Bleichind. 26, [13], 397.

To produce a brown surface on commercial aluminium, which is thereby protected against the action of moist air, water, and weak acids (*e.g.*, acetic acid), Götting employs a 1 per cent. solution of ammonia, either alone or in conjunction with about 4 per cent. of chloride, acetate, or other suitable salt of ammonium. In the former case the solution is rubbed over the aluminium, with which it combines, and in conjunction with the silica, iron, &c. present in the metal, forms a resistant surface (hydrogen being evolved). In the second method the metal is immersed for 1 to 3 hours, the aluminium and iron dissolved, being reprecipitated as hydroxides by the ammonium salts employed, the colour of the deposit in this case being darker than in the other.—C. S.

*Gold Mines of Galicia, in Spain, The.* Eng. and Mining J. 1897, 63, 400.

The gold is found in the north-western part of Galicia, between the slate and granite formations. The ore is an iron pyrites containing a little arsenic. The lodes run generally with the formation, north and south; they are well defined, and average about 14 ft. in thickness.

The following are the principal mines which are being developed:—

**Sagasta Mines.**—About 2,000 m. of levels and crosscuts have been driven to fully prove the lodes. Last year, 1,095 m. were driven and 1,600 tons of ore extracted, equal, according to the assays, to 1,425 oz. of gold.

**Fosas de Vila Mines.**—These mines have been proved by sinking pits. The ore assays to 0·8—1·0 oz. of gold and 20 oz. of silver to the ton, besides a considerable quantity of lead.

**Josefina Mines.**—These are of arsenical iron pyrites. The assays give over 1 oz. of gold and 2 to 30 grains of silver to the ton.

**Buena Esperanza.**—The main lode is over 2,000 m. long, about 4 ft. wide, and more than 100 m. deep. The assays give 0·45 to 0·5 oz. of gold per ton, with less arsenic and more iron than the Josefina ore.

**Virgen y S. Victor.**—These are two mines on the same lode, in which the ore, though very rich, is of a complex nature.—A. S.

*Gold from Cyanide Solutions, Precipitation of.* L. Ehrmann. Chem. and Metall. Soc. of S. Africa. April 17, 1897, 3—7.

The precipitation of gold from cyanide solutions by means of zinc, is found to be greatly assisted by converting the zinc shavings into a copper-zinc couple by immersing them

for a short time in an ammonio-cupric solution, and by using this couple at a temperature of  $80^{\circ}\text{C}$ . With a ratio of cyanide to gold ranging from 14:1 to 16:1 the cold-extraction in 24 hours increased from 61—93 per cent. to 95—98.8 per cent. of the gold present in the liquors by the substitution of the copper-zinc couple for zinc. The original solutions in this case assayed from 2 to 7 dwt. of gold per ton. As large a percentage of the gold was precipitated in two hours at  $80^{\circ}\text{C}$ . as in 24 hours in the cold by the zinc and the copper-zinc couple respectively. Even when the ratio of  $\text{KCy}:\text{Au}$  was 205.5:1, extractions of 86.3 and 84.2 per cent. of the gold present in a solution containing 1 dwt. 17 grs. per ton were obtained by means of the couple, acting for 24 hours in the cold and for two hours at  $80^{\circ}\text{C}$ . respectively.—W. G. M.

*Platinum-Silver Alloys: their Solubility in Nitric Acid.* J. Spiller. Proc. Chem. Soc. 1897, [180], 118.

REFERRING to the published statements in the text-books, and particularly to those in Percy's *Metallurgy* and Bloxam's *Chemistry*, according to which 5 or even 9 per cent. of platinum followed the silver into solution when their alloys were treated with nitric acid, the author investigated the properties of 10 graduated alloys, constituted as follows:—Series I., containing 12, 9, and 5 per cent. of platinum; series II., containing 2, 1.5, 1, and 0.75 per cent. of platinum; series III., containing 0.5, 0.4, and 0.25 per cent. of platinum. These alloys were prepared by fusion of the requisite proportions of silver and platinum under a gas-air blow-pipe flame in shallow porcelain cups and then attacking with nitric acid of three different strengths; it was thus found that the ordinary concentrated acid of 1.42 sp. gr., warmed, proved the best solvent, but that even under the most favourable conditions no more than 0.75 to 1.25, mean 1 per cent. of platinum, could be dissolved along with the silver.

When diluted nitric acid of 1.2 sp. gr. was employed, the maximum amount of platinum taken up was only about 0.25 per cent.; whilst the highly concentrated acid of 1.50 sp. gr. proved altogether inappropriate, giving a bulky insoluble product, consisting of platinum black, intermixed with nearly the whole of the silver nitrate formed.

It would appear, then, that Berthier's account, quoted by Percy, and the statement in Bloxam's *Chemistry* are incorrect.

*Iron Pyrites, On the Decomposition of.* W. A. Caldecott. Proc. Chem. Soc. 1897, [179], 100.

IN Watt's dictionary (1892 edition, vol. iii, page 64) it is stated that ferrous sulphide "is formed by the reduction of  $\text{Fe}_2\text{O}_3$  on ferric salts by decomposing organic matter in the presence of sulphates," also that "finely divided yellow pyrites ( $\text{FeS}_2$ ) oxidises in air forming chiefly  $\text{FeSO}_4$ ." T. K. Rose (*The Metallurgy of Gold*, 1896, page 343) states that " $\text{FeS}_2$  is oxidised by air and water,  $\text{FeSO}_4$  and free  $\text{H}_2\text{SO}_4$  being formed."

In the treatment of auriferous pyritic Witwatersrand conglomerate, a large percentage of the ore is reduced by wet crushing in the battery to an impalpable powder. This fine material constitutes "slimes," and is carried in suspension by water into extensive dams, where it settles. The slimes leaving the battery are free from ferrous sulphide, but this compound may be detected in them a few days after deposition in the dams. The settled slimes form a clayey mass, practically impermeable to air and water, and consequently subsequent oxidation of the ferrous sulphide to ferrous sulphate proceeds extremely slowly.

When iron pyrites are crushed to an impalpable powder in an iron mortar ferrous sulphide is formed.

It thus appears that ferrous sulphide and not ferrous sulphate may be the first product of the decomposition of iron pyrites.

Owing to the almost total absence of acidity in slimes deposited as above, even when containing 0.89 per cent. ferrous sulphide, it is probable that under these conditions  $\text{FeS}_2$  undergoes dissociation, and the sulphur is separated as such; the author is engaged in further investigating this subject.

*Lead and the Oxides of Sulphur, The Reactions between.* H. C. Jenkins and E. A. Smith. Proc. Chem. Soc. 1897, [179], 104—105.

THE authors draw attention to the fact mentioned by one of them during the discussion on Mr. Hannay's paper (this Journal, 1894, 812, also 639), that when lead is heated to high temperatures and a current of sulphur dioxide passed through it, lead sulphide and oxide are formed. They have conducted experiments with a view to see whether the observations accounted for the anomalies hitherto met with whenever a full explanation of the chemistry of lead smelting in the reverberatory furnace has been attempted. Mr. Hannay had sought to explain these anomalies by the assumption that a volatile compound,  $\text{PbS}_2\text{O}_2$ , was formed, basing his evidence on an observation that in some experiments of his where air was passed over heated galena, he only obtained one-half of the lead in the metallic state. He gave the equation  $2\text{PbS} + \text{O}_2 = \text{Pb} + \text{PbS}_2\text{O}_2$  as representing what occurred. The experiments have been carefully repeated by the authors, who find that the ratio of lead obtained to lead volatilised is not constant but varies, and is entirely dependent on the velocity of the current of air, indicating that no such reaction exists and that the ratio found in Mr. Hannay's experiments was the result of the accidental coincidence of his experimental conditions.

The authors, on continuing the experiments, found on heating lead sulphide and lead sulphate in a vacuum, that a reaction having sulphur dioxide as a product occurred, and they found that the amount of residual lead sulphide and oxide was dependent on the duration as well as on the temperature of the experiment. They then proceeded to separately test the pairs of bodies supposed to be present, with a view to discover if secondary or reversed reaction occurred. On heating lead and lead sulphate, they always obtained lead sulphate in the product in amounts varying with the duration of the experiment and the length of time that it occupied.

On heating lead and sulphur dioxide together, they found that at moderately elevated temperatures lead sulphide and sulphuric anhydride are formed in each other's presence, and that this leads to the formation, first of lead oxide and then of lead sulphate, the action being represented more or less completely by the equations  $\text{Pb} + 3\text{SO}_2 = \text{PbS} + 2\text{SO}_3$ ,  $\text{Pb} + 2\text{SO}_3 = \text{PbSO}_4 + \text{SO}_2$ , or more simply—

the main determining condition as to the relative amount of the products being that of the temperature at which the experiment is performed. One of the authors is continuing the investigation of the exact condition of the equilibrium.

The last of these equations occurring in the presence of excess of sulphur dioxide, is the exact inverse of the main ones of the metallurgy of lead as stated by Dr. Percy, and requires a supply of air by which to sweep away the sulphur dioxide as soon as it is liberated. The authors submit that, as the new equations quite account for the anomalies to which attention has been drawn, there is now no reason whatever to doubt that the equations given by Dr. Percy,  $\text{Pb} + \text{PbSO}_4 = 2\text{PbO} + \text{SO}_2$ ,  $\text{PbS} + \text{PbSO}_4 = 2\text{Pb} + 2\text{SO}_2$ , as well as  $\text{PbS} + 2\text{PbO} = 3\text{Pb} + \text{SO}_2$ , represent the facts and form the basis of the metallurgy of lead.

*Solid Alloys, X Ray Photographs of.* C. T. Heycock and F. H. Neville. Proc. Chem. Soc. 1897, [179], 105—106.

IN a previous communication (Trans. Chem. Soc. 1889, 55, 666), the authors discussed the behaviour of gold in sodium, and the state of the gold in the solid alloy. They have lately examined alloys of gold and sodium by cutting thin sections from cylinders of the alloy of various concentrations, placing these on a photographic plate, and photographing them by means of the X rays.

On account of the much greater transparency of sodium to these rays as compared with gold, the individual crystals of the alloy were clearly shown. The plates were about 12 mm. thick, and the alloy had been allowed to cool and solidify very slowly. Pure sodium shows no crystalline structure, but an alloy containing 3 per cent. of gold

shows a mass of transparent sodium crystals, with dark spaces between the crystals where the gold has concentrated during the process of solidification.

A 10 per cent. alloy of gold shows the same phenomena, but the crystals of sodium are narrower, and the dark spaces occupy a larger area.

The appearance of the sodium crystals strongly recalls the fern-like pattern seen when ammonium chloride is crystallised on a microscopic plate, doubtless due to the fact that sodium, like so many other metals, crystallises in the regular system. An eutectic alloy of gold and sodium (23·1 per cent. gold) shows, as one would expect, scarcely any structure, because the crystals of gold and sodium separate out simultaneously, and are too minute to be detected by such a method.

A solution obtained by saturating sodium with gold at a temperature considerably above the melting point of sodium, shows a net-work of black, opaque needles, which are no doubt crystals of gold which have separated and grown to a considerable size as the liquid cooled.

No sodium crystals are here visible, as the groundwork consisted of the eutectic alloy. The authors have been able to demonstrate the internal structure of a solid alloy, and to show that the process of solidification is strictly comparable to that of a saline solution, the details being perfectly visible to the naked eye.

*Gold, Liquefaction in Cyanide Bars.* F. Stockhausen. Chem. and Metall. Soc. of S. Africa, April 17, 1897, 10—13.

THE irregularity of assays when drill- or cutting-samples are taken from cyanide bars, is dwelt upon. The variation is sometimes due to imperfect mixing, sometimes to liquefaction. A dip-assay (from molten metal) alone is to be relied upon with this material. In the case of two bars exhaustively examined by means of carefully checked assays of the dip sample and of drillings and cuttings taken from different parts of the bars, the assays gave the following results:—

	Bar 1.		
	Average Assay.	Extremes.	Maximum Difference.

*Iron, Specific Heat of, at High Temperature; Note on.* W. N. Hattley. Iron and Steel Inst., May 1897. Ironmonger, 1897, 79, 358.

THE specific heat of iron increases at high temperatures in so remarkable a degree as to indicate a change in the molecular condition of the metal. From 0° to 660° C. the formula for the specific heat  $\gamma$  at temperature  $t$  is—

$$\gamma = 0.1012 + 0.000050666t + 0.000000163998t^2$$

At the ordinary temperature, Regnault and Ponceau have found the specific heat to be 0.11379; but at 750°—1000° C. it is 0.213, at 951°—1006° C. it is 0.218, and at 1050°—1200° C. it is 0.19887. These numbers, however, are not in accord with Hystrom's, which was 0.4031 for 1400° C.

—W. G. M.

*Crucible for Steel Melting, The Permeability of.* J. O. Arnold and F. K. Knowles. Iron and Steel Inst., May 1897; Ironmonger, 1897, 79, 317—318.

PURE Swedish iron was melted in clay pots, from 1 to 3 per cent. of aluminium was added, and the charges were then teemed. The resulting ingots were then broken up and re-melted, analyses of the metal being made before and after this treatment. It was found that the carbon percentage was increased from 0.04 to from 0.6 to 1 per cent., the silicon from 0.01 to from 0.04 to 0.5, and the sulphur from 0.01 to from 0.03 to 0.06 per cent. (the last-named proportion of sulphur being due to the use of a specially sulphury coke in melting), whilst the proportion of phosphorus had fallen from 0.02 to from 0.017 to 0.019 per cent., and that of aluminium from the percentage employed to from 0.07 to 0.2 per cent. At the same time the crucible became lined with a layer of alumina, shown at B in the annexed sketch, in which A represents the

steel, and C the clay wall of the pot. The explanation of the change is that the walls of the clay crucible are permeable at high temperatures, and that carbon monoxide penetrating into the metal became decomposed by the aluminium, which was thus separated as oxide, whilst the carbon of the gas served to carburise the iron; the sulphur contents of the steel were also increased owing to the penetration of sulphur dioxide into the crucible through the walls. The silicon was reduced from the clay of the pot. The loss of phosphorus is to be ascribed to the action of the basic (alumina) lining which had formed within the crucible. The oxidation of aluminium by carbon monoxide according to the equation  $2Al + 3CO = Al_2O_3 + 3C$  had been shown by Arnold in 1891.—W. G. M.

*Steel, The Carbide in.* F. Mylius, F. Foerster, and G. Schoene. Ber. 29, 2991—2996.

THE authors have examined cast and forged steels containing from 0.1 to 3.0 per cent. of carbon, with the view of settling the composition of the contained carbide of iron, as a preliminary to work upon the changes which take place during the hardening of steel. They prepared steels from electrolytic iron and carbon from acetylene, which were melted together in little porcelain retorts by an oxygen

blowpipe. The steels were heated for four hours to low redness, cut into strips about 2 mm. thick, and submitted to a process of solution.

Electrolytic solution, making the metal the anode in a solution of zinc sulphate, was not found suitable; it is difficult to avoid electrolysis of the carbide itself, and oxidation easily takes place, either atmospheric or through too high current density, contaminating the residue with carbonaceous substances.

The same oxidation readily takes place when the iron is attacked by chromic and sulphuric acids; and the best method is to use dilute acid.

The following results were arrived at by using dilute hydrochloric, sulphuric, or acetic acid:—

1. Cast and forged steel contain the same carbide, which forms gleaming needles and plates, up to 1 mm. long. Arnold and Read's amorphous carbide was never seen.

2. The whole of the carbon may be present as carbide.

3. The residue of carbide is slowly soluble in dilute acids.

4. The yield depends on the nature and concentration of the acid, as the following figures (steel containing 1.3 per cent. of carbon) show:—

Acid.	Yield of Carbide per Cent. of Steel.	Percentage of Carbon in Carbide.
4 x normal HCl.....	5	6.42
2 x " " ".....	8	6.50
1 x " " ".....	15	6.71
4 x " H <sub>2</sub> SO <sub>4</sub> .....	12	6.71
1 x " " ".....	17	6.64
1 x " HClO <sub>4</sub> .....	19-20	6.50

5. The carbide is a definite compound, Fe<sub>3</sub>C, existing as such in the steel, and which undergoes no change during isolation. Its constancy of composition was proved by fractional solution of the steel.

6. The carbide dissolves completely in warm hydrochloric acid, evolving gas, which is chiefly hydrogen (92.3 H, 1.4 N, 6.3 CxHy in one case: the hydrocarbon probably pentane). Liquid hydrocarbons may be also separated, but any solid residue means impurity in the carbide.

7. The carbide is not acted on by water at the ordinary temperature. Steam at 140° and above, forms Fe<sub>3</sub>O<sub>4</sub>, and gives off combustible gases; at a red heat, hydrogen and oxides of carbon are found in these gases, but no marsh gas.

8. The dry carbide is unalterable in the air (though under circumstances not yet defined, it is pyrophoric).

9. The moist carbide is easily oxidised by free oxygen or other oxidising agents, giving ferric hydroxide and a brown amorphous substance containing carbon hydrogen and oxygen.

10. The carbide melts unchanged, and, at a higher temperature, breaks up into carbon and a carbide containing about 4.6 per cent. of carbon.

The authors consider they have proved the identity, and the existence in steels, of Fe<sub>3</sub>C, a body analogous to, but more stable than Mn<sub>3</sub>C. They consider any statement as to its constitution premature. They mention that crystals found and described by Weinschenk in 1889 in a meteoric iron from Magura have been recently analysed by Cohen, and found to have the formula Fe<sub>3</sub>C and the properties above described, and point out that microscopic research on steels is leading to the opinion that the carbide in all steels is identical. They suggest tentatively that the breaking up of the carbide above its melting point, and the consequent formation of lower carbides, may play a part in the hardening of steel.—J. T. D.

*Cast-iron, Malleable.* G. P. Royston. Iron and Steel Inst., May 1897. Ironmonger, 1897. 79, 338-340.

HARD, brittle, white-iron castings may be softened either by oxidising the carbon or by changing it into the graphitic state. The former (Reaumur's) method is most generally used, and consists in heating the castings in oxide of iron (or in lime, sand, or bone-ash, in the presence of air); but in this case manganese and sulphur must be absent or else the elimination of carbon will be delayed. When

oxide of iron is used for annealing, it is in part reduced to the metallic state. The process is necessarily slow, because the carbon has to travel to the outside of the bar before it becomes oxidised; this it does by diffusion, and more rapidly as the temperature is raised. The temperature must not exceed 1,000° C. lest the castings become deformed; and, on the other hand, as carbon does not exist in solution at temperatures below 660° C. any oxidation of the carbon would then be accompanied by oxidation of iron. The quickest result obtained was with a bar of white iron  $\frac{1}{2}$  in. in diameter, which was decarburised after heating to 900° C. for 22 hours. The second process consists in merely heating the iron continuously to from 850°-650° C. It is accidentally applied, sometimes, in the cooling of large pieces of iron which have escaped complete decarburisation by the Reaumur process. The rationale is explained in a second paper on the Relation of Carbon to Iron (see succeeding abstract). Castings produced by this method are as soft as those obtained by Reaumur's process, but the presence of the free carbon as finely divided graphite prevents bending. Here the action is independent of the size of the casting, and large masses may be softened as rapidly as smaller pieces, the quickest result being the conversion of a white iron containing 3.8 per cent. into one with only 0.6 per cent. of combined carbon, within five hours. A new method of annealing is also described. The material is simply packed in a non-oxidising substance, and is thus heated to the freezing point of the metal (which is about 35° C. below the fusing point); it is thus instantaneously converted into a steel containing 1.5 per cent. of carbon, the remainder of the carbon being separated throughout the mass in the form of graphite. Care must, of course, be taken not to raise the temperature too high, or the iron will melt. The presence of manganese, tin, or chromium interferes with this reaction, but that of silicon, aluminium, or nickel is without effect. The author hopes shortly to be able to produce a soft iron containing graphite with the same speed as in the case of the steely material just described.—W. G. M.

*Iron, Relation of, to Carbon at High Temperatures.*

G. P. Royston. Iron and Steel Inst., May 1897. Ironmonger, 1897. 79, 340-343.

WHEN high and low carbon steels, placed in contact, were heated to 900° C. for 12 hours in a vacuum porcelain tube, it was found that carbon had been transferred from the former to the latter in such a way that the loss of weight of the one corresponded exactly to the gain of the other, whilst the variations in the carbon percentages agreed exactly with the alterations in weight. This tends to confirm the view that the carbon is present in iron at a red heat in a state of simple solution. The explanation of the behaviour of white iron in the malleable cast-iron process would then be as follows:—White iron in the cold is a mixture of mass cementite and pearlite (cementite and ferrite). When heated to the recalescence point AR, the cementite begins to decompose, and the iron dissolves the released carbon to the extent of 0.9 per cent. The pressure of this dissolved carbon then prevents the further dissociation of the carbide. As the temperature rises the solvent power of the iron increases, and at 1,030° C. it can dissolve 1.5 per cent. of C. But at this critical temperature the whole of the residual cementite decomposes, in spite of the carbon pressure around: the iron cannot, however, dissolve more than 1.5 per cent. of C at this point, and the remainder of the carbon is therefore deposited as graphite as fast as it is separated. When fluid (white) cast-iron is quenched, the bulk of the carbon forms cementite, and 1.5 per cent. remains as a homogeneous alloy with the rest of the iron; but when the iron is heated to 700° C. and quenched, the well-recognised alloy corresponding in composition to Fe<sub>3</sub>C (containing 0.9 per cent. C) is formed. In white iron at a red heat there are two opposing pressures: the dissociation pressure of the carbide, and the solution pressure of the carbon. The latter is normally the greater; but if the latter be removed, or if the former be aided, the decomposition may be continued. The tendency to crystallisation appears to be the only other force operative at this temperature. The crystallising point of pure iron is 750°; in

0.2 per cent. C steel it is  $735^{\circ}$ ; and in 0.8 per cent. C steel it is  $685^{\circ}$  C. ( $AR_1$ ). It would appear, therefore, that  $AR_2$  in low carbon steels marks the crystallising point of the pure iron, while the presence of carbon in solution prevents crystallisation of the remaining iron until the point  $AR_1$  is reached, at which the carbon passes out of solution into combination with iron as  $Fe_3C$ . Hence, in 0.2 per cent. C steels at  $720^{\circ}$  C., the mass should consist of pure crystallised ferrite intermixed with amorphous masses of iron containing carbon. The solution pressure of carbon in iron appears to exceed the "crystallisation pressure" of the iron. To sum up:—The pressure of carbon in solution is greater than either the dissociation pressure of  $Fe_3C$  or the crystallisation pressure of Fe alone, but less than that of the two pressures acting together. In the absence of tendency to crystallisation of Fe (i.e., above  $750^{\circ}$  C.), slow cooling will not cause any deposition of graphite. In the absence of dissociation pressure (that is, if the iron contain less than 0.9 per cent. C) graphite is not produced by annealing. Below  $620^{\circ}$  C. it may be assumed that carbon is unable to combine with iron, for a malleable cast-iron containing the whole of its carbon as graphite, underwent no change even when heated for three hours to that temperature. And below  $AR_1$  all the carbon other than graphite exists as  $Fe_3C$ , so that no diffusion of carbon can occur, and hence no oxidation of carbon can take place without a simultaneous oxidation of carbon.—W. G. M.

*Open-Hearth Process, Combined, of Bertrand and Thiel: Notes on.* E. Bertrand. Iron and Steel Inst., May 1897. Ironmonger, 1897, 79, 329–332.

In this process (this Journal, 1897, 243) two furnaces are employed at different levels. In the first much, but not all, of the phosphorus is eliminated from the charge; the fact that it is not necessary to remove the whole in this furnace permits the use of less lime, and therefore of less slag in the first hearth, so that the flame acts upon the metal with greater intensity than it could otherwise do. The scrap is for the most part charged into the second, and the silicious and phosphoric pig iron into the first furnace, ore and lime being added to each as required. It is even possible to work with pig iron alone, whether high or low in silicon, the only provision being that the material should contain but little sulphur. When large proportions of pig iron are used, the hearth should be deeper than usual, because the ore and basic addition are more bulky, and because the boiling of such a charge is more lively than under the older system of working. Under somewhat unfavourable conditions, several charges of grey forge-pig, containing 3.8 per cent. C, 1.0 per cent. Mn, 1.6 per cent. P, and 1.0 per cent. Si have been worked by this process, magnetic Gellivara ore, with about 65 per cent. of Fe, being used in boiling. The finishing furnace was used only for finishing the heat, a small quantity of scrap being melted in it merely that it should not be empty whilst heating up. After treating several 12-ton charges of the forge-pig in the primary furnace, the average composition of sample ingots run as the metal was being transferred to the second hearth, was 2.2 per cent. C, 0.4 per cent. P, 0.05 per cent. Si, and 0.05 per cent. Mn. Hence one-third of the carbon and three-fourths of the phosphorus, with practically the whole of the silicon and manganese, are removed in the primary furnace, the behaviour of the phosphorus being the reverse of that in the basic Bessemer process. Owing to the length and low gradient of the ladder connecting the two furnaces, it was unsafe to reduce the proportion of carbon and phosphorus below that given above, as the metal would then have flowed too sluggishly. The time required in the primary furnace was about  $1\frac{1}{2}$  hours, and in the finishing furnace about 2 to  $2\frac{1}{2}$  hours; and there was, in the majority of cases, a gain in the actual weight of metal, ranging from 0.1 to 6.2 per cent. In no case was there a loss of more than 2.4 per cent.; this is due to the fact that the metalloids in the pig iron reduce more than their own weight of iron from the ore during their oxidation. It is believed that working with two primary furnaces to one finishing hearth, with the same pig as in these experiments, nine 15-ton heats could be made in 24 hours; and that by charging liquid pig iron the output

could be still further very greatly increased. The slags from the primary furnace are very rich in silica (25–30 per cent.), and contain also about 13–14 per cent.  $P_2O_5$ , whilst those from the finishing hearth contain a larger proportion of lime in order to ensure complete dephosphorisation. Tables of analyses and tests of the charge and of the finished steel are supplied. An addendum has also been given, showing the result of working two heats of basic pig, containing 3.8 per cent. of C, 2.5 per cent. of P, 1 per cent. of Si, and 0.6 per cent. of Mn, with 2 tons of Gellivara ore and 1 ton of lime. After treatment in the primary furnace, the metal contained 1.2 per cent. of C, 0.55 per cent. of P, 0.03 per cent. of Si, and 0.05 per cent. of Mn; whilst the slag contained 19.6 per cent. of  $SiO_2$  and 21.88 per cent. of  $P_2O_5$ , with only 6.34 per cent. of Fe. This slag could evidently be employed as a fertiliser.—W. G. M.

[*Iron.*] *Cold-Shortness, Influence of Phosphorus on.* H. Jüptner von Jonstorff. Iron and Steel Inst., May 1897; Ironmonger, 1897, 79, 347–351.

THE author seeks to account for the varying influence of phosphorus on iron under different conditions. Pig irons containing phosphorus evolve a portion of this element in the form of hydrogen phosphide ( $PH_3$ ) on treatment with dilute acids, but much is at the same time left in the residues as iron phosphide ( $Fe_3P$ ). When manganese is present in considerable quantities, however, the proportion of phosphorus as insoluble phosphide rapidly increases with that of manganese, in accordance with the formula  $Mn_3P_2$ . The phosphorus from pig iron is left by cupric chloride solutions as a pulverulent crystalline admixture, whilst the ground-mass is poor in phosphorus. Thus the phosphorus favours crystallisation in the less fusible constituents by the formation of easily fusible compounds, and these, being the last to solidify, do not separate in large crystalline planes. The author has now investigated the gases evolved by the action of dilute  $H_2SO_4$  (sp. gr. = 1.1) at  $18^{\circ}$  C. on samples of steel, by passing them through Peligot tubes containing neutral silver nitrate solution; after acting in the cold, the solution was raised to the boiling point, and then air was drawn through the whole. It is thus shown that the cold-shortness of the metal increases with the proportion of the phosphorus that is evolved as hydrogen phosphide. Many specimens of steel showed no trace of cold-shortness, although their total percentage of phosphorus was higher than that of other steels which were markedly cold-short; in such cases the proportion of phosphorus given off as  $PH_3$  was highest in the more brittle metals. It would seem that the phosphorus present as  $Fe_3P$  or  $Mn_3P_2$  is practically without influence upon the properties of the metal, being distributed through the mass in the form of crystal grains, which only affect to some extent the machining of the metal owing to their hardness. Manganese, by assisting the formation of these crystals, therefore tends to counteract the prejudicial influence of phosphorus. The phosphorus, on the other hand, that is present in the ground mass in solution, and that is evolved as  $PH_3$ , is in a position to affect the character of the whole of the material. Further experiments with weld-iron confirmed this observation, and seemed to establish the fact that the quantity of separated phosphide ( $Fe_3P$ ) in the metal is greater in the case of annealed metal, but less in the hardened material, than in the normal or "natural hard" iron. It would thus appear that, like carbon, phosphorus exists in iron in two conditions—as "hardening" (that which gives rise to  $PH_3$ ) and as "phosphide" phosphorus, and that the inter-conversion of the two varieties takes place in a manner similar to that of the two carbon modifications, only that it is slower and less far-reaching. Behrens and Van Linge's view that the deposition of the phosphide takes place within the carbide is also supported. Since the hardening capacity of steel is reduced by an increase in the percentage of phosphorus, it appears that the latter element favours the separation of the carbide; but, on the other hand, the influence of the phosphorus increases with the proportion of the combined carbon. Conversely, however, carbon would seem to favour the separation of phosphide; and the phenomenon of cold-shortness is not solely dependent upon the quantity of hardening phosphorus present. It is necessary to take into

account the joint quantity of the carbides and phosphides present, or, in other words, the quantity of the eutectic alloy of the metal cooling from fusion, inasmuch as with an increasing quantity of the mother-metal the formation of crystals is facilitated in the portion of the iron that is first to solidify. Following up the idea of eutectics in the solidification of steel ingots, the material consists of crystals deposited from without inwards, with interspaces and cavities filled with the portion last separated. But on further cooling, there separates from this solidified solution either the solidified solvent, if the solution be dilute, or the dissolved material (carbide, phosphide, &c.) if it be concentrated. Thus each constituent of iron may exist in at least two different forms: carbon, phosphorus, and sulphur occurring in two, chromium in three, and manganese, tungsten, &c. in several different forms. The chief of these are:—(1.) *Dissolved Substances separated out from Concentrated Solutions*—e.g. graphite, ferrochrome, carbide, &c., which are always characterised by a more or less well-defined crystalline form. (2.) *The Solvent separated out from Dilute Solutions*—e.g. pure granular iron; these are always crystalline, but less definitely so than the members of Class 1. (3.) *Solidified Mother-Metal*, in which secondary separations occur. If  $\text{Fe}_3\text{P}$  and  $\text{Mn}_3\text{P}_2$  have higher melting points than the final residue of the mother-metal, and are relatively but little soluble in this, the process of solidification may again reverse, and phosphides may separate once more, together with some carbide (corresponding to water of crystallisation in saline solutions); but as the whole mass must solidify shortly afterwards, the phosphide would not have time to crystallise. In this case, phosphorus would favour the separation of carbide and diminish the hardening capacity of the iron, because carbide separates simultaneously with phosphide, and, like salt crystals in supersaturated solutions, these secretions favour the further separation of the carbide (mother-liquor).—W. G. M.

**Waste Products in Iron Manufacture.** Eng. and Mining J., June 5, 1897, 566.

AMERICANS are accustomed to claim for their iron and steel plants superiority over those of European countries in many points. In their blast furnaces they claim to have increased the capacity to a point far beyond anything known abroad, and they have been able to make iron at a low labour cost, in spite of higher average rates of wages. This has been secured largely by the use of machinery wherever possible, and by cutting down the amount of labour required to the lowest possible point. To a certain extent also, economy has been secured in fuel and materials; and all this without in the least reducing the standard of quality in the product.

In some respects, however, they have much to learn yet from their competitors. It is, perhaps, a consequence of having abundant supplies of raw materials that they have been careless about their use, and indeed rather inclined to wastefulness. This is especially apparent in the iron manufacture, where they have, as a rule, entirely neglected the by-products which, in other countries, form so important an element, that a German writer has suggested the possibility that before long the pig-iron made will become a by-product, and the blast furnace will be valued chiefly for its output of chemicals. They are considerably behind the English and very far behind the Germans in this respect, and there is corresponding room for improvement.

The most important element of saving in European practice is found in the use of the by-product coke oven, which is almost universal in Germany, and is gradually making its way in England. In Scotland, where the majority of the furnaces use raw coal, and not coke, for fuel, plants are found at a number of the iron works where the gases escaping from the furnace are treated for the purpose of saving the ammonia sulphate, tar, and other chemical products, while the purified gas is used for fuel in boilers. These plants, of course, serve the same purpose as the by-product oven, and are, perhaps, not especially to be recommended except under the peculiar conditions presented in Scotland.

In Germany the slag from the furnaces is used for making bricks, for roads and similar purposes, and new applications for this material are constantly being found. In America such uses are still comparatively rare.

One of the latest applications of a by-product is found at the Cockerill Works at Seraing, in Belgium, where the waste gas from a blast furnace has been for a year past used experimentally to run a gas engine. This has proved so successful—though coke is used for fuel in the furnace—that the company is now putting up two more gas engines of 150 horse-power each, and anticipates in time supplying a large part of its motive power from this source. Blast-furnace gas has also been recently utilised in the same way in Great Britain by Mr. James Riley, the well-known iron-master. Every great iron and steel works should investigate possible uses for what are now their waste products, and, through the applications of science to industry, turn them into profits. The careful saving of by-products will soon be a necessity if iron-men are to hold their own and to build up the foreign trade which is within their reach.

## PATENTS.

**Blast Furnaces, Impts. in.** W. Gibbings, Widnes. Eng. Pat. 7436, April 8, 1897.

To keep the fuel away from the sides of the furnace and to confine the melting zone to the centre thereof (thereby rendering the furnace more durable), the fuel is fed from a receptacle supported on the top of the furnace at the centre. Such receptacle may form part of the flue of the furnace or be independent thereof.—R. S.

**Sulphide Ores of Lead, Impts. in the Treatment of, Preparatory to Smelting the same, and Incidentally to obtaining Sulphurous Acid.** T. Huntington and F. Heberlein, Pertusola, near Spezzia, Italy. Eng. Pat. 8064, April 16, 1896.

As intimate mixture of galena and lime (or other alkali earth) is heated to 700° C., and the temperature is allowed slowly to fall to about 500°, when the mixture is removed to a receptacle through which a current of air is passed. Much heat is generated, and the sulphurous acid given off is collected. This mixture fuses and is then ready for reduction of the metal in a suitable furnace. The reactions assumed to take place consist in the oxidation at the higher temperature of lime into calcium dioxide, which at the lower temperature reacts on the lead sulphide to reproduce lime, and lead sulphate. When the heated mixture, now containing lead sulphate with lead sulphide, is subjected to the action of air, they react to form lead oxide and sulphur dioxide, as shown in the equation,  $\text{PbS} + \text{PbSO}_4 + \text{O}_2 = 2\text{PbO} + 2\text{SO}_2$ .—E. S.

*Manganese-Steel Castings, An Improved Method of Toughening.* R. A. Hadfield, Sheffield. Eng. Pat. 11,833, May 30, 1896.

IN toughening manganese-steel castings by water-quenching, there has always been a liability to the production, during the heating, of internal ruptures which might escape subsequent detection. This difficulty is overcome by heating the castings very slowly, placing them, after cleansing from sand, in a cold furnace, and then raising the temperature so slowly that thick castings ( $1\frac{1}{2}$ —2 ins. in thickness) shall have attained a temperature of  $400^{\circ}$  F. only after 1 hour,  $800^{\circ}$  F. after 2, and  $1,200^{\circ}$  F. after 3 hours' heating. The temperature may then be raised more rapidly to  $1,700^{\circ}$  F.—an orange heat—when they are removed quickly from the furnace and at once plunged into water.—W. G. M.

*Iron and Steel, Carbonising; Impts. in.* A. Wilson and F. Stubbs, both of Sheffield. Eng. Pat. 12,782, June 10, 1896.

THE plate to be treated is covered with a layer of calcium (or other similar) carbide, when resting horizontally in a muffle; a second plate is then placed over this, and a current is passed through the carbide by connecting the plates with the poles of a dynamo, as soon as they have attained a red heat. For plates to be deeply carburised a layer of carbide 3 or 4 ins. thick should be used, and the voltage of the dynamo must be sufficient to overcome the resistance of the carbide when hot, but not necessarily when cold. The greater the quantity of the current, the quicker the result. The plant described allows for 100 amperes at 90 volts being applied to thick plates for 3 or 4 days.

—W. G. M.

*Ores, Pyritic; Improved Process for Extracting Metals from, by Treatment with Chlorine, and for Recovering the Chlorine employed.* O. Frölich, Steglitz, Berlin. Eng. Pat. 13,371, June 17, 1896.

CRUSHED sulphide ores, unroasted, are treated at the ordinary temperature with chlorine, either in the dry state or after being slightly moistened with suitable liquids. Soluble chlorides are then leached out, and the metals and chlorine are recovered by electrolysis, the halogen being used for the treatment of a fresh batch of ore. Thus zinc blende is treated with dry chlorine until no more of the gas is absorbed. The zinc chloride is then extracted with a moderate quantity of water containing a little hydrochloric acid or sodium chloride to hasten the solution of the zinc. When galena and silver are present, both lead and silver remain in the insoluble residue, when they may be extracted afterwards. In the case of auriferous antimony sulphide, the chlorine is first applied dry; the ore is then washed twice with water, dried, and re-chlorinated. The residue is next treated with hydrochloric acid to give antimonious chloride, and the washings are treated for the recovery of gold. Or the crushed ore is moistened and chlorinated, and is treated with dilute tartaric acid solution, which dissolves the antimony, but no gold. The residue is then moistened, re-chlorinated, and treated with water or dilute hydrochloric acid in order to obtain the gold in solution. Pyritic ores containing precious metals is moistened with hydrochloric acid, and is then chlorinated, and the product is treated with hydrochloric acid, giving a solution which contains almost all the gold and silver together with the common metals.—W. G. M.

*Precious Metals, Impts. in or relating to the Precipitation of, from their Cyanide Solutions.* M. B. Zenger, London. Eng. Pat. 12,255, June 4, 1896.

ALKALI-metal amalgam, in the form of spray or of fine stream, is passed through the cyanide solutions containing the gold and silver in a vertical chamber so arranged that the mercury collecting at the bottom is carried up into an elevated tank, where it is again charged with alkali-metal and allowed to flow through the chamber. The cyanide liquor enters the chamber at the bottom from one tank, and, after the removal of gold and silver by the alkali-metal, overflows above into another.—W. G. M.

*Alloys [Bronze], Impts. in.* J. C. Bull, Erith. Eng. Pat. 12,328, June 5, 1896.

THE purest copper obtainable (preferably the best brands of electro-deposited metal) is alloyed with from 2 to 5 per cent. of pure tin, with or without (at most) 0.1 per cent. of phosphorus or 0.2 per cent. of manganese added at the end for the purpose of deoxidation; and the fused mixture is run into ingots, which may then be worked at a red heat into bars, sheet, tubes, or wire.—W. G. M.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A.)—ELECTRO-CHEMISTRY.

*Standard Cell, The Cadmium.* W. Jaeger and R. Wachsmuth. *Ann. der Phys. und Chem.* 1896, **59**, 575; *Proc. Inst. Civil Eng.*, 1897, **127**, [1], 73—74.

THE authors recommend a cell similar to the H-form of Latimer-Clark cell with platinum electrodes sealed into the glass. In one limb is placed cadmium amalgam (1 of Cd to 6 of Hg) covered with crystals of cadmium sulphate, and in the other, pure mercury beneath a layer of mercurous sulphate, the tube being filled with saturated solution of cadmium sulphate and sealed with paraffin and cork, with shellac over all. The electro-motive force of the cell at  $20^{\circ}$  C. is 1.019 volt, and its temperature co-efficient is about one-twentieth of that of the Latimer-Clark cell. The following formula is given:—

$$E_t = E_{20} - 3.8 \times 10^{-5} \times (t - 20) - 0.065 \times 10^{-5} \times (t - 20)^2,$$

where  $E_{20} = 1.019$  volt. This formula holds good between  $5^{\circ}$  C. and  $25^{\circ}$  C., but between  $0^{\circ}$  C. and  $5^{\circ}$  C., some cells were found to have an electro-motive force about 0.001 volt higher than the calculated value. The cadmium cell quickly recovers its normal electro-motive force after being heated or cooled through 16 or 17 degrees. The addition of 2 per cent. of zinc to the cadmium amalgam only raised the electro-motive force about  $39 \times 10^{-5}$  volt. An amalgam containing 1 per cent. more cadmium than usual had an electro-motive force about 0.001 volt too high. To ensure absence of free acid, the cadmium sulphate should be digested with cadmium hydroxide, filtered, warmed with mercurous sulphate and again filtered; and the mercurous sulphate should be washed with distilled water till it begins to turn yellow from the formation of basic sulphate.

The maximum variation from the normal electro-motive force of a number of cells which have been under observation since July 1894, was  $8 \times 10^{-5}$  volt.—A. S.

### PATENTS.

*Electrical Accumulators [Plates of compressed Spirals of Lead or Alloy], Impts. in.* F. W. Greengrass, Epsom, and S. R. Docking, Croydon. Eng. Pat. 13,644, June 20, 1896.

THE claims relate (1) to the manufacture of plates composed of entangled spirals of lead or lead alloy gently compressed and having the margins consolidated by melting or burning so as to form a solid edging all round the plate; (2) supporting the negative plates in the cell on lead feet buried upon their bottom corners and suspending the positive plates on tubular rods supported by lugs within the vessel; and (3) methods of sealing the cell by a plate.

—J. C. R.

*Electrolytic Anodes, Impts. in or connected with the Arrangement and Attachments of.* [Carbon.] P. E. Secrétan, Paris, France. Eng. Pat. 14,584, July 1, 1896.

THE surface of the anodes is increased by providing them with ridges or wings, and to provide better connection between the carbon anodes and the metallic conductors, the irregular upper ends of the former are turned and provided with a thread which screws into a metallic socket preferably made of aluminium bronze, and this socket also screws on to the end of the red copper conducting rod. Discs of red copper are placed against the connecting bar at each end of the

part of the socket into which the bar is screwed, or the carbon anode may be held by a grip consisting of several rigid or elastic parts completely insulated from each other, or simply separated by a partial longitudinal slot. This grip is compressed into the anode by means of a nut acting directly on these parts or by the intermediary of elastic jaws, or of a tightening ring, absolute contact being obtained by metal washers interposed between the carbon and these parts.—G. H. R.

*Electrolysis, Impts. in.* G. Poore, London. Eng. Pat. 16,852, July 29, 1896.

In this process for producing electrotypes, electro-plating, decomposing metallic salts, and so forth, the cathode which is unsubmerged, is placed within a tank on a movable table, and the electrolyte is played on it in a jet from a suitably shaped nozzle, which may or may not be constructed of the metal to be deposited. The jet constitutes the only electrolytic connection between the anode and the unsubmerged cathode, and the electrolyte falling off, the latter passes through a tray containing the salt of which it is composed, so as to maintain its strength, and collects in the lower portion of the tank, from which it is pumped back to the jet. Both the anode and the cathode may be moved relatively to one another.—G. H. R.

[*Alkaline Percarbonates.*] *Chemical Products, Manufacture or Production of, by Electrolysis.* E. J. Constan and A. von Hausen, Zürich. Eng. Pat. 19,218, Aug. 31, 1896.

See under VII., page 537.

*Electrical Furnaces [Carbides, &c., under Vacuum or Pressure], Impts. in or relating to.* A. J. Boulton, London. From O. Patin, Paris. Eng. Pat. 19,290, Sept. 1, 1896.

See under II., page 528.

*Electric Furnaces [Arc moved by Magnets], Impts. in or connected with.* F. J. Patton, New York, U.S.A. Eng. Pat. 4138, Feb. 16, 1897.

See under II., page 528.

*Storage Battery [Peroxide on Plate of Pumice], An Improved.* J. Entwistle, Manchester. From C. T. Barret, New York, U.S.A. Eng. Pat. 6818, March 16, 1897.

The improvements relate to the use of a cell having a porous plate of pumice stone, in and upon which the peroxide is applied, the said porous plate and peroxide being enclosed in a leaden box (faced interiorly with a layer of coke dust) which secures the parts in intimate contact, whilst providing for the admission and circulation of the acidulated solution. The perforated lead support is supported again with perforated insulating material, such as rubber, vulcanite, or their equivalent.—J. C. R.

*Primary Electric Batteries or Generators [Heating the Electrolyte], Impts. in.* S. Van B. Essick, Yonkers, U.S.A. Eng. Pat. 8131, March 30, 1897.

The positive and negative (zinc-copper or zinc-carbon) elements are in contact with a single battery liquid (20 parts of water and 1 each of sulphuric acid and copper sulphate) which is "subjected to heat sufficient for depolarisation." Means are provided for automatically keeping the liquid supply in the generator.—J. C. R.

## (B).—ELECTRO-METALLURGY.

### PATENTS.

*Electrolytic Depositions, An Improved Apparatus for Producing Galvanic or.* [Rotating Drum.] W. P. Thompson. From The Elektro Galvanoplastische Anstalt, H. Feith and A. Floeck, Cologne, Germany. Eng. Pat. 11,730, May 29, 1896.

The rotating drum is lined with sheets of the metal to be precipitated, which are insulated from each other, and are so connected by means of a commutator to the dynamo

that those plates which, for the time being are uppermost, serve as anodes, whilst the lower plates on which the work rests, form the cathodes.—G. H. R.

*Electro-plating Apparatus, Impts. in.* [Electro-plating Workholder.] R. J. Marks, Connecticut, U.S.A. Eng. Pat. 2470, Oct. 12, 1896.

The apparatus is designed to distribute the current evenly to all the work to be plated which it contains, and consists of a tray, formed of an insulated frame, containing a series of permeable, conductive floor sections insulated from one another, and the alternate sections at either end are connected to hangers, by means of which the workholder is suspended from a rod connected with the negative terminal of a dynamo. The workholder may be provided with a permeable cover.—G. H. R.

*Metals, Impts. relating to the Coating or Covering of, and other Substances with, and other Materials by the aid of the Electric Arc.* [Ships' Hulls, &c.] F. H. Snyder, Westcombe Park, England. Eng. Pat. 25,360A, Nov. 11, 1896.

The metallic or other structure is plastered over with a mixture made of a glutinous or binding material and a finely divided metal or alloy which it is desired to use as a coating, and this metal is then fused on by the arc. If a vitreous covering be required, the surface of the body is smeared with a plastic mixture of a suitable silicate, or of powdered glass, and a binding material, with a substance which is a good conductor of electricity, and the coating is fused on as before.—G. H. R.

*Electric Furnaces [for treating Ores], Impts. in.* E. F. Price, Niagara Falls, U.S.A. Eng. Pat. 27,301, Dec. 1, 1896.

The claims are for combinations of parts in furnaces which are described with drawings, and relate principally to the construction of the bottom or hearth [slab of carbon] of the furnace forming one electrode, and "a range of electrodes [carbon] substantially perpendicular to the bottom." Means of feeding the material and for the escape of the gases produced, are also the subjects of claims. The object of the invention is "to decompose the ore or other material, or melt the same under an electric current, and the material decomposed or melted is caused to pass or run off the hearth which is set at an inclination, and it is to be adjusted to greater or less inclination according to the material operated upon, so that the electric treatment can be substantially continuous."—J. C. R.

## XII.—FATS, OILS, AND SOAP.

*Residues from the Distillation of Starchy Substances Treatment of.* [Oil Extracting.] Bull. Soc. d'Encouragement, 96, 1897, 161—165.

THE process elaborated by Donard and Bonlet for extracting the oil from distillers' and brewers' grains, starch-makers' residues, &c. consists in drying the material under a pressure of 40 mm. of mercury and extracting by petroleum spirit (boiling point 60°—100° C.).

The drying apparatus consists of a horizontal revolving cylinder  $2\frac{1}{2} \times 2\frac{1}{2}$  metres containing a number of tubes into which steam is introduced through one of the hollow axes, and exhausted by a double-acting pump *via* the other. The charge (2,500 kilos. of grains, containing 55 per cent. of moisture) is introduced through manholes, and the apparatus being rotated at a speed of three revolutions per minute during  $3\frac{1}{2}$  hours, the moisture is reduced to 15 per cent. (equivalent to the evaporation of 1,000 kilos. of water) with a consumption of 3 cwt. of coal.

The extracting apparatus consists of a pair of vertical boilers  $2\frac{1}{2} \times 2\frac{1}{2}$  metres and two vertical extractors, 120 × 310 cm. with a common condenser, one-half of the apparatus being worked at a time.

The extractor is charged with 2,200 kilos. of dried material and the boiler with 2,800 to 3,000 kilos. of petroleum spirit. Heat being then applied, the latter is volatilised

and ascends to the top of the extractor, where it condenses and passes down through the contents into the other boiler, the operation taking nine hours to complete. The residual spirit is driven out from the mass by the steam from water at the bottom of the boiler, and is passed through the condenser into the second boiler, the contents of the latter being then employed to extract the charge in the second extractor. Not more than 0.43 to 0.75 per cent. of spirit is lost.—C. S.

*Glycerin, The Quantitative Estimation of.* F. Bullheimer. *Forsch.-Ber. u. Lebensm. u. ihre Bez.* 3, Hyg. &c. 4, 12 and 31; *Chem. Centr. Bl.* 1897, 522 and 773.

#### PATENT.

*Cleaning Agent [Saponaceous Mixture], Process of Manufacture of a.* J. C. F. Müller, Hamburg. Eng. Pat. 1554, Jan. 20, 1897.

FIVE kilos. of oleic acid are saponified with  $1\frac{1}{2}$  kilos. of caustic soda,  $1\frac{1}{2}$  of potassium carbonate, and 3 or 4 litres of water. 25 kilos. of Iceland moss are made into a mucilage with the smallest possible amount of water, mixed with 5 kilos. of "linseed mucilage produced by boiling," and 125 kilos. of salicylic acid added as an antiseptic; the whole being finally incorporated into one. The mixture is specially suited for cleaning ceiling-paintings, work done in wax colours, and oil paint generally, as it is "neutral," and does not damage the object; but in the case of articles which have to be freed from old oil colour, it may with advantage be made more strongly alkaline.—F. H. L.

### XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

#### (A.)—PIGMENTS, PAINTS, &c.

*Red Lead, Variations in the Composition of.* D. Woodman. *J. Amer. Chem. Soc.* 1897, 19, 339–341.

IN the manufacture of red and orange lead, colour is primarily of first importance for pigment purposes, whilst the degree of oxidation, apart from its influence on colour, is not esteemed of much importance. For certain purposes, however, the degree of oxidation is important, and the author having occasion to examine a large number of samples from various sources, adopted the method of digestion with a saturated solution of normal lead acetate, by which the litharge in excess of that in combination as  $Pb_2O_3$  (or  $2PbO.PbO_2$ ) is dissolved out. In this way a series of results was obtained, showing a variation from 41 to 92 per cent. of actual red lead.

The interesting point was the large amount of monoxide in some samples which had escaped oxidation, and was separable by the acetate treatment, and which, from the ease with which it was separated, showed that it played no part in the chemical constitution of red lead, but was simply an admixture, and, as such, an indication of the completeness or otherwise of the oxidising process.

The separation of the litharge from the red lead was quite sharp, and prolonged digestion failed to effect any alteration in the weight of the actual red lead.

By the usual methods of analysis depending on the decomposition of the red lead into peroxide which remains insoluble, no distinction is made between the monoxide in combination as  $2PbO.PbO_2$  and that present in excess and extracted by acetate solution, analyses usually being stated in such a form as:—Peroxide,  $PbO_2 = 26.4$  per cent.; litharge,  $PbO = 69.7$  per cent.; impurities, 3.5 per cent. Total = 99.6 per cent. However, it would be more satisfactory for commercial work to state it as, peroxide of lead ( $26.4$  per cent.) equivalent to red lead =  $75.6$  per cent.; lead monoxide =  $20.5$  per cent.; impurities, 3.5 per cent. = 99.6 per cent.—O. H.

#### PATENTS.

*Ferric Oxides [Pigment], Impts. in the Manufacture of.* A. Crossley, Cwmavon, Monmouth, and H. A. Allport, Barnsley. Eng. Pat. 13,244, June 18, 1896.

FERROUS sulphate is mixed with about 1 per cent. of an oxidising agent, such as sodium or potassium nitrate or chlorate, in a wet state, and the mixture is charged into the calcining furnace as a stiff paste. It is stated that the sulphuric acid is liberated by this process at a lower temperature than otherwise, and that the colour of the oxide obtained, is improved. Reference is made to Eng. Pat. 2618, 1894 (this Journal, 1895, 157).—E. S.

*Colours for Water-Colour Painting, A Process for Making.* F. Beindorff, Hanover, Germany. Eng. Pat. 28,950, Dec. 17, 1896.

A PROCESS for making water colours, consisting in adding to the binding medium used, a mixture of "an aqueous solution of dichlorhydrin fat, acid-soda, and a preparation of pigs' gall."—R. B. P.

*Pigments, Printing Inks, or Paint Mixtures; Impts. in and in the Manufacture of.* E. O. S. and H. R. Gentele, Stockholm. Eng. Pat. 7399, March 22, 1897.

"LAKES" are produced by staining wood-pulp, cellulose, &c., either before or after grinding, with the desired dye; the result being that a given amount of colouring matter can be distributed over a larger quantity of base than when alumina and similar substances are employed. The manufacture of printers' inks and paints from pigments made in this manner is also claimed.—F. H. L.

#### (B.)—RESINS, VARNISHES.

*Gum Arabic and Frankincense, some Indian Substitutes for; Report on the Examination of.* Imp. Inst. J. Research Dept. 3, [28], 123.

See under XVI., page 548.

### XIV.—TANNING, LEATHER, GLUE, SIZE.

#### PATENTS.

*Glue Compounds, Impts. in, and in Applying the same to Barrels and the like.* J. Howden, Glasgow. From Julius Tyciak, Olszancza, Galicia. Eng. Pat. 3073, Feb. 5, 1897.

THE improved glue is made by combining ordinary glue, 640 parts; Pecher's natural gum, 210 parts; glycerin, 85 parts; ferrous sulphate, 57 parts; tannic acid, 5 parts; and soda crystals, 3 parts. It is used for coating the interior of barrels for containing light hydrocarbons, rendering them fluid and vapour tight.

"The hot compound is put into a barrel, the bung closed, and the barrel rolled about." The air pressure forces the compound into the pores of the wood.—J. T. W.

*Tanning, Arrangement for Performing a continuous Mode of.* H. Schmidt and J. Landini, Hamburg. Eng. Pat. 13,686, Feb. 12, 1897.

THE tanning is conducted in a series of four drums connected with each other by pipes in such a way that the extract solutions used can be forced from one drum to the other by means of compressed air; the liquor used for finishing the tanning being the strongest, passing back to the next drum, and so diminishing in strength until it can be used on the freshly introduced hides. Heaters are arranged for raising the temperature of the liquor before its entry into the drums. Water can also be supplied whilst the drums are rotating. Illustrations show the arrangement of pipes, &c.—J. T. W.

*Hides or Skins for Transport or Manufacturing Purposes, A Process for Preserving.* J. W. Scott, Albionville, Queensland. Eng. Pat. 8168, March 30, 1897.

THE hides, after washing free from blood, are treated with a mixture of molasses and water instead of salting them. The liquid ferments. With a mixture of 10 per cent. strength, the hides are cured in about seven days; they are then hung up to dry, and may afterwards be folded up and shipped.

None of the insects that attack salted hides touch hides treated by this process. The action is due to a "lactous or butyrous" fermentation.—J. T. W.

## XV.—MANURES, Etc.

*Manure, New versus Old.* Agricult. J. 10, 315; Pharm. J. 1897, [1405], 472.

EXPERIMENTS made in Canada last year showed that 8,000 lb. of manure placed under shelter and weighed once a month was reduced to 2,600 lb. between March and December. The manure was at its best at the end of four months, weighing 3,480 lb. The experiments of eight years appear to show that the action as between fresh and rotted manure is equal, ton for ton. In England, where the soil is stiff, fresh manure would, perhaps, be more beneficial, as the soil is lightened by its use; but in Canada, taking into consideration the undigested seeds in fresh manure, the small rainfall, and the outlay in the daily carting of the manure, it would certainly not be economical.—A. S.

*Sulphate of Ammonia from Blast Furnaces, Agricultural Value of.* F. J. R. Carulla. J. Iron and Steel Inst., May 1897.

THE object of the paper is to call attention to the manurial value of sulphate of ammonia, which the author considers is neglected, not on account of any inherent deficiency, but owing to the persistency with which nitrate of soda is pushed to the front. Results of Wagner's experiments with grass, rye, and buckwheat are quoted, showing the equal manurial value of  $\frac{3}{4}$  cwt. of sulphate of ammonia and 1 cwt. of nitrate of soda. (See this Journal, 1897, 110, and 1896, 863.)—N. H. J. M.

## PATENTS.

*Superphosphates and the like, Impts. in the Manufacture and Storing of.* F. M. Mooney and A. Dickson, Dublin. Eng. Pat. 9789, May 8, 1896.

PHOSPHATIC materials are mixed with acid to form "superphosphate" at such an elevation as to admit of running the compost while it is yet fluid into large stores, used as "dens," where it may be kept for a considerable time, till the reaction is completed and the heat fully utilised in evaporating moisture. Instead of elevating the mixer, it may be made portable; or horizontal or slightly inclined conveyors may be employed to carry the material from the mixer to the stores.—E. S.

*Phosphates and other Substances, Impts. in Dissolving and Drying.* J. Milne, Ioverurie, N.B. Eng. Pat. 12,765, June 10, 1896.

PHOSPHATES mixed with acid are discharged from the mixer through a hopper on to the uppermost of a series of double

rows of plates, fixed to traction chains, arranged as an endless apron and moved by slow driving gear, within a closed chamber through which hot air or gases of combustion from a furnace are caused to pass, cold air being also admitted so as to avoid overheating the manure. The material, as it is discharged from the upper row of plates, is carried successively upon a series of other superposed rows, until it falls into a screw conveyor or other means of discharge. It is stated that the mixture of phosphate and acid charged into the apparatus, is mechanically and chemically changed during its passage through the same, from a semi-liquid material to a dry powder; or from tribasic phosphate of lime and sulphuric acid to monobasic phosphate of lime and calcium sulphate.—E. S.

*Moss-Litter Manure, Treatment of, for Obtaining Products therefrom.* E. van de Griendt, Rotterdam, Holland. Eng. Pat. 17,883, Aug. 12, 1896.

Moss litter that has been used for stable purposes is treated with steam in a boiler while being agitated. The steam passing from the vessel "is allowed to percolate through sulphuric acid" to obtain ammonium sulphate. The liquid portion in the boiler is run off and evaporated to obtain "a mixture of nitrates, phosphoric acid, and alkali" for use as a manure. The residual mass is dried for application as a fuel.—E. S.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Starch Manufacture, Organisms in.* Dr. Saare. Zeits. für Spiritusind. 1897, Supplement 11., 4—7.

IN the Halle or acid process for making wheat starch, organisms set up fermentation of the steeped and bruised wheat and thus dissolve the albuminoid integument of the starch granules. This process is, however, being gradually abandoned in favour of others, in which the gluten is recovered in the residuals. In the production of cereal starches, sulphurous acid or alkali is used, and suppresses organisms; though in drying, mould or fermentation may develop and cause discolouring of the product. Organisms abound in the manufacture of potato starch, many being derived from diseased potatoes. *Phytophthora infestans*, the fungus of potato disease, spreads through the tuber, and makes the starch granules either dissolve or assume a more or less acicular form, so that they settle badly; or particles from the rind pass the sieves and discolour the starch. Seab and dry rot are due to organisms, and cause specks in the starch. Wet rot is a more formidable disease, and gives rise to bacteria which cause putrefactive fermentation of the liquor and loss of starch. The starch will also be affected if the water used in its production contain algae, diatoms, decaying vegetable matter, or certain bacteria, especially those common in chalybeate waters.

If the temperature of the factory do not exceed 10° C., bacteria do not occur in large numbers in the liquors, but if the sieves be not frequently cleansed, a mould forms on and chokes them, and a loss of starch results. With proper cleansing and sound potatoes, few bacteria or germs will be found in the starch milk at that temperature; but if, on the other hand, the washing take place at 20–26° C., bacteria will multiply and the liquors will become acid. The starch produced therefrom will retain traces of acid and a rank acetous smell, whilst its colour will be injured through albuminoid particles and fungoid growths which will pervade it. It was found by experiment that an addition of 12 litres of sulphurous acid ( $2\frac{1}{2}$  B.) to a tank of 4.5 cb. m. capacity almost wholly suppressed the bacterial fermentation at these higher temperatures and diminished the amount of scum formed. It did not, however, entirely destroy the sporules from diseased potatoes. When fermentation has been permitted, the dried scum is brown, but when it has been suppressed by sulphurous acid the scum is yellow. Fermentation prevents rapid and complete settling of the starch. The manufacture should be pursued as much as possible in the winter; at warmer times, or when diseased potatoes are treated, an addition of sulphurous acid increasing with the temperature should be made. Rapid drying at a comparatively high temperature is less favourable to the spread

of bacteria than prolonged drying. The complete aeration by centrifugal drying machines greatly checks the bacteria. The presence of bacteria is of no moment in many of the applications of starch, but it is important in the case of the starch used in the production of pressed yeast, as the bacteria may set up a putrefactive fermentation which is very injurious.

The presence of bacteria in the waste pulp is beneficial, as, after removal of water, lactic acid fermentation sets up, and improves the value of the waste as fodder for cattle. The milk of the cattle fed thereon is improved both in quality and quantity. The effluent liquors, if applied to land, are also benefited by the presence of bacteria, which convert the nitrogenous constituents into forms from which the nitrogen can be assimilated by plants.—J. A. B.

*Starch Transformation [into Soluble Starch and Dextrin] by Sulphur Dioxide.* A. Bergé. Bull. Assoc. Belge des Chimistes, 10, [12], 444–447.

Below 80° C. the action of sulphur dioxide, whether liquid or gaseous, on starch is almost nil, but between that temperature and 115° C. soluble starch is formed. On the other hand, above the last-named temperature, conversion (in the absence of moisture) into a very pure dextrin occurs, though beyond 140° C. the product turns yellow, and the author has prepared dextrin—containing not more than 0.25 per cent. of glucose—on an industrial scale by heating dry potato starch with sulphur dioxide at 140° C. for seven hours in a revolving cylinder.

With sulphurous acid in solution the action is extremely feeble below 45° C., but at 100° C. saccharification to glucose begins, and is complete between 135° and 140° C. The most favourable conditions for this conversion are: Temperature, 135° to 140° C.; pressure, 6 atmospheres; proportions of the mixture, 25 per cent. of starch and 75 per cent. of water containing 3 to 6 per cent. of sulphurous acid. The reaction is complete in about an hour.

In the case of potato starch, the granulose is rapidly converted, but the starch cellulose is attacked much more slowly. The presence of extraneous substances retards the operation.—C. S.

*Gums for Thickening.* C. Gassmann. Färber Zeit. 8, [9], 135–136, and [10], 153–155. (See also this Journal, 1897, 237.)

THE author describes certain insoluble gums derived from Africa, which can be rendered soluble by boiling with water under pressure, and may then be used as thickeners. These solutions are bleached and evaporated to dryness by well-known means, and the gums thus obtained are put on the market in broken flakes about 0.5 to 1.0 cm. thick, as *gommés cristallisées* or *gommés solidifiées*,—which are all soluble.—L. S.

*Gum Arabic and Frankincense, Some Indian Substitutes for; Report on the Examination of.* Imp. Inst. J., Research Dept. 3, [28], 123–124. (See also this Journal, 1892, 403.)

THREE gums and one gum-resin, received from the Conservator of Forests, School Circle, N.W. Provinces and Oudh, were examined.

I. Simla Gum (*Bauhinia retusa*).—The sample consisted of large rounded tears, &c., which broke easily with a vitreous fracture and were brown in colour. The fragments were translucent, and varied in colour from yellow to brown. The gum was odourless, and bland and mucilaginous in taste. It contained 13.5 per cent. of moisture and 3.18 per cent. (on the dried gum) of ash. A 10 per cent. solution, made for determining its viscosity, yielded a mucilage so thick that it could not be manipulated. A 5 per cent. solution was therefore employed. Even with this dilution, a considerable quantity of the gum remained insoluble, and was removed by straining through muslin. The solution was not precipitated by neutral lead acetate, but with basic acetate it formed an opaque white jelly. It was also immediately gelatinised by the addition of ferric chloride. The gum contained no starch and only a trace of dextrin or sugar.

II. Jingan Gum (*Odina Wodier*).—The gum had very little taste, a slight odour, and varied from white to yellowish-white in colour. It contained 12.3 per cent. of moisture and 8.73 per cent. of ash (on the dried gum). It was completely soluble in twice its weight of water, forming a rather thin mucilage of light brown colour, which possessed considerable adhesive power. The solution behaved like that of the *Bauhinia retusa* gum towards neutral and basic lead acetate and ferric chloride. It contained no starch, but had a marked reducing action on Fehling's solution, indicating the presence of dextrin or sugar.

III. Pial Gum (*Buchanania latifolia*).—This consisted of large irregular masses, tears, and small fragments. The tears were fissured and opaque; the fragments were clear and glassy, as also were the larger masses. The latter contained considerable quantities of impurity, pieces of bark, &c., and the whole sample was contaminated with vegetable debris. It had little taste or odour, and the fragments varied in colour from yellow to reddish-brown. It contained 14.2 per cent. of moisture and 6.27 per cent. (on the dried gum) of ash. The gum was not entirely soluble when mixed with twice its weight of water, a portion (about 10 per cent.) swelling up and forming a gelatinous mass which remained undissolved. The mucilage obtained by treating the gum with twice its weight of water was thick, dark in colour, and possessed strong adhesive properties. The solution gave the usual reactions of gum-acacia, behaving with neutral and basic lead acetate and ferric chloride exactly as the two preceding samples. It contained no starch and only a trace of dextrin or sugar.

*Comparative Viscosities.*—The viscosity of the solutions of these gums was compared with that of a solution of the best gum arabic, by noting the time taken by 50 c.c. of the solution to flow from a burette fitted with a fine nozzle.

	Strength.	Burette Time in Seconds.
	Per Cent.	
Gum arabic.....	10	78
<i>Odina Wodier</i> .....	10	58
<i>Buchanania latifolia</i> .....	10	184
<i>Bauhinia retusa</i> .....	5	200

IV. Salhar Gum (*Boswellia serrata*).—The specimen of this gum-resin, which is closely related to ordinary frankincense, consisted of small rounded tears and larger irregular masses. The odour and taste were strongly terebenthinous. The gum-resin readily burned, and on analysis gave the following figures:—Resin, 53.2 per cent.; gum, 36.45 per cent.; volatile oils, 7.0 per cent.; ash, 1.55 per cent. The gum was completely soluble in water, and the solution gave the ordinary reactions of gum-arabic. The greater part of the volatile oil boiled at 157° C., after which the temperature rose to over 170° C.

Analyses of true frankincense have been published by Braconnot (Ann. de Chim. [2], 68, 60), who found—resin, 56 per cent.; soluble gum, 30 per cent.; insoluble gum, 6 per cent.; volatile oil, 8 per cent.; and by Kurbatow (Zeits. für Chem. [2], 7, 201), who found—resin, 72 per cent.; gum, 21 per cent.; volatile oil, 7 per cent.—A. S.

*Alcoholic Fermentation without Yeast Cells.* (II.)

E. Buchner. Ber. 1897, 30, 1110–1113.

IN continuation of his former experiments (this Journal, 1897, 16, 156), the author now gives some new results to disprove the view that the fermentative effects described in

his former paper might be attributed to the action of minute particles of living protoplasm. He finds that the stability of the yeast extract is not affected by the presence or absence of air, and the destruction of its activity is probably due to the presence of peptic enzymes. The loss of activity is thus accompanied by a diminution of the coagulable albumin. This hypothesis also explains the preservative action of a concentrated solution of cane-sugar, which it is thought would destroy the activity of the peptic enzyme. The addition of antiseptics, such as chloroform, benzene, and sodium arsenite, does not destroy the fermentative activity of the yeast extract, and as these substances hinder the growth of living yeast cells, they would be expected to act much more injuriously upon suspended particles of plasma deprived of their protective membrane. It is further found that the yeast extract may be evaporated to dryness without loss of activity; this may be effected in about 6 hours by exposing it in thin layers to a temperature of 30°–35° and under a pressure of a few millimetres. The dry product may be redissolved in water, and the solution, after filtration, gives a bright filtrate, which, when mixed with a 75 per cent. solution of cane sugar, will produce a distinct fermentation in 6–10 hours, and the evolution of gas will continue for days. The dried residue retains its activity certainly for 20 days, and probably much longer. The author has also succeeded, after several unsuccessful attempts, in isolating an active substance by precipitation with alcohol. In further proof of the existence of zymase, it is stated that when well washed and dried (at 37°) yeast was heated for 6 hours at 100° so as to kill all the yeast cells, the product still gave rise to a vigorous fermentation when added to sterilised cane-sugar solution. When, however, the yeast was heated for 1 hour to 140°–145° the zymase was destroyed and its fermentative power was lost.

—A. K. M.

*Diastase, Action of Light on, and its Biological Significance.* J. R. Green. Proc. Royal Soc. 1897, **61**, 25–28.

ACCORDING to the observations of Brown and Morris (J. Chem. Soc. 1893, **63**, 604), the quantity of diastase in foliage leaves undergoes considerable variations during the 24 hours of the day, being greatest in the early morning and least in the evening, particularly after several hours' sunshine. During the past three years the author has conducted a series of experiments to ascertain whether the diminution in quantity is due to a destructive influence of the light upon the enzyme, similar to that observed with micro-organisms and other low forms of vegetation.

The investigation has been carried out by exposing various solutions containing diastase to the action of light for several hours, either that of the total spectrum or selected portions of it, and after each such exposure testing the hydrolysing power of the solutions upon a weak solution of soluble starch, or upon a 1 per cent. starch paste. Controls were carefully kept during each experiment, so that any difference shown in diastatic power could be only attributed to the illumination. The diastatic solutions consisted of malt extract, solution of diastase precipitated from such extract by alcohol, diluted human saliva freed from mucin, and extracts of foliage leaves. The solutions were preserved by the addition of 0.2 per cent. of potassium cyanide. The sources of illumination were bright sunshine, diffused daylight, or the light from a naked electric arc. The diastatic power has been ascertained by titrating the results of the digestions with Fehling's solution, burning the filters with the precipitates, and weighing the resulting cupric oxide. When all the rays of the spectrum were under investigation, the solutions of diastase were exposed to the light, either in quartz-fronted cells, or mixed with films of agar-agar, the former method giving the most satisfactory results.

From many experiments it was found that exposure to the whole of the spectrum for several hours caused the destruction of from 20 to 60 per cent. of the diastase. When the ultra-violet rays were eliminated by the use of glass vessels there was at first a considerable increase in the diastase, but this was succeeded, on an exposure lasting for

several days, by a gradual and almost complete destruction of the enzyme.

By the use of a series of screens, arranged according to the directions of Landholt (B.-r. 1894, 2892), the spectrum was divided into red, orange, green, blue, and violet. The infra-red, red, orange, and blue regions gave increases of diastatic power of 10.8, 53.5, 4.75, and 20.8 per cent. respectively; the green gave a diminution of 15.7 per cent. The violet also gave a marked diminution. The effects of the illumination were found to be progressive, the increase or diminution of the diastase continuing after the solutions were removed from the access of the several rays. The deleterious rays were found to be absorbed by the solution, this being partly effected by the diastase itself, whether boiled or unboiled, and partly by the proteids present in the extracts. After removal of the latter by boiling and filtration, the solution was still opaque to the rays. The screening influence of proteids was examined separately, by adding small quantities of egg albumin to the extracts. The degree of protection was, however, only roughly proportional to the amount of albumin present. The colouring matter of the barley grain was found to act as a screen to the deleterious rays.

The living leaf was examined by the same method as the extracts, and the diastase in it was found to undergo a similar destruction under the influence of the light. It was found impossible to investigate the possible protective influence of chlorophyll in the leaf, as all the solvents of the latter were found to be opaque to the ultra-violet rays. They confirmed the view that the violet rays, and possibly the green, have a destructive effect upon the enzyme.

The author concludes from his experiments that there exists in the leaf, and in the various extracts examined, a certain amount of zymogen which is converted by the infra-red and the red, orange, and blue rays into active diastase. This conclusion is supported by experiments upon the effect of keeping the solutions for several days at a temperature of 38° C. The violet and ultra-violet rays, on the other hand, cause a destruction of the diastase, or at least such a change in the configuration of its molecule that it is unable to effect the hydrolysis of starch. The following three conclusions have also resulted from this investigation:—1. That the enzyme is not located in the chlorophyll grain, but in the protoplasm of the cell. 2. That the suggestion of Pick (Bot. Central. **16**, 9–12) and Johow (Pringsheims Jahrb. **15**, 299), that the red colouring of certain leaves is a material help to the translocation of starch in them is probably sound, as such colouring matters screen off the rays which destroy the diastase. 3. That there exists in plants a power of absorbing and utilising the radiant energy of light, sometimes to a considerable extent, without the presence of a chlorophyll apparatus. The last conclusion is of far-reaching importance, supplementing other observations already published by Engelmann (Bot. Zeit. 1888), Winogradski (Ann. de l'Institut Pasteur, 1890–91), Speschnew, and other observers, none of whom, however, have indicated such utilisation of the rays of the visible spectrum.—J. L. B.

*Barley [Malting]. Influence of Drying, on Germination.* Behrend. Zeits. f. d. ges. Brauwesen, **20**, [16], 218.

SAMPLES of wet barley were dried by storage for five weeks, and the percentage of moisture was then found to have receded from 20.88 (maximum) to 12.13 per cent. Concurrently the percentage of germinating corns rose from 67.8 to 91.2 per cent.—counted on the third day—and from 79.7 to 94.8 per cent. on the tenth day after steeping.—an increase in germinating power of the dried over the undried grain of 23.4 and 15.1 per cent. respectively.

The inference drawn from these results is that in the case of wet barley, growers can improve the quality for malting purposes, by storing the grain on airy floors.—C. S.

*Beer, Mexican.* A. Lang. Zeits. f. d. ges. Brauwesen, **20**, [13], 179.

A SAMPLE of beer (from the Oaxaca brewery) prepared from Bavarian malt (from Moravian barley) and Spalt and Saaz hops gave on analysis: saccharometer indication, 3.49° Balling; alcohol, 4.01; extract, 5.25; maltose,

1.114; total acid (lactic acid), 0.124; protein ( $N \times 6.25$ ), 0.5; ash, 0.203;  $P_2O_5$ , 0.089; glycerol, 0.151; and  $CO_2$ , 0.235 per cent. The original gravity was calculated as 12.98° Balling, the apparent attenuation being 73.11, and the actual 59.55.

The beer was pale in colour and apparently modelled on the Bavarian lager type, but of much lower original gravity.

A considerable deposit and characteristic flavour, due to pasteurisation, were apparent.—C. S.

#### Analysis of English, Munich, and Vienna Beers.

*Grape Juice, Wines, Spirits, and the like; Impts. in Means for Treating and Improving.* P. W. May, Child's Hill, and B. E. R. Newlands, London. Eng. Pat. 16,747, July 28, 1896.

THE substance to be treated is heated in a closed vessel to a temperature sufficient to effect sterilisation. The temperature employed may vary, but 71° is generally sufficient. The heat is applied gradually and maintained for a sufficient time, usually about four hours, after which time the product is allowed to cool gradually, the vessel being kept closed during the whole operation.—A. K. M.

*Crude Alcohol and other Alcoholic Mixtures, Process and Apparatus for Purifying.* C. Killing, Düsseldorf. Eng. Pat. 28,713, Dec. 15, 1896.

THE apparatus described, is an upright vessel of cylindrical or other shape, containing a steam coil, at the lower end a stirrer, and is also provided with two adjustable openings at or near the top. For the purification of crude alcohol, the mixture is heated to about 37° to 50°, when mixed vapours will be given off; the alcohol vapour will, however, gradually condense as it reaches the higher portions of the apparatus, and practically pure aldehyde can be led away through one of the openings at the top, air being admitted by the other.—A. K. M.

*Amylaceous Substances, The Economic Treatment of the By-Products of Distillation of.* Report by M. de Luynes, Bull. Soc. d'Encouragement, 1897, 166.

MM. DONARD and Boulet, at their works situated at Bapaume-les-Rouen have treated during the last seven

years about 13,000,000 kilos. of maize cake from which 3,500,000 kilos. of oil were extracted. Incidentally they have also produced in one year 20,000 kilos. of wheat oil, 7,000 kilos. of rye oil, and more than 200,000 kilos. of rice oil. They avoid the resinification of the oil, and obtain complete extraction from the cake, by—

1. Drying at a low temperature under a pressure of 10 mm. in a rotatory apparatus.
2. Extracting the oil with boiling petroleum spirit.

—V. C.

*Gingers, Commercial, and Essence of Ginger.* W. S. Glass. Pharm. J. 1897, 54, 245.

Of the three commercial varieties of ginger, Jamaica, Cochin, and African, the last is found to be richest in oleo-resin, yielding 6.3 per cent. compared with 5.0 per cent. from the Jamaica variety, and 4.6 from Cochin ginger. African ginger is therefore recommended for the preparation of the soluble essence of ginger, which may be obtained by adding to 8 fluid parts of ordinary essence, 3 parts of powdered pumice, shaking occasionally for 12 hours, then adding gradually 21 parts of distilled water, shaking after each addition, allowing to stand for six hours and filtering.

## PATENTS.

*Preservation of Foods and other Perishable Goods, Impts. in or relating to.* H. Higgins, Cambridge. Eng. Pat. 8232, April 18, 1896.

THE object of the invention is to hermetically seal vessels containing perishable substances, which have been sterilised, without admitting unsterilised air. The vessel is fitted with a cork, which is pushed down to below the upper edge of the neck. A funnel, containing cotton wool, with a tube of fine calibre which is drawn out to a solid point, but which is perforated just above the point, is now pushed through the cork. The cork is covered with melted paraffin wax or any suitable material which melts at the temperature employed in sterilising. When the vessel has cooled, a hot fluid substance is poured into the space above the cork, so that, as the funnel tube is withdrawn, the liquid flows into the hole, thereby at once sealing the opening without unsterilised air having had access.

A suitable cement can be made of india-rubber or gutta-percha (2 parts), paraffin wax (6 parts), resin (1 part), and magnesium silicate (2 parts). Fusible metal may also be employed.

Other modifications of the sealing process are described.

—N. H. J. M.

*Smoking Salmon and Similar Fish, An Improved Process for, and Means therefor.* C. Waldenmann, Coslin, Germany. Eng. Pat. 12,904, June 11, 1896.

THE fish is prepared and cut in the usual manner, and the exposed portions evenly covered with animal bladder, vellum, or other suitable material. The pieces of fish are then placed on stands, formed of triangular plates and an overcoating of wire gauze, and exposed to the smoke of a wood fire. The advantages claimed for the process are the prevention of flaws and cracks in the inner side of the fish, which are apt to become mildewed, and the shortening of the smoking process, owing to the fish drying more rapidly when kept in a horizontal position than when hung in the ordinary manner.—N. H. J. M.

*Drying Fruit and the like, by Air and Furnace Gases, Impts. in Apparatus for.* O. Schmeisser, Landsberg-on-the-Warthe, Germany. Eng. Pat. 28,414, Dec. 11, 1896.

A process of fruit drying is described such that, in the case of stone fruit from which the stones have not been separated, the heat is so applied that whilst the fruit itself is dried, the stones also become dry. The stones have, as a rule, to be heated below 100° C., whilst the flesh of the fruit may, at first, be exposed to a higher temperature. The material is fed in a long continuous stream in the same direction as the hot gases from a fuel furnace. The drying gases pass into different compartments, to prevent their being mixed, so arranged that the fresh fruit receives the greatest heat, and that the heat becomes less as the fruit approaches dryness. In order that the fruit may be uniformly heated during its passage, it is mixed by means of a rotating perforated drum. Small fruit, which dries more quickly than larger fruit, and would, therefore, be liable to become overheated, passes through holes arranged at convenient distances in the drum, into suitable receptacles.—N. H. J. M.

## (B.)—SANITATION; WATER PURIFICATION.

*Aluminium Bronze Colours, Danger of Explosion and Fire in the Manufacture and Storage of.* R. Kayser. Zeits. öffentl. Chem. 3, 93—94. Chem. Centr.-Bl. 1897, [1], 833.

THE author observed repeatedly that the aluminium bronze colours became oxidised in the settling vessels, to aluminium hydrate, with evolution of hydrogen. This decomposition by water only took place if the temperature of the rooms in which were the settling vessels rose above 25° C. The evolution of hydrogen begins slowly, but in consequence of the heat of the reaction becomes very vigorous. As there may be present in a settling vessel 6 kilos. or more of the bronze colour, capable of evolving at least 7 cb. m. of hydrogen, there is the possibility of a dangerous explosion, by the formation of considerable quantities of inflammable gas in the rooms. By admission of moisture and heat to packed aluminium bronze, evolution of hydrogen may take place, and if the packing material be inflammable, may lead to fire. Spontaneous combustion of bronze colours was also caused by strong blows or friction, due probably to small quantities of adhering fat or benzene. These phenomena were not observed with bronze colours made from copper-zinc and copper-tin alloys.—A. S.

*Waste Water from Print Works, The Purification of.* R. J. Flintoff. J. Soc. Dyers and Colourists, 1897, 99—104.

THIS paper contains a criticism of the circular of the Mersey and Irwell Joint Committee, a general discussion of the purification of a print work's effluent, and a description of a plant and process for the purpose.

The waste waters first enter a deep "sludge tank," where a partial subsidence of suspended matter, as well as of any precipitates formed by the mixing of different waste liquors, takes place. Here also fatty matters separate and collect on the surface as a thick scum, which is prevented passing into the next tank, as it would soon choke up the filters. The partially clarified water is run into one of the precipitating tanks, is well mixed, and, if acid, is made alkaline by adding some lime. As a precipitant, the author favours a

basic ferric sulphate containing from 5—10 per cent. of aluminium sulphate. A solution of this precipitate is added to the now alkaline water, and the precipitate is allowed to settle for 16—36 hours. The water finally passes through filters composed of cinders, gravel, and sand.

—I. S.

*Filtration, An Improved Method of.* U. S. Consular Repts. 1896, 53, [197], 164—167.

THE following process, devised by Fischer, is used for filtering Rhine water at Worms. Clean sharp sand, when mixed in the proper proportions with finely powdered glass, forms a porous mass, which by roasting at a high temperature may be hardened into any desired form. At present, plates are made 40 ins. square and 8 ins. thick, with a hollow space of 2 ins. in the centre. These plates are placed upright in batteries, and are covered to a depth of 3 or 4 ft. with the water to be filtered. The water is forced by its own pressure through the porous walls of the plate into the internal hollow space, where it trickles down and is drawn off through pipes laid at the bottom of the tank to the reservoir. The discharge pipes are fitted with cocks, so that each plate and group of plates may be isolated for cleaning purposes whilst the adjacent batteries are in operation. For greater economy of space and tubing two tiers of plates may be set one above the other, one discharge pipe serving for both. The plates can be easily and quickly cleaned by reversing the current of water, whereby it percolates outwards through the porous walls and discharges the dirt which has collected on the outer surface. The mud is drawn off and the operation finished by flushing with a jet of water. The head of water necessary to make the filter act with sufficient rapidity, is from 3 to 4 ft., and the reverse head for cleaning should be about 6 ft. The water delivered by the above-described filter is said to be thoroughly purified and suitable for drinking, as well as for culinary and manufacturing purposes.—J. L. B.

### PATENTS.

*Softening Water for Industrial and other Purposes, An Improved Method of and Apparatus for.* E. D'Huart and M. and G. Glaesener, Luxembourg. Eng. Pat. 9646. May 6, 1896.

THIS process depends on the insolubility in water of the oleates of the alkaline earths and the heavy metals, and the ease and rapidity with which the precipitates rise to the surface. The water is agitated with the necessary amount of oleic acid, and sufficient caustic soda to throw down the lime, &c. is added; care being taken to avoid excess. Or sodium oleate may be prepared in a separate vessel from the carbonate, by the aid of steam, and then introduced into the water. For many industrial purposes the opalescence of the softened liquid has no deleterious effect; but it may be clarified, after determination of its alkalinity, by treatment with the equivalent quantity of aluminium or iron salts, or by hydrochloric or sulphuric acid. The latter reaction must also be accompanied by agitation, and it may appropriately take place in the presence of "frictional agents, such as sawdust and paper material"; the water being finally passed through a sand filter.

The specification includes a description of, and a claim for, a suitable plant for dealing with comparatively large volumes of liquid in a short time.—F. H. L.

*Extracting Grease and other Impurities from Feed Water for Steam Boilers and other Purposes, Impts. in Filters for.* E. C. Mills, Manchester, and J. G. Chamberlain, Tipton. Eng. Pat. 11,136, May 22, 1896.

IS THE a cylindrical vessel a perforated D-shaped metal plate is fixed eccentrically, so as to leave an "annular" space between it and the casing on one side, and a small space on the other. It is bolted to the walls at its corners, also making a tight joint with the top of the vessel when this is in place, and with the bottom, except in its straight portion, opposite which is the inlet for water. The plate is covered with layers of wire gauze or netting and canvas or asbestos, whilst the inner cavity is filled with wood shavings or the like. The outlet is in the annular space. Suspended

from the cover by bolts is an inverted wooden cone, which can be driven downwards to compress the filtering material. The apparatus is provided with an inlet for steam and a blow-off cock, so that the whole may be cleared from deposit in a direction opposite to the normal flow.

—F. H. L.

*Town and other Refuse, An Improved Method of and Process for Utilising.* L. Cséry, jun., Budapest. Eng. Pat. 29,607, Dec. 23, 1896.

THE process consists in separating and sorting, by suitable mechanical means, the different constituents of the refuse, and utilising each according to its properties. Thus, the comparatively light and combustible bodies, such as paper, wood, straw, and the like, are separated and used as fuel for working the machinery; the manure substances proper, (e.g., ashes, earthy matter, &c.) are separated from fragments of metal, glass, and clay, the latter being likewise sorted; and finally the substances remaining unsorted (principally organic matter) are subjected to dry distillation, the volatile products being collected, whilst the residue from the distillation is added to the manure products.—A. K. M.

*Water (Drinking) Free from Germs, An Improved Process for Rendering.* P. Altmann, Pankow, Germany. Eng. Pat. 5793, March 4, 1897.

A MEASURED quantity of bromine is added to the water, for the purpose of destroying the germs present, and the bromine is then rendered innocuous by the addition of ammonia. The bromine is preferably employed in the form of a potassium bromide solution containing 20 per cent. of bromine, 0.2 c.c. of this solution being sufficient to sterilise a litre of river water in five minutes. For the subsequent removal of the bromine, an equal volume of 9 per cent. ammonia is added. If the water to be treated is strongly ammoniacal, or contains much lime, sufficient bromine must be added until a slight yellow colour is produced and lasts about half a minute.—A. K. M.

### (C).—DISINFECTANTS.

#### PATENT.

*Sterilising Apparatus, Impts. in Steam.* S. Delépine, Manchester. Eng. Pat. 10,934, May 21, 1896.

THE apparatus described is intended for submitting articles of clothing, sheets, blankets, &c. to the action of a current of steam for their thorough disinfection; and it is claimed to be cheap, portable, and simple. It consists of a steaming chamber provided with a valve which blows off at a pressure of 2 lb. The steam is generated in the boiler beneath this chamber, and passes into the latter through an annular opening round the false bottom. The steriliser is jacketed, and water from the boiler is forced in the jacket by the pressure of the steam.

The apparatus may also be used for drying the articles after they have been sterilised. In order to do this, the steam is prevented from entering the inner chamber, but passes through an outer jacket, and escapes through a pipe near the top of the apparatus.—A. K. M.

### XIX.—PAPER, PASTEBOARD, Etc.

*Vulcanised Fibre and other Cellulose Products.* C. Hofmann's Prakt. Handbuch der Papier fabrikation, [44], 1703.

"Vulcanised fibre" is manufactured according to the German Patent, No. 3181 of 1878, by treating cellulose (paper) with zinc chloride solution of 65°—75° B. The gelatinisation of the cellulose is taken advantage of in welding into masses of any required thickness. After removing the zinc chloride, the masses are dried and rendered waterproof by treatment with "nitrating" acid.

*Viscose.*—The sulphocarbonates of cellulose (this Journal, 1893, 516; Eng. Pat. 8700 of 1892) are briefly noticed; also the nitrates of cellulose, as used in the production of celluloid and artificial silk (lustracellulose).—C. F. C.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Bromides and Iodides of Alkalies, Preparation of.*  
J. Kuobloch. Pharm. Zeit. 1897, 42, 190.

THE reactions upon which the process is based consist in first combining the haloids with iron in the form of ferrous-ferric bromide or iodide, which is then decomposed with an excess of milk of lime, the iron being completely precipitated, and a solution of calcium bromide or iodide obtained, which in its turn is decomposed with a solution of an alkaline sulphate. The details of the method may be illustrated by the example of *Potassium Bromide*. Eight parts of iron filings are introduced into a flask with 20 parts of water, to which 16 parts of bromine are gradually added with constant agitation and careful cooling. When action is complete, and the green solution of ferrous bromide is obtained, it is decanted, and another 4 parts of bromine are added to it. The solution is then treated with a slight excess of milk of lime, by which means the whole of the iron is precipitated as magnetic oxide. 21 parts of potassium sulphate are now added, and the mixture is heated on the steam-bath. The hot solution is filtered off, the precipitate washed with hot water, only the first part of the washings being added to the filtrate, the subsequent portions being reserved for a subsequent operation. The small amount of sulphate in the filtrate is then precipitated by the cautious addition of a little barium bromide solution, any slight excess of this salt being decomposed with a very slight excess of potassium carbonate. The solution is then filtered. The filtrate is finally neutralised with a trace of hydrobromic acid, concentrated and crystallised. The bromides and iodides of the other alkalis are prepared in a precisely similar manner, substituting their respective equivalents for the quantities employed in this instance.

—J. O. B.

*Mercurous and Mercuric Salts, The Interconvertibility of.*  
S. Hada. J. Coll. Science. Imp. Univ. Japan, 1897, 9, [2], 161—194.

THE author establishes the following facts:—All mercurous salts dissociate, in presence of water, into mercury and mercuric salts, and reciprocally, all mercuric salts combine with mercury, in presence of water, to form mercurous salts, when these are able to exist. Some, and probably all mercurous salts are oxidisable by air, in presence of water, when the temperature is much above 100° C.; but at and below that temperature, mercurous salts are not oxidisable in the air, or are oxidised so slowly that the effects of oxidation are not recognisable, owing to the effects of dissociation. Mercurous oxide is oxidisable at the ordinary temperature. It was also found that mercurous nitrate, in presence of water, is converted into mercuric nitrite and nitrate by the action of heat and light.—A. S.

*Glycerophosphates, A Simple Method of Preparing.*  
Delage. Bul. gén. de thérap. (Sec. Pharm. J. 1, 225).

ONE part by weight of phosphoric acid, sp. gr. 1.454, is mixed in a flask with one and a half parts of glycerin, sp. gr. 1.242. The flask is furnished with a double-bored cork provided with a thermometer and an exit tube. It is then gradually heated in the ordinary way, over a Bunsen flame. At 120° the liquid assumes a straw colour, and as the temperature slowly rises, it gradually darkens, until 190° is reached, when the colour is that of dark beer, and vapours of acrolein are given off. The heat is removed, and the vessel allowed to cool, a viscous mass resulting. 100 grms. of phosphoric acid and 150 grms. of glycerin should require about 40 minutes to complete the reaction.

To obtain glycerophosphate of lime, the resulting liquid is poured, in small quantities at a time, into an excess of a mixture of 50 grms. of lime to 250 grms. of water. The mixture is stirred, and when effervescence ceases, allowed to stand for six hours and then filtered. To the faintly yellow clear filtrate, half its volume of 90 per cent. alcohol is added, which throws down a flocculent precipitate of glycerophosphate of calcium. This is collected, washed

with alcohol of the same strength, re-dissolved in water, re-precipitated with alcohol, and dried at as low a temperature as possible in a desiccator. In this manner a white powder is obtained, consisting of masses of microscopic crystals, soluble in about 20 parts of water, 100 grms. of phosphoric acid yielding about 6 grms. of this salt. From the mother-liquors another salt, having the composition of an acid glycerophosphate, is obtained. This is not precipitated by alcohol.

The glycerophosphates of sodium and potassium can only be obtained in solution. Those of magnesium, strontium and lithium are readily obtained from their carbonates in a similar manner to the lime salt. The iron salts are easily prepared, ferric glycerophosphate being obtained by the action of glycerophosphoric acid on moist ferric hydrate, and precipitating the solution with alcohol. The ferrous salt is prepared in a similar way, using the ferrous carbonate.

The author gives the following reactions for the pure salts:—In aqueous solutions they are precipitated by heat. Alcohol and ether precipitate them. They give no immediate precipitate with ammonium phosphomolybdate, nor with magnesium mixture, nor with uranium acetate. The white silver nitrate precipitate is soluble in an excess of water. The white precipitate given by lead acetate is soluble in acetic acid. When treated with absolute alcohol, no residue should be obtained on evaporation.—J. O. B.

*Hydroxylamine Sulphate, Economic Preparation of.*  
E. Divers and T. Haga. J. Coll. Science, Imp. Univ. of Japan, 1897, 9, [2], 291—293.

A CONCENTRATED solution of commercial (95 per cent.) sodium nitrite (2 mols.) and sodium carbonate (1 mol.) is treated with sulphur dioxide till just acid, the liquid being kept well agitated at -2° to -3° C. A few drops of sulphuric acid are added and the mixture gently warmed, when the oximidosulphonate formed at first, rapidly hydrolyses into oxyamidodisulphonate and sodium bisulphate. The solution of these salts is kept at 90°—95° C. for two days, at the end of which time all oxyamidodisulphonate will have been converted into hydroxylamine sulphate and sodium bisulphate, only a very small trace of ammonium salt being produced. At 80°—85° C., five days are necessary, but practically no ammonia is formed; at 70° C. three weeks at least are necessary; whilst at the ordinary temperature, much oxyamidodisulphonate remains after several months. If the solution be kept boiling, seven or eight hours are sufficient to decompose all sulphonate, but at least one-third of the hydroxylamine is converted into ammonia, whilst another third is wasted as a practically inseparable mixture of its sulphate with ammonium sulphate.

To ascertain whether all the sulphonate is decomposed, excess of barium chloride is added to a little of the solution which is then filtered and boiled with potassium chlorate, thus converting any sulphonate into sulphate. When sulphonation is complete, the solution is neutralised with sodium carbonate, using methyl orange as indicator, evaporated till it weighs 10.5 to 11 times as much as the sodium nitrite taken, and then cooled to 0° C. or lower, when nearly all the sodium sulphate will crystallise out. The mother-liquor evaporated sufficiently and cooled to the ordinary temperature, yields hydroxylamine sulphate, the mother-liquor from which, very slightly diluted and cooled below 0° C., gives a little more sodium sulphate and can be worked for hydroxylamine sulphate as before. The hydroxylamine sulphate is purified by re-crystallisation. Sodium nitrite on the small scale yields, by this method, nearly its own weight of pure hydroxylamine sulphate, and on the large scale, the theoretical yield of 118.84 per cent. could no doubt be more nearly approached.—A. S.

*1-Phenyl-3-Methyl-5-Pyrazolone, Constitution of Acid Derivatives of.* Fr. Stolz. J. prakt. Chem. 55, 145—171.

ACCORDING to Nef (Annalen, 266, 155) the action of benzoyl chloride and soda lye on pyrazolone or of benzoyl

chloride on silver pyrazolone yields phenylmethyl-benzoyl-pyrazolone melting at 75° C. and having the formula—

This formula is based on the assumption that the silver in silver pyrazolone is in the position 2, and he further states that this latter compound when acted on by methyl iodide yields only antipyrine. The author's investigations show that not only is this latter reaction incomplete but also that the action of benzoyl chloride on silver pyrazolone does not yield exclusively pyrazolone. As a matter of fact this and other acyl derivatives which have been prepared by Autenrieth (Ber. 29, 1639), Himmelbauer (J. prakt. Chem. 54, 177 *et seq.*), and by the author are oxygen esters, i.e., are 5-derivatives of pyrazolone, and for the following reasons:—The action of methyl iodide on benzoylphenylmethylpyrazolone gives an iodomethylate which on warming with dilute alkali decomposes quantitatively into antipyrine, benzoic acid and hydriodic acid.

Antipyrine, (1-phenyl-2-alkyl-3-methyl-5-pyrazolone), gives characteristic reactions with ferric chloride and nitrous acid which are not shown by 1-phenyl-3-methyl-5-alkyloxypyrazolone, and further, the antipyrines are easily soluble in water but sparingly so in ether and petroleum spirit, whereas the acid derivatives obtained by Himmelbauer as analogues of the alkoxy derivatives are to be considered as oxygen esters, since they are insoluble in water but easily so in ether and petroleum spirit and do not give the ferric chloride or nitrous acid reactions of the antipyrines. The alkyl carbonic esters are similarly constituted, since they correspond in their properties (solubility and reactions, with nitrous acid and ferric chloride) to the pyrazole-5-oxyacetic esters but differ from the pyrazolone acetic esters. The former are obtained by reacting with sodium pyrazolone on chloroacetic ester, whilst the pyrazolone 2-acetic acids are produced by the addition of halogen acetic ether to 5-alkyloxypyrazole and subsequent removal of the alkyl group. Himmelbauer states that the methyl carbonic ester when distilled *in vacuo* yields antipyrine (about 40 per cent. of theory) together with methoxypyrazole, and he gives this in support of his view that the compound is a 2-derivative but in reality a molecular transformation takes place, and, for instance, 1-phenyl-3-methyl-5-methoxypyrazole is converted into the 2-derivative like the transformation of *p*-methoxyquinoline into *m*-methylquinoline. Hence this is a further proof that the compounds are 5-derivatives which are converted first into alkyloxypyrazoles and subsequently into antipyrines.—T. A. L.

#### Phenacetin brominated in the Benzene Nucleus. W.

Vaubel. J. prakt. Chem. 55, 217—219.

In a previous paper (J. prakt. Chem. 52, 421) the author described a bromo-derivative of phenacetin produced by direct bromination, as an oil probably identical with that obtained by Staedel (Annalen, 217, 73). The substance is now found to be a solid, melting about 20° C. but frequently remaining superfused. On hydrolysis, and subsequent removal of the amido group, a viscid oil is obtained, having a peculiar odour, and capable of taking up more bromine. The probable formula of bromophenacetin is  $1.2.4.\text{C}_6\text{H}_3\text{Br} \cdot \text{NHC}_2\text{H}_4\text{O} \cdot \text{BrOC}_2\text{H}_5$ .—T. A. L.

*Bases, Organic; The Use of Potassium-Bismuth Iodide in the Preparation of.* E. Jahns. Arch. der Pharm. 235, 151—156; Chem. Centr.-Bl. 1897, [1], 817.

THE author recommends potassium-bismuth iodide solution as a means of precipitating bases soluble in water, the separation from the extract in this way often being quantitative. The bismuth-iodide solution is prepared according to Krantz' prescription. 80 grms. of bismuth sub-nitrate are dissolved in 200 grms. of nitric acid (sp. gr. = 1.18), the solution poured into a concentrated aqueous solution of 272 grms. of potassium iodide, and, after crystallising

out the potassium nitrate, is made up to a litre. This solution gives precipitates with dilute sulphuric acid solutions of narcéine, solanine, veratrine, creatinine, &c., and also with bitter principles, glucosides, and albumins. It is best, in the case of solutions of vegetable matters, to first separate the colouring matters and albumins by precipitating with lead acetate. The excess of lead is precipitated from the filtrate by sodium phosphate, the filtered liquid evaporated, mixed with sufficiently dilute sulphuric acid, and precipitated with the bismuth iodide solution. The red precipitate is washed, and whilst still moist, triturated with silver carbonate till the red colour disappears, and the filtrate ceases to give the iodine reaction. A solution of the pure base or its carbonate is thus obtained, the dissolved traces of silver being removed by sulphuretted hydrogen. The bismuth precipitate may also be decomposed by boiling with barium carbonate and water, the barium accurately precipitated from the filtrate by  $\text{H}_2\text{SO}_4$ , and the HI removed by saturating with silver carbonate. By this method, cholia was detected in *Flor. chamomill. vulg.*, *Herb. millefol.*, *Herb. meliloti*, *Fol. malva*, *Herb. cochlear.*, *Fruct. anisi, vulg.*, *Cort. sambuci*, and *Sem. robinia pseudacacia*. The author also found that the alkaloid, bursine, discovered by Bombelon in *Capsella bursa pastoris* is identical with cholin. Cholin was found to be present in tolerably large quantities (up to 0.2 per cent.), together with somewhat less betain, in the seeds of *Lathyrus sativus* and *L. cicera*.—A. S.

*Aloin, Separation of, from Aloes.* G. L. Schäfer. Pharm. Zeits. für Russl. 1897, 36, 65.

THE author avails himself of the fact that aloin forms insoluble compounds with the alkaline earths in the presence of ammonia, from which it may subsequently be liberated by treatment with an acid. 50 grms. of aloes are dissolved in 300 c.c. of hot water, acidulated with a few drops of hydrochloric acid; after cooling, the liquid is poured off from the deposited resin; 50 c.c. of 20 per cent. ammonia solution are then added, followed by a solution of 15 grms. of calcium chloride in 30 c.c. of water; the mixture is thoroughly agitated and allowed to stand for 15 minutes; the precipitated calcium aloin is then collected and pressed, or drained on a centrifugal machine. The drained mass is triturated in a mortar with a slight excess of hydrochloric acid, the mixture dissolved in a minimum quantity of boiling water, filtered, the filter washed with a little boiling water, cooled, and crystallised at a low temperature by means of ice. From 15 to 30 per cent. of well-crystallised light yellow aloin is thus obtained from various kinds of commercial aloes.—J. O. B.

*Scammony, a Sample of Spurious.* I. W. Thompson. Pharm. J. 1897, 54, 245.

THE specimen consisted of irregular broken pieces, apparently portions of a cube, about half an inch in thickness, greenish black, hard and horny, breaking with a resinous fracture, and very difficult to powder.

The following figures were obtained on analysis:—

Soluble in ether, 0.4; in alcohol, 2.0; in water, 42.6; starch and cellular tissue, 43.0; and moisture, 12.0 per cent.

It yielded 2.12 per cent. of ash. The portion soluble in water was evidently gum, apparently gum acacia. The insoluble portion consisted very largely of starch. The sample was marked "Scammony," accompanied by a statement that it contained 84.864 per cent. of scammonin. It was said to be of German origin.—J. O. B.

*Kryofine, A New Antipyretic.* Pharm. Zeit. 1897, 42, 283.

A NEW derivative of parphenetidine, phenetidine-methylglycolate has been introduced to medicine under the name of kryofine. It is a condensation product obtained by heating together parphenetidine with methyl-glycolic acid as shown by the equation—

It forms white crystalline needles which melt at  $98^{\circ}$  to  $99^{\circ}$  C. These are odorless and tasteless, very sparingly soluble in cold water (1 in 600), but more readily so in hot water (1 in 52). The solution is bitter and burning in taste. In therapeutic effect, according to Eichhorst, 0.5 grm. of kryofine is equivalent to 1.0 grm. of phenacetin. If kryofine fail in certain cases, it has been found that the other synthetic antipyretics are also without reaction. Kryofine possesses useful anti-neuralgic properties as well.—J. O. B.

*Pilocarpine and Pilocarpidine, Further Contribution to the Study of.* A. Petit and Polonovski, J. Pharm. Chim. 1897 (10), 5, 475; (see also this Journal, 1897, 461).

*Commercial Salts of "Pilocarpine."*—These almost invariably consist of the mixed salt of the two bases, pilocarpine and pilocarpidine; this is notably the case with the nitrate, specimens of which are not unfrequently met with containing 50 per cent. of pilocarpidine. This impurity may be detected by the crystals being ill-defined, instead of definite, and by the lowering of the melting point and of the optical rotation. Pure pilocarpine nitrate melts at  $177^{\circ}$ – $178^{\circ}$  C., while the specimens containing 50 per cent. of pilocarpine soften at  $140^{\circ}$  C. and are completely decomposed at  $150^{\circ}$  C. The influence on the optical rotation is so definite that by the data obtained by its observation, the respective amount of the two nitrates present may be calculated by Landolt's formula.

*Pilocarpidine not a Decomposition Product.*—The authors consider that pilocarpidine exists naturally in the plant, and not as a decomposition product, as stated by Hardy and Calmels. Boiling water alone, in the absence of strong acids and alkalis, cannot be capable of forming large quantities of pilocarpidine, its action upon pilocarpine being but slight. Even when the extraction and separation of the alkaloids is conducted wholly without heat, notable quantities of pilocarpidine are obtained; again, operating under the same conditions with different species of jaborandi, the yield of pilocarpidine is very variable, oscillating between 5 and 75 per cent. of the total alkaloids, according to the variety of leaf employed. It is found also that the stems usually give markedly more pilocarpidine than the leaves of the same plant.

*Pilocarpic and Pilocarpidic Acids.*—The two bases are considered to be the anhydrides of pilocarpic and pilocarpidic acids respectively. Upon the addition of dilute alkali to a solution of pilocarpine, hydrolysis takes place; if phenolphthalein be used as an indicator, the colour gradually disappears in the cold, and rapidly on warming. In this way one equivalent of alkali is found to combine with each equivalent of pilocarpine. On exactly neutralising, the optical rotation is found to remain identical with that of the sodium compound, and notably lower than the figure for pilocarpine. On adding an excess of acid, however, gradual dehydration of the pilocarpic acid takes place, pilocarpine is regenerated and ultimately the rotation is brought back to that of pilocarpine. In this manner the progressive hydration of the base by alkaline solution, and the subsequent dehydration in an acid solution of the acid at first formed, may be followed by polarimetric observation.

Although these acids have hitherto been regarded as hypothetical, the authors have succeeded in preparing them in a free state, by decomposing the barium salts with an exact equivalent of sulphuric acid. They are thus obtained in the state of amorphous varnishes, very soluble in water but insoluble in chloroform or in ether; on heating, partial dehydration takes place, with partial regeneration of the alkaloids. In the presence of free acid this is more rapid and, on heating, is complete. The only observed difference in the behaviour or composition of the two acids or of their salts, is the fact that pilocarpidic acid and its compounds are levogyrate.

The authors conclude that pilocarpine and pilocarpidine are isomers, both having the formula  $C_{11}H_{16}N_2O_2$ . The assumption that pilocarpidine differs from pilocarpine in having a methyl group less, giving it the composition  $C_{10}H_{14}N_2O_2$ , is not borne out by the figures obtained by analysis, nor by theoretical considerations. If the con-

stitution assumed for the two bases by Hardy and Calmels be correct, it is impossible for pilocarpidine to possess an anhydride group, although the authors now show that in its behaviour towards alkalis it is exactly similar to pilocarpine; in fact, the only marked differences observed between the two alkaloids and their products lie in their physical constants.—J. O. B.

*Holocaine, A New Anesthetic.* G. Gutmann, Deutsch. Med. Wochenschr. 1897, [11], 165–167; Chem. Centr.-Bl. 1897, [1], 875.

According to Täuber, holocaine is *p*-diethoxyethenyl-diphenylamine and is prepared by the combination of molecular quantities of phenacetin and *p*-phenetidine, with separation of water—

The beautiful crystalline base is insoluble in water, volatilises at  $121^{\circ}$  C., and forms soluble salts. The hydrochloride forms minute white needles soluble in boiling water. The cold saturated aqueous solution of the hydrochloride contains 2.5 per cent., tastes faintly bitter, reacts neutral and is not altered by boiling. On boiling the solution in glass vessels, it sometimes becomes turbid, owing to a small quantity of the alkali of the glass being dissolved, and the insoluble amidine base set free. Porcelain vessels should therefore be used when dissolving the hydrochloride. The author considers holocaine better than cocaine as a local anesthetic, as it acts efficiently in one to two minutes.—A. S.

*Cedar-Wood, Essence of.* L. Rousset. Bull. Soc. Chim. 1897, 17, 485–489.

PURE essence of cedar-wood was subjected to fractional distillation *in vacuo*, 80 per cent. of a hydrocarbon boiling at  $125^{\circ}$ – $130^{\circ}$  under a pressure of 9 mm., and a solid product distilling at  $149^{\circ}$ – $155^{\circ}$  under 8 mm. were obtained, the intermediate portion being insignificant.

*Cedrene*,  $C_{15}H_{22}$ .—This hydrocarbon, distilled over sodium, boils at  $131^{\circ}$ – $132^{\circ}$  under 10 mm. It is optically active,  $\alpha_D = -47^{\circ} 54'$ . The hydrocarbon absorbs bromine, hydrochloric and hydrobromic acids, but the compounds spontaneously decompose and on distillation yield cedrene. Oxidised by chromic acid in acetic acid solution, the ketone  $C_{15}H_{22}O$ , cedrone, is obtained. This distils at  $147^{\circ}$ – $151^{\circ}$  under 7.5 mm., does not combine with sodium bisulphite, but yields an oxime boiling at  $175^{\circ}$ – $180^{\circ}$  under 8 mm.

Cedrone on reduction gives the alcohol isocedrol  $C_{15}H_{26}O$ , a viscous liquid of boiling point  $148^{\circ}$ – $151^{\circ}$  under 7 mm. A benzene ether was obtained. Cedrone treated with sodium hypobromite and potassium iodide gives iodoform, and hence probably contains the acetyl group.

Cedrene, by further oxidation, gives a viscous monobasic acid  $C_{12}H_{18}O_3$ , and some dimethylketone. Oxidation by nitric acid or alkaline permanganate does not give favourable results. By the action of sulphuric or glacial acetic acid cedrene gives no hydrate.

*Cedrol*,  $C_{15}H_{26}O$ .—The solid product of the distillation after repeated recrystallisation from methyl alcohol forms fine white needles melting at  $84^{\circ}$ . A molecular weight determination and analysis, point to the formula given. Cedrol is optically active. Treated with acetic anhydride at  $100^{\circ}$  it is transformed into an ester and partly into a hydrocarbon  $C_{15}H_{24}$ . Benzoyl chloride gives rise to no ester, but produces the same hydrocarbon. Cedrol has thus properties very different from those of the alcohol obtained by reduction of cedrone. Oxidised by chromic acid, a sesquiterpene boiling at  $115^{\circ}$ – $117^{\circ}$  under 6.5 mm. is obtained, no aldehyde or ketone being formed. Cedrol, therefore, appears to be a tertiary alcohol.—A. C. W.

*Geranium Essence, Researches on.* E. Charabot. Bull. Soc. Chim. 1897, 17, 489–492.

THE author finds that the rotatory power of geranium essences is decreased by saponification, hence they must contain a levo-rotatory ester. This ester is almost entirely contained in the part of the essence which is most easily volatile with steam; essence of palmarosa contains no similar levo-rotatory ester.—A. C. W.

*Tea, Essential Oil of.* Schimmel's Rep., April 1897, 40.

THE essential oil of tea leaves which has so far been obtained in the proportion of only 0.006 per cent. had the following characters. The specific gravity was 0.866, and the optical rotation slightly levo-rotatory,  $0.11'$  in a 200 mm. tube. Fractional distillation separated the oil into two parts, one boiling below  $170^{\circ}\text{C}$ . and the other above that temperature. The lower boiling fraction contained a body boiling between  $153^{\circ}\text{C}$ . and  $151^{\circ}\text{C}$ . having a pungent fusel-oil like odour; the formula for this was found to be  $\text{C}_8\text{H}_{12}\text{O}$ . It formed a benzoyl compound and an acetic ester, being evidently of an alcoholic nature; by oxidation with bichromate of potassium and sulphuric acid a liquid was obtained which appeared to contain butyric acid.—J. O. B.

*Camphor Wood Oil, Venezuelan.* Schimmel's Rep., April 1897, 45.

THE botanical source of the "camphor wood" from Venezuela, which was distilled, has not been determined. It gave 1.15 per cent. of volatile oil, which solidified to a crystalline mass at the normal temperature; the specific gravity was 1.155, and the optical rotation  $2^{\circ} 40'$  in a 100 mm. tube (temperature not stated). The crystals drained from the liquid and recrystallising from alcohol were large, well-formed prisms melting at  $28.5^{\circ}\text{C}$ . With alcoholic potash a compound crystallising in plates which melt at  $55.56^{\circ}\text{C}$ . was obtained. This was evidently apiol, which was present in the oil to the extent of 90 per cent. Its characters agreed in every particular with apiol derived from parsley oil.—J. O. B.

*Wormwood Oil.* Schimmel's Rep., April 1897, 47.

HITHERTO only one definite constituent of this oil, thujone, has been known. A pure sample of the oil was therefore examined; this had a specific gravity of 0.932. After removing the greater part of the thujone by means of sodium bisulphite and saponifying the residue with alcoholic potash, the residue of steam distillation was found to contain palmitic acid; acetic and isovaleric acid were also found to exist as esters in the oil. The lowest fractions boiling between  $158^{\circ}\text{C}$ . and  $168^{\circ}\text{C}$ . were found to contain phellandrene; pinene, if present, existed in so small a trace that it could not be isolated. It is evident that an oil containing much pinene can only be adulterated. A ready test for the freedom of wormwood oil from adulteration with turpentine consists in distilling off about 10 per cent. of the sample. One part of this distillate should give a clear solution with 40 parts of 80 per cent. alcohol. Besides thujone a higher boiling body distilling between  $210^{\circ}$ — $215^{\circ}\text{C}$ . was obtained; this proved to be thujyl (tanacetyl) alcohol. By quantitative saponification of the oil before and after acetylation, the amount of thujol free and as acetate was found to be 24.2 per cent. Several commercial specimens of wormwood oil were found to be adulterated with turpentine.—J. O. B.

*Goldenrod, Canadian; Essential Oil of.* Schimmel's Rep., April 1897, 46.

THE oil of *Solidago canadensis* has been recently found to contain 85 per cent. of terpenes, mainly pinene, with a little phellandrene and dipentene, possibly also a little limonene. The higher fractions contain borneol, 5.8 per cent., and bornyl acetate, 3.4 per cent., with some cadinene. The close analogy in chemical composition between this oil and that of some of the pine needle oils is remarkable, considering the widely different botanical position of the two sources.—J. O. B.

*Schinus Molle (Pepper Tree), Essential Oil of.* Schimmel's Rep., April 1897, 41.

THE oil was distilled from the berries imported from Mexico; a yield of 5.2 per cent. of a light oil being obtained. This had an odour of phellandrene; the specific gravity was 0.850 at  $15^{\circ}$  and the optical rotation  $+46.1'$ ; with sodium nitrite and glacial acetic acid, it gave the characteristic reaction for phellandrene nitrite. Only traces of phenols could be found.—J. O. B.

*Mandarin Oil, Chemical Composition of.* Schimmel's Rep., April 1897, 21.

IN endeavouring to prepare citryl- $\beta$ -naphthocinebonic acid from the fractions of mandarin oil which contain citral, although the characteristic precipitate was obtained, it did not give, even after repeated crystallisations, the correct melting point for the pure substance. It commenced to melt at  $197^{\circ}\text{C}$ ., but was not fully melted until the temperature reached  $222^{\circ}\text{C}$ . It is, therefore, probable that this oil, like lemon oil, contains both citral and citronellal. The presence of limonene in the fraction boiling between  $175^{\circ}$  and  $179^{\circ}$  was indicated by preparing the dichlorhydrate, melting at  $49^{\circ}\text{C}$ ., and the tetrabromide melting at  $104^{\circ}$ — $105^{\circ}\text{C}$ . This fraction was strongly dextro-rotatory ( $+77^{\circ}$ ) and consisted mainly of dextro-limonene.—J. O. B.

*Lemon Oil, Influence of Climate on.* Schimmel's Rep., April 1897, 18.

THE influence of climatic variations on the constitution of lemon oil has been markedly shown during the last season in the northern and eastern districts of Sicily. The summer there has been cool with an abnormal rainfall. The oil produced in this part of the island was found to have an optical rotation two or three degrees below the normal standard, while that derived from the southern district, where the weather was hot and dry, retained its normal optical activity. Careful observations of the produce of each month during the season, has shown that atmospheric conditions have a distinct influence, not only on the optical behaviour of lemon oil, but also on the ester percentage of bergamot oil.—J. O. B.

*Lemon Oil, Absence of Pinene in.* Schimmel's Rep., April 1897, 20.

IN order to determine definitely if pinene could be regarded as a normal constituent of lemon oil, 50 kilos. of it were submitted to fractional distillation; after re-fractionation, the lowest boiling portion, which distilled at  $172^{\circ}\text{C}$ ., amounted to only 8 c.c., or 0.016 per cent. of the whole, and had none of the characters of pinene. If, therefore, that body be detected in a sample of lemon oil, it may with certainty be pronounced to be adulterated with turpentine. Recent investigations show that this form of sophistication is again being largely practised, specimens containing as much as 60 per cent. of oil of turpentine having been met with.

—J. O. B.

*Dill Oil.* Schimmel's Rep., April 1897, 15.

GERMAN dill oil, although differing markedly in odour from caraway oil, resembles it very closely in chemical constitution, and at present, no definite substance accounting for the variation in odour has been isolated. The peculiar dill-apiol detected in East Indian dill oil by Ciamician and Silber, is not found, it is said, in the German oil; no constituents of any importance with a boiling point above that of carvol having been isolated. The residue, on fractionation, gave only a small quantity of a paraffin, melting at  $64^{\circ}\text{C}$ . A specimen of English dill oil recently examined, was found to give, with sodium nitrite and glacial acetic acid, a marked reaction for phellandrene. With German oil this reaction was not obtained.—J. O. B.

*Damiana Oil.* Schimmel's Rep., April 1897, 15.

LEAVES of damiana (derived from several species of *Turnera*) distilled in Leipzig last year yielded about 1 per cent. of oil. This had a specific gravity of 0.943, which was much lower than that of a specimen distilled in 1888, which had a density of 0.970 and 0.980. The new sample was levo-rotatory, the index being  $-23.25'$ ; the saponification figure was 41.8. On standing, it deposited crystals resembling in appearance those of the stearoptene of rose oil; it is possible, therefore, that damiana oil may contain a paraffin. The oil has at present, no practical application.

—J. O. B.

*Culilaban Oil.* Schimmel's Rep., April 1897, 14.

FROM culilaban bark, derived from *Cinnamomum culilaban*, 4 per cent. of oil was obtained. This had a specific gravity

of 1.031 and possessed a strong odour of eugenol; the oil was dark in colour. The phenol was isolated and proved to be eugenol, giving benzoyl-eugenol, melting at  $70^{\circ}$ – $71^{\circ}$  C. After the removal of the eugenol, the remainder of the oil boiled between  $100^{\circ}$  and  $130^{\circ}$  C., under a pressure of 10 mm.; the main fraction boiling at  $125^{\circ}$  to  $130^{\circ}$  had a specific gravity of 1.031, the fractions with a lower boiling point being lighter than water. Distilled under normal atmospheric pressure, the fraction distilling between  $249^{\circ}$  and  $252^{\circ}$  C., gave, upon oxidation with potassium permanganate, veratric acid, with a melting point between  $170^{\circ}$  and  $180^{\circ}$  C. Analysis of the silver salt gave figures corresponding with the formula  $C_9H_9O_4Ag$ . This result, as well as the boiling point of the fraction, indicate methyl-eugenol. By bromination, tribromo-eugenol was obtained. Culilaban oil, therefore, consists, it is stated, mainly of eugenol with some methyl-eugenol, and a small amount of constituents of a lower specific gravity than water.—J. O. B.

#### Champaca Oil. Schimmel's Rep., April 1897, 11.

CHAMPACA oil, distilled from the fresh flowers of *Michelia champaca*, a native of Manilla, is a very fragrant, light-brown liquid, having a specific gravity of 0.938, the optical rotation is  $52^{\circ} 8'$  in a 100-mm. tube, and a saponification factor of 77.3. The oil is soluble in absolute alcohol, but is not easily dissolved in weaker spirit. The odour somewhat resembles that of Ylang-ylang, and, like it, champaca oil contains benzoic acid.—J. O. B.

#### Anise Oil, Adulteration of, with Fennel Oil Stearoptene. Schimmel's Rep., April 1897, 6.

FROM the fact that pure oil of aniseed is always slightly levo-rotatory ( $-1^{\circ} 50'$ ), while certain specimens of low-priced anise oil met with in commerce are dextro-rotatory, it is suspected that these latter are adulterated with the stearoptene of the cheaper fennel oil. Since this always retains a considerable amount of fenchone, which is strongly dextro-rotatory, its presence imparts an abnormal optical rotation to a mixture of anise oil. Anise oil which is not slightly levo-rotatory should therefore be rejected.—J. O. B.

#### Valerian Oil, Mexican. Schimmel's Rep., April 1897, 44.

THE root distilled was imported from Mexico, and was probably derived from *Valeriana mexicana*. On simple distillation no oil was obtained, and it was not until cohobation had been first performed that any product was yielded. The specific gravity of the oil thus finally obtained (an oil optically inactive) was 0.949 at  $15^{\circ}$  C.; it was entirely soluble in soda solution. The acid number, when titrated with alcoholic potash, was 415: equivalent to 89 per cent. of valerianic acid. There is, then, practically no true essential oil present in the root, but simply valerianic acid, which appears to exist in the free state.—J. O. B.

#### Bengal Cardamom Oil. Schimmel's Rep., April 1897, 43.

BENGAL cardamoms yielded 1.12 per cent. of a light yellow oil having a specific gravity of 0.920 at  $15^{\circ}$  C., and an optical rotation of  $12^{\circ} 41'$ ; the odour strongly recalled that of cineol. On distilling, the major fraction passed over below  $220^{\circ}$  C.; in this the supposed cineol was separated as hydrobromide, from which it was subsequently obtained in the pure condition by decomposing with water, when it was found to have all the physical and chemical characters of pure cineol, and to give, on oxidation, cineolic acid, melting at  $197^{\circ}$  C. Bengal cardamom oil has little of the characteristic aroma of cardamoms, and therefore is not likely to be useful commercially.—J. O. B.

#### Clove Oil. Schimmel's Rep., April 1897, 45.

THE body which gives to clove oil its fruity ethereal odour, which is not found in pure eugenol, has been isolated, and proved to be normal amyl-ketone,  $CH_3(CH_2)_4CO.CH_3$ , which has not been previously observed as a constituent of essential oils. It was obtained from the first fraction of clove oil, boiling between  $150^{\circ}$  and  $155^{\circ}$  C., and was purified from furfural by shaking with cold potassium permanganate

solution, after which it had a constant boiling point of  $151^{\circ}$  to  $152^{\circ}$  C. It is only present in the oil in extremely minute quantities.—J. O. B.

#### Basilicum Oil Distilled in Grasse. Dupont and Gueslain J. Pharm. Chim. 1897, 5, 129, 153.

THE oil was a somewhat thick yellowish fluid with a strong and characteristic odour. The specific gravity at  $15^{\circ}$  C. was 0.9154, and its rotation in a 100-mm. tube,  $7^{\circ} 10'$ . The chief constituents proved to be left-handed linalool and estragol. At ordinary atmospheric pressure, 80 per cent. of the oil distilled between  $190^{\circ}$  and  $220^{\circ}$  C. On re-fractionating this, two principal fractions were obtained, one boiling between  $195^{\circ}$ – $200^{\circ}$  C., and the other between  $205^{\circ}$ – $215^{\circ}$  C.

The former, which represented 60 per cent. of the original oil, proved to be levo-rotatory linalool, as shown by its physical properties, by its bromo derivative, and by the formation of linalyl acetate.

The second fraction, boiling between  $205^{\circ}$ – $210^{\circ}$  C., was found to be estragol. This was proved by transforming it into its propenyl isomer, anethol. This was effected by heating it on the water-bath with twice its volume of concentrated alcoholic potash for 24 hours. The mass was then heated with water, extracted with ether, the solvent removed, and the residual oil fractionated; the higher boiling fraction, distilling between  $225^{\circ}$  and  $230^{\circ}$ , was found to be anethol, solidifying below  $0^{\circ}$  C. and melting again at  $+21^{\circ}$  C.—J. O. B.

#### Filicic Acid, Researches on. G. Dacomo. Apoth. Zeit. 1896, 41, 812; J. Pharm. Chim. 1897, 5, 92, 447.

FROM the behaviour of hydroxylamine with filicic acid and the action of barium hydrate on the copper salt, it appears that this acid does not belong to the aromatic series, but is a fatty acid. It seems to be a  $\beta$ -ketone-aldehyde containing the nucleus—

When a mixture of filicic acid in benzene is added to an alcoholic solution of hydroxylamine and heated with calcium carbonate, a reddish-brown body is formed which, on distillation in a partial vacuum, leaves a brownish residue, with an odour of pyridine. On washing this with dilute soda and re-crystallising the insoluble portion from alcohol, a reddish powder composed of prismatic crystals is obtained. These have the composition  $C_{11}H_{15}O_4N$ ; that is to say, they are the anhydride of filicic acid,  $C_{11}H_{16}O_4NOH$ , and not the oxime. When methylic ether is used as a solvent of the filicic acid in the above reaction, an isomeric modification of the same anhydride is obtained.

When the copper salt of filicic acid is heated with baryta water, decomposition takes place at ordinary temperatures; the copper salt gradually dissolves and is then reduced, a precipitate of cuprous oxide resulting, and a slightly aromatic acetone-like odour is given off. At a temperature of  $50^{\circ}$ – $60^{\circ}$  C. reduction is complete in two or three hours. By this reaction, acetone, isobutyric, normal butyric, and dimethylmalonic acids are all products, and are all members of the series of fatty acids.—J. O. B.

## PATENTS.

*Xanthine Derivatives, Impts. in the Manufacture of, from Alkylated Uric Acids.* [Synthesis of Caffeine.] E. Fischer, Berlin. Eng. Pat. 10,004, May 11, 1896.

THE process consists in the preparation of the halogen derivatives of alkylated xanthines by treating tetra-alkyluric acids with the halogen compounds of phosphorus, and the production of trialkylated xanthines by reducing, in the usual manner, the halogen derivatives so obtained. By means of this process it is possible to prepare caffeine from tetramethyluric acid, and incidentally from uric acid. To convert tetramethyluric acid (the method for the preparation from uric acid is well known) into chloro-caffeine, it is heated in a closed vessel with five times its weight of phosphorus oxychloride for 10 hours at 160°—165° C. A clear brown liquid is formed, which, when evaporated and treated with water, gives a crystalline powder containing the chloro-caffeine. This is purified by heating with five times its weight of fuming hydrochloric acid at 130° C. for three hours; the hydrochloric acid solution is evaporated to dryness, the residue extracted with cold dilute caustic soda; the impurities having thus been converted into acids are removed, and chloro-caffeine remains behind, and may be obtained pure by a single recrystallisation from hot alcohol. Its reduction to caffeine is then accomplished in the usual way.—J. O. B.

*Alkylated Uric Acids, Impts. in the Preparation of.* E. Fischer, Berlin, Germany. Eng. Pat. 10,005, May 11, 1896.

ALKYLATED uric acids are prepared by the action of halogen alkyls upon the alkaline salts of uric acid, or on the alkyl derivatives of the acids. Details are given of the methods for (1) converting uric acid into alpha-monomethyluric acid; (2) converting alpha-methyluric acid into tetramethyluric acid; (3) converting alpha-dimethyluric acid into tetramethyluric acid; (4) converting beta-trimethyluric acid into tetramethyluric acid; (5) converting alpha-dimethyluric acid into benzyl-dimethyluric acid; (6) converting beta-trimethyluric acid into benzyl-trimethyluric acid; (7) converting alpha-dimethyluric acid into tetra-methyluric acid in the dry way.—J. O. B.

*Aromatic Aldehydes, Manufacture of.* O. Imray, London. From The Farbwerke vorm. Meister, Lucius, and Brüning, Höchst a/Main, Germany. Eng. Pat. 10,689, May 18, 1896.

THE process consists of the oxidation of benzylaniline, its homologues or nitro-substitution products, and of separating in the usual way, by means of diluted mineral acid, the benzylidene or nitrobenzyl thus obtained into aniline bases and aldehyde. The following process is followed for the manufacture of benzaldehyde:—100 kilos. of benzylaniline and from 500 to 1,000 litres of water are placed in a large retort fitted with an agitator; during agitation and boiling, the following mixture is run in gradually, during a few

hours. Potassium or sodium bichromate, 50 kilos; water, 200 litres, acidulated with hydrochloric acid (21° B.), 165 kilos., or its equivalent of sulphuric acid. Distillation of water and benzaldehyde soon results. An equivalent proportion of benzyltoluidine may be substituted for the benzylaniline. By substituting 120 kilos. of *o*-nitro-benzylaniline or its equivalent of *o*-nitro-benzyltoluidine, *o*-nitro-benzaldehyde crystallises out from the distillate on cooling; by substituting the equivalent "para" modifications, the corresponding "paraldehyde" is obtained. From neutral solutions *o*-nitro-benzaldehyde may be made as follows:—23 kilos. of *o*-nitrobenzylaniline (or the equivalent of *o*-nitro-benzyltoluidine, or *o*-nitro-benzylxyldine) are dissolved in acetone and then a cold aqueous solution of 12.5 kilos. of potassium permanganate is run in, the temperature being kept at about 10° C. The solution is filtered and the acetone distilled off. Hydrochloric acid (15 kilos.) is then added to the aqueous residue, when *o*-nitrobenzaldehyde crystallises out; it is collected, washed, and purified by steam distillation.

—J. O. B.

*Pharmaceutical Compounds [Iodine Compounds from Sponges, Scaevolds, and similar Material], Manufacture of.* H. E. Newton, London. From The Farbenfabriken vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 11,458, May 26, 1896.

MEDICINALLY active iodine compounds are obtained from sponges, laminariae, fucus, and similar material by the action of dilute acids, followed by extraction with dilute alkalis, and then precipitating the alkaline extract by acids or by alcohol. The bodies so obtained are claimed as new, and available for medicinal purposes. Five parts of common sponge are heated with 20 to 30 parts of 5 per cent. sulphuric acid at 100° C. for 12 to 15 hours. The liquid is filtered when cold and the insoluble residue again treated with soda solution (containing 1 or 2 per cent. of NaIO) to extract the iodine compounds. The filtered alkaline liquid is made acid, when the iodine compounds are precipitated as a red-brown powder, which is collected, washed, and dried. After treatment with acid, the residue may, if necessary, be purified by extraction with boiling alcohol, in which the iodine compounds are insoluble. The residue is then extracted with the weak alkaline menstruum as described; or the material may be treated direct with alkali without the previous extraction with acid.

—J. O. B.

*Albuminous Compounds, New [with Formic Aldehyde], Manufacture of.* O. Imray, London. From The Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst a/Main, Germany. Eng. Pat. 11,878, June 1, 1896.

By allowing aqueous solution of white of egg to act upon formic aldehyde and then boiling off the excess of the latter and evaporating the product to dryness, a modified albumin is obtained. This is soluble in water, does not coagulate on boiling, and is not precipitated by soda or ammonia; alcohol and acetone precipitate it, and the substance thrown down, when dried, is still soluble in water.

The new product is thus obtained. Four kilos. of white of eggs are mixed with about 25 grms. of formic aldehyde (40 per cent.) and left for several days. Water is then added and the solution boiled until the excess of aldehyde is driven off, more water being added if necessary. The solution is then filtered, evaporated at a low temperature to the desired concentration, or to dryness *in vacuo*.—J. O. B.

*Salicin, Saligenin, and Free Hydrochloric Acid; A Compound of good keeping Property, of.* W. P. Thompson, London. From Ludwig Sell and Co., Pasing-Munich, Germany. Eng. Pat. 12,434, June 6, 1896.

A FLUID extract of horse-chestnut is mixed while hot with an equal weight of salicin, the mixture warmed on the water-bath for 20 minutes, or until a reaction for saligenin is obtained. Twice as much salicin is then incorporated with the warm mass, and the whole is kneaded thoroughly, spread on glass plates, and dried at 19° C. The resulting product is a composition which is said to keep well, and contains salicin, saligenin, glucose, and free hydrochloric acid.—J. O. B.

**Tobacco, Impts. in Manufacture of** [*Combination of Essential Oils and Aromatic Herbs with*]. R. Pserhofer, Vienna. Eng. Pat. 12,736, June 10, 1896.

THE finely powdered leaves of *Mentha piperita*, *Mentha crispata*, *Eucalyptus* var. species, *Thymus vulgaris* or *Melissa officinalis*, are mixed directly with tobacco, or the tobacco is moistened with solutions or emulsions of the volatile oils, or the "stearoptenes" of the oils. (Or the "stearoptenes" of menthol, eucalyptol, or of melissa oil "in a finely powdered state," are mixed with tobacco. Or the oils or stearoptenes are put into a distillatory apparatus, and the tobacco is impregnated with the vapours. —J. O. B.

**Artificial Musk, Impts. in Manufacture of.** O. Huray, London. From "The Fabriques de Produits Chimiques de Thann et de Mulhouse," Thann, Alsace. Eng. Pat. 14,552, July 1, 1896.

THE artificial musk is obtained by nitrating dimethyl-butyl-benzaldehyde, or its homologue, methyl butyl benzaldehyde, or its substitution product, methylbutyl-methoxy-benzaldehyde. For instance, one part of dimethyl-butyl-benzaldehyde is put into 10 parts of nitric acid (99 to 100 per cent.) and kept cool; after standing for some time, the mixture is poured on ice, the precipitate collected, washed, and crystallised from alcohol, from which it separates in white plates melting at 112°–115° C. In composition it is dinitro-dimethyl-butyl-benzaldehyde; any of the above-mentioned aldehydes may be substituted for the dimethyl-butyl-benzaldehyde in this process. —J. O. B.

**Artificial Musk, Improved Process for Manufacture of.** Adolf Blaile, Zürich, Switzerland. Eng. Pat. 24,568, Nov. 3, 1896.

By dissolving terpenes in alcohol, pouring the solution into sulphuric acid, and then the latter mixture into nitric acid, and finally the whole into water, the crude musk-smelling substance is obtained as a brown amorphous mass.

100 parts by weight of terpinol are mixed with an equal weight of ethylic alcohol of 96 per cent. strength, to form a clear solution, which is poured into 1,000 parts of sulphuric acid (66° B.), with constant stirring and cooling, the mixture being stirred for 6 hours. The resulting compound is then poured into 1,000 parts of concentrated nitric acid, free from chlorine, with constant stirring, and the temperature not allowed to rise above 8° C. The mixture is then warmed to about 70° C. for 4 hours, then cooled, and poured into 20,000 parts of water, with vigorous stirring. The new perfume, in the crude state, then forms a brown deposit, which is collected. This may be further purified by washing with hot water until free from acid, then extracting with petroleum ether, or some other suitable solvent, until a yellow crystalline body is obtained, having a delicate musk-like odour. Instead of terpinol, eucalyptus or turpentine oils, or oils from fossil resins, such as oil of amber, retene oil, or other bodies having similar chemical properties, may be employed. —J. O. B.

**Acetanilide or Acetoluides, Process for Producing.** J. Corry Fell, London. From W. J. Matheson and Co., New York City, U.S.A. Eng. Pat. 6220, March 9, 1897.

By treating aniline or the toluidines, under pressure, with more dilute acetic acid than the glacial acid hitherto employed—viz., containing 50 or 33 per cent. of real acid—or even by using crude pyroligneous acid, acetanilide or the acetoluides are obtained. When 1 part of aniline with  $1\frac{1}{2}$  to  $1\frac{3}{4}$  of 50 per cent. acetic acid are heated together under pressure to between 150° to 160° C. until acetylation is complete, the resulting liquid, on cooling, solidifies into a mass of crude acetanilide, which may be purified by fractional distillation or by washing, and subsequent crystallisation. The same method and reactions apply to the toluidines. The quantity of acid employed should be in excess of the theoretical equivalents. —J. O. B.

**Preserving Substances** [*Vegetable, containing Aromatic Oils*], Improved Process for. H. Humbser, Fürth, Bavaria. Eng. Pat. 6064, March 8, 1897.

THE process is intended for preserving vegetable substances, such as hops, which contain aromatic oils readily

volatilising on heating. Air, dried by forcing it into a very cold chamber, where it deposits its moisture, is then warmed, so as to enable it to take up moisture again, and conveyed through storage chambers containing the substance to be preserved, where it again takes up moisture. The warming of the air can be effected by means of a stove-pipe, or it can be passed through a coil of thin pipe exposed to the open air. —N. H. J. M.

## XXI.—PHOTOGRAPHY.

**Photography and Photo-Mechanical Processes, Recent Progress in.** J. M. Eder and E. Valenta. Dingl. Polyt. J. 1897, 304, 67 and 92.

KOGELMANN has lately stated that the effect produced on bromide plates by ordinary white light may be removed to a certain extent by exposure to the red rays; whilst among new sensitisers for this end of the spectrum, Eberhardt recommends that after immersion in 1 per cent. ammonia for 1 minute, the plates should be dipped for 3 minutes in a bath containing 3 c.c. of a 0.2 per cent. solution of Beyer's Nigrosin B, 1 c.c. of ammonia, and 100 c.c. of water.

Teape prepares a collodio-chloride emulsion for positives by means of zinc chloride and silver nitrate, the developer being quinol. In the manufacture of bromide emulsions, Scheers makes use of urea in order to regulate the action of the ammonia and to hasten the ripening of the emulsion in the cold. Colby claims the addition of acetyl chloride, which increases the sensitiveness. Vogel holds that the character of the gelatin itself notably affects the keeping qualities of the plates. He tests it by dissolving a sample in 10 parts of water, heating the liquid with a 10 per cent. solution of ammoniacal silver nitrate; if a yellow or brown colour is produced, the gelatin is not adapted for the preparation of emulsions by the ammonia process.

Hanff states that the presence of thiosulphate in the metal developer increases its strength and makes its action more like that of pyrogallol. He gives the following formula:—(A.) Metol, 15 parts; sodium sulphite, 150; water, 1,000. (B.) Sodium carbonate, 350; "hypo," 1; water, 1,000. 20 parts of A., 10 of B., and 30 of water are used for development. Neuhaus advises a similar method of procedure in the case of amidol.

Anthion (potassium persulphate; this Journal, 1896, 50), which is frequently employed as a "hypo-eliminator," in Gribb's hands produces markings on the film.

To remove the gelatin film from its support—an operation frequently involved in photo-mechanical work—Valenta suggests that the plate should be immersed for 10 minutes in a bath of 1 part of formalin diluted with 5 or 10 parts of water, then dried, levelled, and coated with gelatin, 75 grms.; water, 500; and glycerin, 10 (previously filtered through flannel). After being dried again, it is soaked for 10 or 15 minutes in a mixture of glycerin, 50 parts; alcohol, 50; and water, 1,000, when the film can be readily stripped off the glass. A clean glass plate is then levelled, coated with 5 per cent. plain collodion, and the solvents allowed to evaporate; the moist negative film is "squeezed" on to it, gelatin side down, and after the whole has become dry, it may be stripped without danger of causing any distortion.

G. and H. Beneke have introduced a matt collodion paper for positives which, it is claimed, will not crack or peel off, and will lend itself well to retouching. It is made by coating baryta paper with an emulsion containing only a small amount of collodion. Two gelatin papers have been put on the market, called "gelatoid" and "universal" paper respectively, having the film rendered insoluble by treatment with formalin, so that they may be worked, like the collodion papers, in warm baths.

Among new toning agents for silver bromide, solutions are being sold of uranium nitrate, potassium ferricyanide, and ferric chloride in about 1 per cent. strengths, which, on being mixed together in varying proportions, yield brown, red, green, and blue pictures; the process is known as "virage panchromatic." For chloride prints, Barnstable recommends a small addition of potassium platino-chloride to the ordinary gold and sulphocyanide bath.

According to Kuhn, by the partial or total substitution of potassium palladium chloride for the corresponding platinum compound in "platinotype," brown or sepia prints may be obtained, which gain considerably in depth and brilliancy during fixing in weak hydrochloric acid. Bank has described a process for the production of positives in platinum plus silver, as follows:—Thick Rives paper is painted with a solution of 20 grms. of ammonio-ferric oxalate and 5 c.c. of 2 per cent. potassium platinoous chloride in 100 c.c. of water. When dry, it is exposed under a negative and developed in silver nitrate, 1 gm.; citric acid, 1; ammonio-ferric citrate, 2.5; oxalic acid, 0.5; 4 per cent. potassium bichromate, 10 drops; water, 250 c.c. After washing, it is fixed in ammonia, 4 grms.; sodium citrate, 4 grms.; water, 200 c.c. The prints can be finally toned in a platinum bath if desired.

Arnold and Troost have introduced a paper giving a permanent brown image on a white ground which only requires water to finish it. 80 to 100 grms. of ammonio-ferric citrate, 12 to 20 of silver nitrate, 15 to 20 of tartaric acid, and (in another portion) 10 to 15 grms. of gelatin are dissolved in water, and the whole is made up to 1 litre. Paper is coated and dried as usual. Valenta finds that Merck's green ammonio-ferric citrate is preferable to the ordinary brown salt, for it is eight times more sensitive, the coating fluid keeps better, and the prepared paper itself keeps quite as well. His formula is: (A.) green double citrate, 12.5 grms.; water, 50 c.c.; (B.) potassium ferrieyanide, 4.5 grms.; water, 50 c.c.

Fisch has worked out Litterheim's "negrotype" again. A solution of 25 parts of gum arabic, 1 of potassium bichromate, and 1 of alcohol in 100 of water is spread on paper, dried, and exposed under a negative for  $\frac{1}{2}$  to 4 minutes. The print is dipped in water to remove the unaltered portion of the coating, then dried, and a varnish of 5 parts of bleached shellac, 1 of Frankfort (vine) black, and 100 of alcohol, applied with a brush. Finally, it is washed in 2 per cent. sulphuric acid, which dissolves the rest of the bichromated gum, leaving behind the pigment that has settled on the exposed parts or shadows of the picture.

For the intensification of carbon transparencies, Burton makes use of a 0.5 per cent. solution of silver nitrate, followed by a pyro-silver intensifier. A permanent warm brown tone is thus produced.

In the domain of collotype, Classen claims the application of a substratum of rosin soap to the plate before coating with the gelatin solution, thus obtaining a specially strong film capable of yielding an unusually large number of impressions. The chief advance in this direction is in the employment of aluminium to replace the glass supports. The use of the metal not only removes all danger of breakage, but makes the process easier to work in a bad or artificial light, as the condition of the film when in the press can be more readily seen against the white metallic background. Albert cleans the aluminium plates when new by rubbing them with 1:3 ammonia and drying them with a cloth. Used plates are freed from gelatin by immersion in 1:30 sulphuric acid and then cleaned as before. During the drying process the plates carrying the sensitive film should be supported horizontally on glass, and the exposure to light should not be carried so far as is necessary with glass supports. While being printed from, they are moistened ("etched") with glycerin and water only; but if the high lights take the ink at all, a little ammonia or preferably acid, may be added to the "etching" liquid.

Moses has patented an etching process for gelatin plates, which is particularly suited for plans, &c. A gelatin film is cemented to a ground-glass support by means of some adhesive insoluble in water. A ground, consisting of wax, asphaltum, mastic, and turpentine is next applied, and after drying, the design is drawn with the needle. The plate is then brushed over with a dark water-colour (e.g., Indian ink) rubbed down in a bichromate solution, and the glass side is exposed to light so as to render the gelatin insoluble where the ground has been perforated. The face is washed with a damp sponge, the ground removed by turpentine, and the whole treated with water containing glycerin, ammonia, and potassium nitrate, in order to swell the protected portions of the film, and to leave the lines

sunk below the surface. It can then be printed from as if it were an ordinary collotype plate.

For producing negatives suitable for photo-lithography, very slow grainless plates are requisite. These may be obtained from bromide plates of commerce by treating them with a 0.1 per cent. solution of bichromate before use. As an etching ground for zinc plates Pope recommends a mixture of asphaltum, 2 parts; rosin, 2 parts; and dragon's-blood, 1 part. This is dusted on, and finally melted as usual. In the preparation of relief blocks by the gelatin process, Vallot prefers to employ "meta-gelatin," which he makes by boiling 500 grms. of glue in 800 c.c. of water and 125 c.c. of ammonia for an hour, the amount of liquid evaporated being constantly replaced. To coat copper plates he uses 10 grms. of meta-gelatin, 3 of ammonium bichromate, and 100 c.c. of water; or 5 grms. of meta-gelatin, 50 of albumin, 3 of bichromate, and 50 c.c. of water. The latter formula allows of a stronger heating of the plate, but with the former the temperature must not exceed 334° C. Steel plates may be etched by placing them in contact with zinc in a mixture of the nitrates of silver and mercury, prepared by dissolving 30 grms. of silver in 100 of nitric acid, and 30 grms. of mercury in 150 c.c. of the same, adding 150 c.c. of water to each, then mixing the two together, and diluting to a convenient strength.

In working the three-colour process, Elsdon prepares colour screens in the subjoined manner:—For violet, strong solution of copper chloride, 7 c.c.; water, 17 c.c.; filtered and mixed with methyl violet B (concentrated solution), 3 c.c.; magenta S (ditto), 5 c.c. For orange-red, strong cobalt chloride, 15 c.c.; water, 35; 5 per cent. ammonium bichromate, 25; ammonia, 2–3 c.c., filtered. For green, a solution of nickel sulphate. These are placed in troughs with strictly parallel sides of about  $\frac{1}{2}$ -inch diameter.

## XXII.—EXPLOSIVES, MATCHES, Etc.

### PATENTS.

*Explosives [Ammonium Nitrate], Impts. in the Manufacture of.* G. G. André, Glenlean, Argyllshire; and C. H. Curtis, London. Eng. Pat. 11,842, June 1, 1896.

A SAFETY, or flameless, explosive consisting of ammonium nitrate, wood meal, and starch, or a certain proportion of potassium nitrate may be substituted for part of the ammonium nitrate. The following proportions are given: (a) wood meal, 4 per cent.; starch, 3.5 per cent.; ammonium nitrate, 92.5 per cent.; (b) wood meal, 4 per cent.; starch, 3.5 per cent.; ammonium nitrate, 90 per cent.; potassium nitrate, 2.5 per cent.—R. B. P.

*Explosives [Ammonium Nitrate], Improved Manufacture of.* G. Beneké, Southport, Lancashire. Eng. Pat. 13,922, June 24, 1896.

IN order to ensure the more thorough detonation of explosives compounded of ammonium or another inorganic nitrate and resins, the addition of bichromate of potassium, sodium, or ammonium, but preferably the potassium salt, is claimed. The necessity of a thoroughly even and intimate mixture of the ingredients is pointed out. The process of manufacture is briefly described, and the following given as the composition: ammonium nitrate, 92½ parts; resin, 5 parts; and potassium bichromate, 2½ parts.—R. B. P.

*Explosives [Smokeless Powder], Impts. in.* A. F. Hargreaves, Roslin, Scotland. Eng. Pat. 15,351, July 10, 1896.

SKAINS, or hanks, of cotton thread are nitrated, and then thoroughly washed and boiled until stable.

Whilst still moist, a suitable number of threads are twisted into a rope, which is then passed through a hot

water-bath in which any, or all, of the following substances have been dissolved:—Nitrates of barium, potassium, ammonium, and sodium, and a little starch or gum.

After passing through the bath, the "rope" is allowed to cool, and is then squeezed through rollers to remove excess of the solution. A number, preferably three, of these ropes are twisted together to form a still larger one, which, whilst still moist, is passed through a bath of acetone, or acetic ether, diluted with ether-alcohol, ether, benzene, or naphtha. Preferably, the bath consists of 1 part of acetone to 3 parts of benzene.

This stiffens the rope without destroying its fibrous nature, and causes the individual strands to adhere. Whilst still wet and in an unflammable state, the "rope" is cut into suitable lengths, which, after drying, constitute powder pellets.—R. B. P.

**Explosives [Smokeless Powder], Impts. in the Manufacture of.** F. W. Jones, Warwick, Herts. Eng. Pat. 1151, Jan. 15, 1897.

This invention aims at regulating the densities and rates of combustion of smokeless powders, particularly that kind of which nitro-cellulose gelatinised by a suitable solvent, is a main ingredient.

The first process consists in treating the granulated powder in a "swelling-bath," in which it is soaked in an aqueous or alcoholic solution of a solvent for nitro-cellulose, such as ether, acetone, ketones, and acetic ethers of the paraffins, for one or more days, either with or without agitation and the application of heat.

The solvent is then extracted by washing or by passing through steam, &c. This bath causes the powder to swell, the increase in bulk being greater, the greater the strength of the solution, the higher the temperature, or the longer the action is continued.

The powder, when freed from the solvent, is then dried for use.

In the case of powders in which one, or more, of the solid ingredients melts below the temperature of boiling water, and, when melted, has a solvent action on the base, such as the di- or tri-nitro derivatives of benzene, toluene, &c. the grains are kept in a bath of water at a temperature above the melting point of the above-mentioned ingredient for one or more hours (they may or may not have been previously treated in the swelling-bath). The effect of this treatment is to make the rate of combustion vary at different points in each grain, so that "the burning surfaces increase as the combustion progresses," thus enabling low initial pressures to be obtained. The following are given as three general compositions between the limits of which, powders for every kind of firearm can be made by these processes:—

1st. Nitro-cellulose, 100 per cent. to 75 per cent.

Slowing material, such as the di- and tri-nitro-benzene, toluene, and xylene, 0 per cent. to 25 per cent.

2nd. Nitro-cellulose, 90 per cent. to 60 per cent.; nitro-glycerin, 10 per cent. to 40 per cent.

3rd. Nitro-cellulose, 90 per cent. to 50 per cent.; nitro-glycerin, 10 per cent. to 25 per cent.; slowing material as in 1st, 0 per cent. to 25 per cent.—R. B. P.

## XXIII.—ANALYTICAL CHEMISTRY.

### INORGANIC CHEMISTRY.—QUALITATIVE.

**Carbonic Oxide, A Reaction of.** A. Mermet. *Comptes Rend.* 1897, 124, 621—624.

CARBONIC oxide was found to decolorise weak potassium permanganate solution acidified with nitric acid. The decoloration was hastened by silver nitrate. For the detection of 0.02 per cent. and upwards of carbonic oxide in air, two solutions (A. and B.) were prepared. A. was made by dissolving 2—3 grms. of silver nitrate in a litre of distilled water; B. by boiling a litre of water with a few drops of pure nitric acid and adding permanganate until the colour persists—indicating the destruction of organic matter—and then, after cooling, adding 1 gram. of permanganate crystals and 50 c.c. of nitric acid. The reagent was prepared

freshly, as required for use, by taking 20 c.c. of A., 1 c.c. of B., and 1 c.c. of nitric acid, and making up to 50 c.c. with water deprived of organic matter. 25 c.c. of this reagent was added to the suspected air collected by displacement of water in a stoppered flask; after standing for 24 hours screened from strong light, decolorisation was found to have ensued if carbonic oxide was present. A blank experiment was made simultaneously with good air. The decolorisation took place more rapidly the greater the amount of carbonic oxide. Air collected near an anthracite stove, and near a chimney subject to down draught, were found to be contaminated therewith.

Boussingault had previously found carbonic oxide accompanying the oxygen given off in daylight by plants. The author failed to detect it in the air of a greenhouse. It seemed possible that the quantities of carbonic oxide continually cast into the air might be partially oxidised to oxalic acid, and, to test this supposition, rain water was collected in an open field, concentrated, and examined. Traces of calcium oxalate were found. This matter is being further investigated.—J. A. B.

**Telluride Gold Ores.** R. Pearce. *Eng. and Mining J.*, April 17, 1897, 376.

FOR the detection of tellurium, when present in an un-oxidised form, as a telluride, in gold-bearing ores, a sample of the fine pulp is treated with strong nitric acid in a porcelain dish and heat applied until the material is perfectly oxidised. Strong sulphuric acid is then added, and heat applied until the excess of nitric acid is expelled, or until copious fumes of sulphuric acid are evolved. When cold, hydrochloric acid and water are added in about equal proportions, the solution is filtered and treated with stannous chloride precisely as in the case of oxidised tellurium ores, when a carmine tint is produced.

The production of the coloration by gently heating a minute fragment of the mineral with a drop of concentrated sulphuric acid is of little or no value, as the other minerals commonly associated with tellurium in gold-bearing ores, interfere with or conceal this reaction.—A. S.

### INORGANIC CHEMISTRY.— QUANTITATIVE.

**Potash, Soluble; Estimation of.** A. Mercier. *Bull. Assoc. Belge des Chimistes* 10, [11], 403—405.

IN place of the sodium formate employed in the old method of Correnwinder and Contamine, for the reduction of potassium platinum chloride, the author proposes to use mercurous chloride, with which the reduction commences at 60° C., and is complete at boiling temperature.

5 or 10 grms. of substance, finely ground under water, are digested cold for one hour in a 500 c.c. flask filled up to the mark with water, 25 c.c. of the clear liquid being then evaporated to dryness on the water-bath with 1 c.c. of hydrochloric acid and heated gently to drive off any ammonium salts and organic matter. The residue is taken up with water acidified with hydrochloric acid, filtered if necessary, and then evaporated to syrup with 10 c.c. of a 10 per cent solution of  $\text{PtCl}_4$ . When cold the precipitate is extracted with 50 c.c. of 85° alcohol + 5 c.c. of ether and washed with the same liquid until all the  $\text{PtCl}_4$  is removed, the remainder being dissolved in boiling water and the platinum precipitated as a heavy grey powder by the gradual addition of about 2 grms. of  $\text{HgCl}_2$  at boiling temperature, 1 or 2 c.c. of hydrochloric acid being added after the precipitate is settled, and the whole again heated to boiling point. When somewhat cooled the platinum is filtered off, washed with boiling water until free from chlorine, and calcined without drying the filter, the weight of metal multiplied by 0.4835 giving the amount of potassium oxide present in the substance in the soluble form.—C. S.

**Steel, Hardening-Carbon and Carbide-Carbon in; Determination of.** H. Jüptner v. Jonstorff. *Iron and Steel Inst.* May 1897; *Ironmonger* 1897, 79, 351—356.

HARDENING carbon has not hitherto been determined directly, but has been estimated (when necessary) by

deducting graphitic and graphitic temper carbon, and the ordinary carbide carbon from the total carbon, thus accumulating all the errors of the whole process in this one determination. The author has now investigated the colorimetric and gravimetric tests for carbon in steel and publishes in detail the results of his experiments. To determine the hardening- and carbide-carbon contents in steel he proceeds as follows:—0.2 gram. of the steel is treated with 10 c.c. of dilute nitric acid in the cold (2 vols. of concentrated acid mixed with 3 vols. of water), the vessel being allowed to stand in cold water. The solution is well and repeatedly shaken, and when no further evolution of gas is observed, it is well mixed and filtered through a dry filter without subsequent washing. The filter should first be hardened with nitric acid. 2 c.c. of the filtrate are used for the determination of the hardening carbon by direct colorimetric comparison with the ordinary colour standards. In this way (working in the cold) the comparison is accurate, but when the hardening carbon is less than 0.15 per cent. the colour of the solution is somewhat greenish and the results appear to be a little too low. The error may be rectified by multiplying by 1.3 the results obtained, when the solution is at all greenish. Another 2 c.c. of the filtrate are set aside. Meanwhile 0.04 gram. of the steel is weighed, treated with the dilute nitric acid, and transferred to a water-bath at 80° C., simultaneously with the 2 c.c. of hardening carbon test that had been placed aside. When complete solution is effected, both series of solutions are compared with the same standard, and from the compared volume of the solution of the total carbon, is subtracted the compared volume of the hardening-carbon solution which had been heated to 80° C. The difference gives the volume corresponding to the carbide carbon, from which the percentage contents can be readily calculated. The author uses unalterable standards made by mixing slightly acidulated solutions of  $\text{Fe}_2\text{Cl}_6$  and  $\text{CoCl}_2$ .

—W. G. M.

*Copper, Determination of, as Sub-sulphide.* R. Wegscheider. *Monatsh. f. Chem.* **18**, 44–47.

A REPLY to criticisms of Murmann's on a former paper of the author's (this Journal, 1894, 67, and 1897, 359). Murmann quotes the author as saying that the sub-sulphide method always gives figures too low by about 0.3 per cent. The author points out that his results were sometimes above, sometimes below the truth, and remarks that his work was performed on such small quantities that the manipulative losses, even with careful work, would always account for the low results. The same losses, on the amounts with which Murmann worked, would not have meant more than 0.1 per cent.

Murmann again quotes the author as directing that the crucible should be heated merely with the tip of the Bunsen flame; the real directions were to heat to dull redness, and the author pointed out that a rise of temperature above this would do no appreciable injury if not too long continued, for the reduction of the sub-sulphide by hydrogen is a very slow process. Murmann, lastly, makes the author say that the cause of too high figures when the ignition of the cupric sulphide is carried out in hydrogen sulphide, is *merely* that the cupric sulphide is then not completely decomposed, and points out that under these circumstances it is in part formed from the cuprous sulphide and hydrogen sulphide. The word, "merely," which alters the sense of the statement, was not in the author's paper. The decomposition of cupric sulphide in a stream of hydrogen sulphide is so rapid that its incompleteness is only to be accounted for by the existence of an inverse action and the attainment of equilibrium between the two; but the author did not think it necessary in an analytical paper to draw attention to this, and contented himself with mentioning the ultimate result. J. T. D.

*Acetylene as Quantitative Reagent.* [Estimation and Separation of Copper.] H. G. Soderbaum. *Ber.* **30**, 902–904.

It was shown recently (*Ber.* **30**, 760–814) that acetylene precipitates the metal completely from an ammoniacal copper solution as black cupric acetylide, and the mother-

liquor, after acidulating, does not give the copper reaction with potassium ferrocyanide. For analysis, the salt is dissolved in 100 to 200 times its weight of water, a few c.c. of ammonia are added, the solution is then warmed on the water-bath, and acetylene is passed through until the solution is saturated. The estimation is carried out preferably in an Erlenmeyer flask, and, if closed, the precipitate may be left an indefinite time without undergoing any change. On standing in an open vessel, however, a part of the copper again passes into solution. After filtering and washing the acetylide, it is digested for half an hour with hot dilute nitric acid, filtered from a carbonaceous residue, the filtrate evaporated to dryness and converted by careful heating into cupric oxide, which is then weighed together with the ashed filter-paper. The method is an accurate one; 0.4775 gram. of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  containing 0.1214 gram. = 25.42 per cent. of Cu, gave 0.1516 gram. of  $\text{CuO}$  = 0.1211 gram. = 25.35 per cent. of Cu. The presence of alkali salts does not affect the precipitation, although an excess of ammonium salts does. The filtrate from the acetylide can be utilised for determining the acid, thus: 0.5105 gram. of  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  gave 0.8565 gram. of  $\text{AgCl}$  = 41.5 per cent. (calculated 41.6 per cent.). The method has also been employed for separating metals, and in the case of a mixture of copper and zinc, accurate results have been obtained, care being taken to have sulphurous acid present, when the copper is precipitated at first as a brownish-red precipitate, which turns black, and contains Cu : C = about 2:3. The zinc is determined in the filtrate either gravimetrically or volumetrically.—T.A. L.

#### ORGANIC CHEMISTRY.—QUALITATIVE.

*Benzene, A Means of Distinguishing from Petroleum Spirit.* A. Gawalowski. *Chem. Zeit. Rep.* 1897, **21**, 100.

Picric acid easily dissolves in benzene with an intense yellow colour, whilst in petroleum spirit it is only slightly soluble with a nearly colourless solution. If an equal volume of petroleum spirit be added to a concentrated solution of picric acid in benzene, a crystalline precipitate of picric acid separates out.—A. S.

*Nitramines and Nitrosamines [Liebermann's Reaction, &c.], Characterisation of Aromatic.* J. Pionow. *Ber.* **30**, 833–843.

WITH a view of distinguishing between aromatic nitramines and nitrosamines, the author quotes certain reactions for this purpose, some of which can even be employed for separations, but no absolutely general method has been obtained. He employs principally Liebermann's nitroso reaction, for which purpose the substance is dissolved in phenol, two or three drops of concentrated sulphuric acid added, and the mixture is warmed for 5–10 seconds on the water-bath. Under these conditions, toluenediazoo acid ( $\text{C}_6\text{H}_4 \cdot \text{CH}_3 \cdot \text{NHO}_2$ ), trinitrotolyl- and trinitrophenylmethylnitramine do not give the nitroso reaction, although the latter gives a fine red coloration, but this is probably due to the action of the potash. Tolylmethyl nitramine gives the nitroso reaction in the cold, but the coloration has a greenish shade and is weak. Under all conditions, *p*-nitrophenylnitramine and its methyl ether give bluish-green colorations, whilst the same is the case with *o*-nitrotolylmethylnitramine in the cold, and with *m*-nitrotolylmethylnitramine and its methyl ether on warming. These two latter and *o*-nitrotolylmethylnitramine give dirty green to olive-green colorations, whilst, on warming, *o*-nitrotolylmethylnitramine and its methyl ether give greyish-blue, or, on longer heating, violet-blue shades. Tetranitrodimethyldinitramidodiphenylmethane requires to be warmed with phenol in order to dissolve it, and, according to the time of heating, gives bluish-green to pure blue colorations. The author concludes from these results that it would be possible in other cases to distinguish by means of this reaction between nitrosamines and purely aromatic nitramines, since the coloration, if any, obtained either in the cold or on heating, differs from the pure blue, given by the nitrosamines. It is further remarked that aromatic nitramines, under the action of mineral acids, are converted

into *p*- or *o*-nitrated anilines, whereas by the action of concentrated hydrochloric acid or of aniline hydrochloride on nitrosamines, the nitroso group is separated.—T. A. L.

[Brewing] *Saccharification of the Mash, Testing the*. J. Fuchs. Zeits. f. d. ges. Brauwesen, 20, [15], 203—204.

To prevent the iodine reaction from being masked by the brown and red colorations produced by dextrin, albuminoids, and particles of grains present in the mash goods, the following method is adopted in the laboratory of the Munich Scientific Station for Brewing:—

Small dry plates of gypsum, 1 to 2 cm. wide, 10 to 12 cm. long, and 0.4 to 0.8 cm. thick, are used, on to which is allowed to fall one drop of the wort or mash to be tested. The liquid is rapidly absorbed, leaving the non-liquefied portions on the surface of the plate, so that if a little iodine solution be applied to the same spot, a blue coloration will be produced so long as any of the starch remains unconverted. The iodine seems to be decolorised on absorption by the gypsum, and thus the end point of conversion is more sharply defined than when the test is performed in tubes or on a porcelain plate. Moreover, the various tests for each mash can be made on the one slab, which, the intervals between each test being inscribed thereon, can be kept as a permanent record.—C. S.

*Colouring of Wines, Distinguishing Coal-Tar Colours from Caramel*. A. d'Aguiar and W. da Silva. Bull. Soc. Chim. 1897, 17, 443—449.

It has been stated by Malaghaës (Comptes Rend. 123, 896; this Journal, 1897, 156) that it is not possible, by the tests commonly in use, to distinguish caramel from certain coal-tar colours when used for the purpose of colouring white wines and brandies. The authors have therefore made experiments in this respect with a number of yellow and brown coal-tar colouring matters. On extraction with amyl alcohol, the extract is less coloured in the case of caramel than in that of any coal-tar colour, except Naphthol Yellow S, and the latter colour is readily distinguished from caramel by dyeing silk threads in the solutions. When the amyl alcohol extracts are evaporated to dryness and treated with sulphuric acid, caramel yields a brownish-black colour, differing from all the rest. With other tests the authors obtain equally distinctive indications, and they conclude that the present methods of testing are entirely satisfactory.—R. B. B.

*Lavender Oil, Detection of Adulteration*. Schimmel's Rep., April 1897, 24.

An ingenious fraud has lately been detected, demonstrating that certain unscrupulous dealers keep themselves well informed in the advance of analytical processes for the valuation of essential oils, and endeavour to meet the tests by more than ordinary methods. Two samples of lavender oil were sent for valuation, which gave the following data:—

No.	Specific Gravity.	Optical Rotation.	Per Cent. of Ester.
1	0.900	6° 53'	48.5
2	0.905	3° 50'	47.5

The facts that the specific gravity of these oils was abnormally high and that during the process of saponification a solid body, never before observed, separated from the alcoholic potash solution, aroused suspicion. A larger quantity was therefore saponified with aqueous potash solution, since ethyl or methyl esters would escape detection when alcoholic potash is used. On separating the alkaline solution and distilling, several c.c. of ethylic alcohol were obtained. In the residue, the presence of an organic acid was detected; this was isolated, purified, and proved to be succinic acid. Since pure lavender oil does not contain ethyl succinate, it is evident that this ester had been added for the purpose of giving a fictitious value to the oil, as shown by its ester number. In the present instance, about 8 per cent. of ethyl succinate had been added, which would

require the same amount of potash for its saponification as about 18 per cent. of linalyl acetate. In order to rapidly detect the presence of the esters of succinic, oxalic, or corresponding acids in lavender oil, the following simple test is available:—About 2 grms. of the oil are saponified, and the portion insoluble in water washed out with ether, the aqueous residue is neutralised with acid and diluted up to 50 c.c.; to this, 10 c.c. of cold saturated barium chloride solution are added, the liquid warmed on the water-bath for two hours, and then cooled. The formation of any crystalline precipitate is indicative of adulteration, since the barium salts of acetic and butyric acids, the normal organic acids of lavender oil, are soluble.—J. O. B.

*Star Anise Oil [Testing for Kerosene]*. Schimmel's Rep., April 1897, 37.

ALTHOUGH much oil, which had an abnormally low congealing point, has been met with, the admixture of kerosene has not been discovered. To test the question, 30 kilos. of abnormal oil, congealing at 10° 25 and 10° C., were fractionated, but no kerosene was found in the first fraction of 300 c.c. It is possible that the abnormally low congealing point may be due to a large proportion of methylcavicol present. The experimental admixture of kerosene with star anise oil shows that its presence does not greatly modify the congealing point, but markedly lowers the specific gravity and affects the solubility in alcohol. The gravity of the pure oil should lie between 0.980 and 0.990 at 15° C., and it should give a perfectly clear solution with 3 parts of 90 per cent. alcohol.—J. O. B.

#### ORGANIC CHEMISTRY.—QUANTITATIVE.

*Alizarin, Analytical Methods employed in the Manufacture of*. A. G. Perkin. J. Soc. Dyers and Colourists, 1897, 81—87.

THE Meister, Lucius, and Brünig modification of Luck's method, of 1876, is still universally employed. (See Lunge's Coal-Tar and Ammonia, 1887, 318—327.)

The nature of the impurities accompanying the anthraquinone, which require the use of fuming sulphuric acid for their removal, has not yet been properly explained. They are said to consist of quinones, which though unattacked by chromic acid like anthraquinone, differ therefrom in yielding sulphonic acids at 100°. Anthraquinone before treatment with sulphuric acid usually contains chromium compounds requiring the use of fuming sulphuric acid for their decomposition.

Bassett's addition to the present test, based upon a second oxidation with a mixture of chromic and nitric acids (this Journal, 1896, 385) should give a very pure product. By this means all methylanthraquinone and the chromium salts of impurities, are destroyed.

Commercial anthracenes are divided into two classes, known as A and B quality. The nature of the impurities present in the latter is not thoroughly understood, though of these,  $\beta$ -methylanthracene is frequently one. In the usual process this yields first its quinone and finally methylalazarins, which dye shades of a duller character and less fast than the true alizarins.

Paraffin, if present in anthracene, may be detected by heating the sample with sulphuric acid at 100°.

For the analysis of crude anthraquinone two distinct tests are necessary. (1.) Determination of the anthraquinone it is capable of yielding. (2.) Determination of the anthraquinone present in the crude product. The former operation is simply an anthracene test by Luck's method, whilst in carrying out the second test, 10 grms. of the finely powdered sample are treated with 10 to 15 grms. of sulphuric acid at 100° for one hour. The mass is then boiled out in water and the anthraquinone filtered, washed, dried, and weighed. To ascertain its purity, 1 gm. is treated with 10 grms. of sulphuric acid containing 10 per cent. of sulphuric anhydride at 100°, for one hour. It is then placed in a damp atmosphere for 12 hours and allowed to crystallise. After the addition of water the crystals are collected, washed with water, dilute alkali, again with water, dried and weighed. From the

difference between the result of this analysis and that of Luck's method, the percentage of unoxidised anthracene can be easily calculated.

The method employed for the analysis of purified anthraquinone, consists in heating 1 grm. with 10 grms. of sulphuric acid containing 10 per cent. of sulphuric anhydride, the course of procedure being identical with the second portion of the anthracene test. The grey or green tinge of anthraquinone purified with sulphuric acid, is due to the presence of a dark-coloured amorphous product, which is insoluble in the usual solvents and contains nitrogen, originating possibly from the carbazol or other nitrogenous impurities existing in crude anthracene. Methylantraquinone being moderately soluble in boiling dilute sulphuric acid, especially if this contains other sulphonic acids in solution, a purer anthraquinone is obtained by filtering the purified product from the acid solution of sulphonated hydrocarbons at an elevated temperature.

For the final purification of anthraquinone it is either re-purified with sulphuric acid at 100°, or sublimed by means of superheated steam, or recrystallised from some suitable solvent. The estimation of pure anthraquinone is carried out in the same way as that employed with the purified product. Frequently, however, its valuation in this manner is accompanied by a second determination, in which the full anthracene test is used.

*Sodium Anthraquinone-monosulphonate* is produced on a large scale in an almost chemically pure condition, and no analysis is required beyond a determination of the moisture present. The filtrate and washings from this salt consist chiefly of a mixture of the two disulphonic acids. If neutralised and converted into colour, no further valuation is required, for knowing the weight of anthraquinone originally employed in the sulphonation, and also the anthraquinone value of the sodium mono salt and unattacked anthraquinone, this value can be at once determined by difference. The anthraquinone unattacked during the sulphonating operation, is mostly weighed and sampled in the wet condition, the amount of moisture being then determined. For its analysis 1 grm. of the dried sample is dissolved in glacial acetic acid and the solution treated with chromic acid (one-half the usual quantity) as in the first portion of the anthracene test.

*Sodium Anthraquinone-disulphonates*.—If the resulting solution of the  $\alpha$ - and  $\beta$ -disulphonic acids be at once neutralised and converted into colour, no analysis is necessary, for as a rule the whole of the anthraquinone is sulphonated. If, however, a separation of the acids be desired, one of the resulting sulphonates must be examined. For its analysis, the amount of moisture is first determined and the dried residue subsequently incinerated with the aid of ammonium nitrate or sulphuric acid. The loss by ignition multiplied by  $1.526 \times 100$  and divided by the weight of dry substance, gives the percentage of the pure salt in the dry substance.

In the process of fusing the sodium salts of anthraquinone-sulphonic acids, samples of the melt are drawn off at stated periods, weighed portions being dissolved in a measured quantity of boiling water and neutralised with acid. When considered essential, the precipitated colour can be roughly washed, dried, and weighed, for the weight of the main melt being approximately known, a fair indication of the progress of the reaction can be thus obtained. With experience, however, this can be judged from the appearance of the precipitate, and the colour of the filtrate in an acid or alkaline condition, taking into consideration also the length of time that the operation has been in progress. Special tests can be employed for the detection of methylhydroxyanthraquinone and anthra- or iso-anthraflavic acids in the melts.

For the analysis of alizarin pastes as obtained from filter presses, the percentage of moisture is determined by evaporating a weighed sample in a flat platinum dish at 100°. After weighing, the inorganic matter present is determined by incineration. Usually the ash, which should not exceed 0.2 per cent. in a 20 per cent. paste, consists of either sodium or calcium salts, but sometimes lead and iron are also present, though contamination of alizarin with iron should be carefully avoided when dyeing bright shades. The tinctorial properties of the paste are then

compared with those yielded by a standard sample of known strength and shade. In this operation a special five-striped cotton cloth is best employed, the mordants on which, consist of strong and weak aluminium and iron salts and a mixture of the two respectively. Of this, 10-in. lengths are most suitable. The dye vessels, preferably of glass, and of about 600 c.c. capacity, are arranged in rows in a long copper water-bath heated with gas. A portion (5 grms.) of the 20 per cent. paste under examination is suspended in a litre of water, and 50–70 c.c. of this, together with 4 c.c. of a 1 per cent. solution of calcium acetate are added to 500 c.c. of water, in the dye vessel. The temperature is gradually raised to 80° during one hour, the heat being maintained at that temperature for half an hour. After washing in cold water, the fents are well beaten with a wooden mallet and again rinsed, the treatment being continued until the loosely-adhering particles of alizarin are almost entirely removed. This is followed by two soaping operations, each lasting one hour, the first at 60° and the second at 80°, conducted in a large tinned copper vessel, which contains for each fent a solution of 0.5 grm. of curd soap in a litre of water. The patterns after washing are dried at the ordinary temperature. Swatches of Turkey-red cloth are very frequently dyed, and these, after the ordinary soaping, are heated under pressure with soap solution, to which a trace of stannous chloride has been added to confer on the tints a more brilliant appearance. The author has, in a previous communication (this Journal, 1894, 496), described a method depending on the fact, that the colours of the alkaline solutions of the alizarins are comparable to the dyed shades they produce.

*m-Hydroxyanthraquinone* may be detected, by treating a hot alkaline solution with baryta water and filtering the precipitate. A red coloured filtrate is obtained, which on acidification deposits a yellow precipitate.

*Anthra- and Iso-anthraflavic Acids*.—To a sample of the paste suspended in boiling water barium hydrate is added and the barium lake filtered off. A red coloured filtrate giving a yellow precipitate on neutralisation indicates the presence of these substances.—D. B.

#### *Silk-Weighting, Estimation of.* —Leipziger Färber u. Zengdrucker Zeit. 46, [6], 259–260.

For the purpose of estimating the substances employed for the weighting of silk, either the foreign substances are first removed by means of solvents, or the amount of nitrogen is determined and that of silk present calculated therefrom. The latter method gives good results, but is not always easy of execution, as the presence of gelatin or Prussian blue would interfere with the results.

*Black Silk* is first dried at 110° C., and is then alternately boiled with sodium hydrate solution (2 parts of soda to 100 parts of water) and dilute hydrochloric acid (1 part of acid to 4 parts of water), the silk being well washed after each boiling, and dried at 110° C. The loss of weight gives the amount of weighting. Any residual metallic substances that may not have been removed by the foregoing process may be determined by incinerating the extracted silk and weighing the ash. The alkaline extract may be tested for Prussian blue with ferrous sulphate by first acidifying the solution. The acid solution would contain any iron or tin salts which are tested for by well-known methods.

The best method, however, is to ascertain the actual quantity of silk fibre by Kjeldahl's process, any gelatin or Prussian blue being first removed by boiling the sample first with ammonium carbonate, then in dilute acid, and finally washing well and drying. Pure silk contains 17.6 per cent. of nitrogen.

*White or Light Coloured Silk*.—The sample is boiled in water, and sugar is tested for by means of Fehling's solution. Magnesium salts or sodium sulphate are tested for in the same solution. Tin, if present, is best looked for in the ash; and for tannin, the silk is boiled in very weak hydrochloric acid and the solution tested with gelatin and ferrous sulphate. When the ash is not completely soluble in hydrochloric acid, barium sulphate or a silicate of the alkaline earths may be present. In dark-coloured silks, chromium may also be present, which is found by fusing the ash with sodium nitrate, and then testing for chromic acid.—L. S.

*Fats, Note on Weighing out.* C. E. Cassal. Analyst, 1897, 22, 113.

In carrying out the Reichert process, it is essential that exactly 2.5 grms. of butter-fat should be operated upon to obtain comparative results. The author recommends the use of thin porcelain boats, open at one end, and having a small projecting handle at the other end (of shovel form). A number of these boats are ground to the same weight. When weighing out, one boat is counterpoised with another, and the fat may thus easily be weighed directly into the boat. The boat containing the fat is suspended in the neck of the distilling flask, and the fat washed down by heating the alcohol which has been placed in the flask for the process of saponification.—A. S.

*Hübl's Iodine Solution, Waller's Method of Improving.* R. Pelgry. Mitt. k. tech. Versuchsanst. zu Berlin, 14, [586], 316—320.

THE author confirms Waller's statement to the effect that the iodine numbers obtained by means of the modified solution of the latter (Waller adds 25 grms. of hydrochloric acid of sp. gr. 1.19 to every 500 c.c. of the iodine solution, Chem. Zeit. 1895, 1786, 1831) give results coinciding with the Hübl iodine values. The addition of hydrochloric acid as specified by Waller, renders the reagent more stable, so that even freshly prepared solutions may be used.—S. P. E.

*Fat in Oleakes, Estimation of, by Carbon Tetrachloride.* A. Bilteryst. Bull. Assoc. Belge des Chimistes, 10, [11], 406—410.

TEN grms. of substance are placed in the extractor, and heat applied for three hours, the solvent being then evaporated, and the fat weighed.

For the cold process, no extractor is required, 20 grms. of substance being shaken up in a flask with 100 c.c. of tetrachloride at intervals during 24 hours. 50 c.c. of the solution are then filtered off and evaporated, the residual fat representing the amount in 10 grms. of substance, except for the necessary correction due to the volume of the fat itself in the extract. This may be ascertained by redissolving the fat in 50 c.c. of tetrachloride and multiplying the weight of the fat by a fraction, the numerator of which is the new volume, and the denominator the 50 c.c. of solution evaporated.

The warm tetrachloride method is more expeditious than the ether method, and, at the same time, free from all risk of ignition of the solvent. Since the latter neither contains nor absorbs water, the oleake need not be dried at 100° C. In the cold method, no fragile or expensive apparatus is required.—C. S.

*Lard, Detection of Vegetable Fats in.* A. Forster and R. Riechelmann. Zeits. für offentl. Chem. 1897, 10; Pharm. Centralhalle, 1897, 38, 151.

THE authors detect the presence of vegetable fats in lard by identifying the crystalline form of phytosterin, which is a constant constituent of vegetable fats, but is never found in animal fats, nor in butter. The following method, which enables the examination to be completed in 2½ hours, is given for the isolation of this body. 50 grms. of the lard are boiled with two successive 75 c.c. of 95–96 per cent. alcohol under a reflux condenser for about five minutes each, with thorough agitation. The mixture is thoroughly cooled, and the alcoholic solution filtered. The filtrate is heated on the water-bath with 15 c.c. of 50 per cent. soda solution, until about three-fourths of the alcohol has evaporated. The residue is evaporated nearly to dryness, transferred to a separator, and shaken out with ether. The ethereal extract is distilled to dryness, and the residue again taken up with a small portion of ether and filtered; on its evaporation, the residue is recrystallised from 95 per cent. alcohol, and is then in a state of sufficient purity for microscopical examination. Phytosterin is distinguished by the formation of acicular crystals in stellate or aggregate groups, readily distinguished from the rhomboid tablets of animal cholesterol.—J. O. B.

*Cholesterol in Fats, Detection of.* A. Forster and R. Riechelmann. Zeits. für offentl. Chem. 3, 10; Analyst, 1897, 22, 131.

SALKOWSKY'S method (this Journal, 1888, 37) is said to require a considerable length of time and a comparatively large quantity of ether (500 c.c. for 10 grms. of fat); the separation of the fluids is said to be slow and often imperfect, and the saponification never to be complete. In the method of Kossel and Oehmüller, the separation of the soap is, it is said, slow and incomplete, and the ethereal solution yields, on cooling, a crystallisable oil admitting of yet further saponification.

The process recommended is that given in the preceding abstract—A. S.

*Glycerin, Estimation of Small Quantities of.* M. Nieloux. Bull. Soc. Chim. 1897, 17, 455—458.

THE author's process for the estimation of small quantities of alcohol by means of potassium bichromate in presence of sulphuric acid (this Journal, 1897, 473), has recently been proposed by Bordas and de Raczowski for the estimation of glycerin (Comptes Rend. 1896, 1071; this Journal, 1897, 167). Several corrections should, however, be made in the statements of these authors. No formic acid is produced in the reaction, since this substance would be at once oxidised to carbon dioxide and water. The equation should be—

From this it will be found that 7.456 grms. of potassium bichromate correspond to 1 gm. of glycerin. A solution should be made containing 19 grms. of bichromate per litre, and 2 c.c. of this solution corresponds to 5 c.c. of glycerin (1 gm. per litre). Where the amount of glycerin is between 1 and 2 grms. per litre, the bichromate solution should be twice the above strength. The end reaction is indicated by a change of colour from bluish-green to yellowish-green with  $\frac{1}{100}$ th c.c. of the bichromate solution, solutions of the required tints, before and after excess of bichromate is added, being prepared beforehand for comparison.—R. B. B.

*Glycerin, the Quantitative Estimation of.* F. Bullnheimer. Forsch. Ber. ü. Lebnsm. u. ihre Bez. z. Hyg., &c. 4, 12 --21 and 31—45; Chem. Centr.-Bl. 1897, [1], 522—523 and 773—774.

THE author gives the results of a series of experiments regarding the behaviour of glycerin towards metallic oxides, made with a view to quantitative estimation of the former.

*Solvent Power.*—Of the oxides that are known to be soluble in glycerin, those of lead, iron, and uranium were excluded on account of the instability of their solutions, thus leaving only the oxides of copper, bismuth, and antimony. When experimenting with alcoholic, alkaline copper oxide solution, the author met with a body which he considers is probably "copper-potassium glyceride," and this he is examining further. It forms minute, acicular crystals of a bright blue colour and silky lustre, gradually decomposed in the air and turning green; soluble in water and dilute alcohol, insoluble in absolute alcohol. Bismuth nitrate and antimony chloride behaved similarly towards glycerin. The solubility of basic bismuth hydrate ( $\text{Bi}_2\text{O}_3\text{H}$ ) depends on the degree of concentration of the alkaline glycerin solution, and is of no value for the quantitative estimation of glycerin.

*Reducing Power.*—Copper oxide and glycerin were heated together in a sealed tube to 150° C.; only a slight reduction took place. Ammoniacal silver oxide solution also gave unsatisfactory results, and it was necessary to use the oxide itself, to effect oxidation of the glycerin. Gold oxide in alkaline solution is reduced by heating with glycerin. A concentrated solution of glycerin, mixed with a few drops of such a liquid, gives, in the cold, a cherry-red colour, changing to violet on warming; on continued warming, the colour changes to a greyish-green, and metallic gold separates out. Freshly precipitated mercuric oxide undergoes no change on heating with glycerin alone, but in presence of strong bases, reduction to mercury

takes place. Mercuric iodide is reduced to metal more readily than mercuric chloride, by excess of glycerin in presence of caustic potash. Thallium trioxide is reduced in presence of alkali to monoxide, and the trichloride to monochloride; thallium monoxide is not altered. Lead dioxide has already been tried, without success, by Schumann for estimating glycerin. Bismuth pentoxide is reduced, in presence of alkali, to basic hydrate ( $\text{BiO}_2\text{H}$ ). Manganese dioxide and the basic oxides of manganese are not reduced in presence of alkali, but the acid-forming oxides give off oxygen. Ferric oxide, in presence of caustic potash, remains unchanged, but potassium ferricyanide is slowly reduced to ferrocyanide. Nickel sesquioxide is converted into the hydrate,  $\text{Ni}(\text{OH})_2$ , but the reduction is incomplete. Neither cobalt sesquioxide nor the double cyanide of cobalt and potassium are reduced by glycerin; towards cobaltous chloride, glycerin behaves like the sugars. Metallic palladium is precipitated from palladium oxide by potash and glycerin; palladium chloride, in presence of potash and ammonia, is not altered. Platinum chloride is reduced by alkaline glycerin solution, but the reaction is not so sensitive as the palladium, silver, and gold reactions. Ruthenium potassium chloride is not altered by alkaline glycerin, but rhodium chloride is reduced. The brown solution of osmium tetrachloride in potash becomes nearly colourless on boiling with glycerin, but no reduction to metal takes place. Iridium chloride, on heating with potash and glycerin, undergoes no apparent alteration.

Six oxides— $\text{Ag}_2\text{O}$ ,  $\text{Au}_2\text{O}_3$ ,  $\text{HgO}$ ,  $\text{Rh}_2\text{O}_3$ ,  $\text{PdO}$ , and  $\text{PtO}_2$ —are reduced to metal by alkaline glycerin, the remainder only giving up either part of their oxygen or none at all.

**Quantitative Estimation of Glycerin by the Reduction of Metallic Oxides.**—Concordant results were obtained by the reduction of palladium oxide with alkaline glycerin, but as mono- and polyvalent alcohols, acetaldehyde, acetone, carbohydrates, formic acid, &c. also effect the reduction, the method is practically of no use. The reduction of mercuric iodide by alkaline glycerin gives valueless results. The amounts of metallic silver obtained by the reduction of silver oxide correspond fairly well when like quantities of glycerin are used, but with varying quantities of glycerin, the results are not strictly proportional. According to Kiliani (*Annalen*, 205, 191), besides oxalic acid and carbon dioxide, formic acid and glycollic acid are obtained by treating glycerin with silver oxide, but the author states that as the oxidation products of glycerin are further oxidised by silver oxide, there can only result as final products of the reaction, formic acid, oxalic acid, and carbon dioxide. The silver oxide process is carried out in the following manner:—20 c.c. of glycerin solution, containing, at the most, 0.15 gm. of glycerin, are placed in an Erlenmeyer flask of 10 c.m. diameter at the bottom, with 4 grms. of  $\text{AgNO}_3$ , and after the latter has dissolved, 5 c.c. of 50 per cent. caustic soda are added, and the whole mixed by moderate shaking till a thick pulp forms. The flask is placed up to the neck in a vigorously-boiling water-bath for  $3\frac{1}{2}$  hours, and then diluted with 100 c.c. of water. The liquid is cooled and decanted, the precipitate washed once with water, and then treated, on the water-bath, with a solution of sodium bisulphate (30 grms. of concentrated  $\text{H}_2\text{SO}_4$  and 100 grms. of  $\text{Na}_2\text{SO}_4$  to the litre), till it appears bright grey. The liquid is then decanted off as far as possible, the precipitate washed twice with 25 c.c. of 10 per cent. ammonia, dried, ignited, and weighed. One molecule of glycerin, when operating with 0.15 gm. of glycerin, corresponds to 1,060—1,070 parts of silver; in round numbers, 1 part by weight of glycerin = 11 parts by weight of silver.

After criticising the numerous methods for the estimation of glycerin in fermented liquors, the author considers that of the German Imperial Commission of 1884 to be the best, and he recommends the examination of the separated glycerin by his silver process. Thus, he found that the amount of real glycerin in that separated from different wines was as follows:—White wine, 80.7 to 97.5 per cent.; red wine, 86.9 to 100.1 per cent.; and sweet wine, 66.8 to 75.4 per cent.—A. S.

*Chloroform, Analysis of.* A. Béhal and M. François.  
J. Pharm. Chim. 1897, 5, 417—424.

In certain respects commercial chloroform does not satisfy the tests of the Codex. It crystallises more or less on cooling to  $20^\circ$ — $40^\circ$  C., turns chromic acid green, and is coloured by crystallised magenta and dinitrosulphide of iron. The impurities to which these reactions are due, are water and alcohol, the former introduced with the alcohol added to render the chloroform less liable to decomposition.

The method adopted for the determination of the alcohol is a modification of that of Nieloux (this Journal, 1897, 473; see also Kuriloff, this Journal, 1897, 473). The bichromate solution contains 16.97 grms. per litre, 2 c.c. thus correspond to 0.01 c.c. of absolute alcohol. 5 c.c. of the dilute alcohol solution to be estimated are placed in a test tube surrounded by boiling water, 2 c.c. of sulphuric acid is added, and then the bichromate until the yellowish-green tint is reached. For the estimation of alcohol in chloroform, 10 c.c. of chloroform are shaken with 4 c.c. of sulphuric acid in a stoppered tube, provided with a tap at the lower end, the acid drawn off, and the process repeated with 4 c.c., and finally 2 c.c. of acid. The whole 10 c.c. of acid are placed in a small flask, 40 c.c. of water added, and 20 c.c. slowly distilled off, 5 c.c. of the distillate are now taken for the alcohol estimation. The test analyses quoted are satisfactory. Chloroform so deprived of alcohol and water should satisfy all the Codex tests.

The authors recommend that the Codex should recognise the addition of 5 or 10 c.c. of absolute alcohol to 1 litre of chloroform, and give the tests to which such a mixture should be subjected. The odour should be pleasant, as also that of the residue after evaporation, it should be neutral to litmus, should not precipitate or reduce silver nitrate, nor colour sulphuric acid or be coloured by boiling with solid potash. Also the chloroform deprived of alcohol by sulphuric acid, should entirely distil at  $60^\circ$ — $8^\circ$  C., the distillate should have the density of 1.500 at  $15^\circ$  ( $1.523$  at  $0^\circ$  C.), should not crystallise on cooling to  $40^\circ$ , and should not be coloured by contact with chromic acid or dinitrosulphide of iron. The magenta test is rejected as too delicate, the authors could not prepare chloroform which was not rapidly coloured in contact with air by this reagent.—A. C. W.

*Ethyl Alcohol and Glycerin, Determination of.* Nieloux.  
J. Pharm. Chim. 1897, 5, 424—427.

BORDAS and Raczkowski take a bichromate solution of 21 grms. in 1 litre, as compared with the 20 grms. given by Nieloux, 1 c.c. of each solution being said to correspond to 0.1 c.c. of absolute alcohol in 100 c.c. of the solution. The author now finds that, under the conditions he gave—addition of 4—5 c.c. of sulphuric acid, boiling for some seconds, end point a yellowish green—19 grms. per litre is more nearly correct. The method given by Béhal and François (see preceding abstract) gives accurate results under the conditions they observe.

In the determination of glycerin, solutions of 38 or 19 grms. per litre should be used, 1 c.c. corresponding to 5 c.c. of a solution of 1 or 0.5 gm. of glycerin per litre. 4 or 5 c.c. of strong sulphuric acid are used, the mixture is warmed for one minute, and after five minutes waiting the reaction is complete. The equation for the reaction is—

*Caoutchouc, Valuation of Raw and Manufactured.* R. Henriques. *Zeits. für öffentl. Chem.* 3, 37; *Analyst*, 1897, 22, 134.

**Raw Caoutchouc.**—This product contains water, inorganic substances (sand, stone, clay, &c.), organic impurities (leaves and twigs), added gum resins from other plants, and the so-called caoutchouc resin, distinguished from the true caoutchouc substance by its ready solubility in ethyl and methyl alcohol and in acetone. The method of analysis is as follows:—A weight of 50 to 100 grms. is macerated in water in a small roller apparatus—similar to the kneading and washing machine used in india-rubber works—by which

the mechanical impurities are removed. If a proper macerating apparatus is not available, the mechanical impurities may be eliminated by the aid of water and a pair of scissors. The resulting rubber is dried at 80° to 90° C., and weighed. The caoutchouc resin is then extracted by digesting 5 to 10 grms. of the washed and dried rubber for two to three hours with acetone, in a Soxhlet apparatus; the residue is quickly dried and weighed. The ash is also determined, and the percentage of true caoutchouc obtained by difference.

**Manufactured Rubber.**—The principal constituents are: 1. Added substances, such as lead oxide, heavy spar, gypsum, zinc oxide and carbonate, chalk, potash, magnesia and magnesium carbonate, golden antimony sulphide, ferric oxide, kieselguhr, asbestos, powdered glass, pumice stone, &c. 2. Caoutchouc resin, soluble in alkalis. 3. Caoutchouc substitute, asphalt, and gum resins. 4. Free sulphur. 5. Insoluble caoutchouc resin. 6. Combined sulphur, as vulcanite. 7. True caoutchouc substance. The rubber is analysed in the following manner:—5 grms. of the sample reduced to a fine powder by the aid of a sharp file, are boiled for three to four hours in a 3 to 4 per cent. alcoholic solution of caustic soda, which effects the solution of the free sulphur, resin, caoutchouc substitute, and the soluble caoutchouc resin, in addition to which, many organic constituents may be attacked and partly dissolved. The solution is filtered whilst still boiling, and the residue washed with boiling alcohol. If the presence of asphalt be suspected, the residue is treated with cold nitrobenzene; otherwise this operation may be omitted. The residue is then washed into a beaker, and boiled several times, first with water and then with hydrochloric acid, the washings being decanted through the same filter. The residue is then all brought on to the filter, washed with hot water, pressed, dried at 80° to 100° C., and weighed. The drying must not be continued longer than necessary, as the dry caoutchouc gradually takes up oxygen. The residue now contains the caoutchouc substance, the combined sulphur, insoluble inorganic substances, a very small quantity of the caoutchouc resin, and a little carbonaceous matter added for colouring purposes. If the ash and the sulphur be now determined, and their amounts deducted from the residue, the remainder will be the true caoutchouc substance.

—A. S.

**Marmé's Reagent, Limit of Sensibility of, to certain Alkaloids.** S. Vervén. *Ann. de Pharm.* 1897, **13**, 115; *Chem. Zeit.* Rep. 1897, **21**, 116.

THE reagent employed for the quantitative determination of its sensibility to the following alkaloids, consisted of 5 grms. of cadmium iodide and 10 grms. of potassium iodide in 100 c.c. of water. 5 c.c. of the aqueous solution of the alkaloid of known strength, rendered slightly acid with sulphuric acid, was added to 1 c.c. of the reagent and shaken; it produced a precipitate; the liquid was then diluted with water until the final dilution, with which only a slight precipitate was obtained, was in the following ratio for each alkaloid enumerated:—Atropine (Merck), 1:1600; cocaine hydrochloride (puriss. cryst.), 1:16,900; veratrine (Merck, puriss. cryst.), 1:5400; strychnine (cryst.), 1:19,200; brucine (cryst. puriss.), 1:14,600; quinine (cryst.), 1:32,300; cinchonine (cryst.), 1:18,400; aconitine (Merck, purum. cryst.), 1:1300. The following dilutions gave no precipitate, even on standing for a few minutes:—Atropine (Merck), 1:1900; cocaine hydrochloride (puriss. cryst.), 1:20,800; veratrine (Merck, puriss. cryst.), 1:8200; strychnine (cryst.), 1:32,000; brucine (cryst. puriss.), 1:18,200; quinine (cryst.), 1:37,700; cinchonine (cryst.), 1:21,600; aconitine (Merck, purum. cryst.), 1:27,400.—J. O. B.

**Phosphoric Acid in Wine, Simple Method for the Estimation of; especially in Sweet Wine.** W. Thörner and R. Uster. *Forsch. Ber. ü. Lebensm. u. ihre Bez. z. Hyg., &c.*, **4**, 55—58; *Chem. Centr.-Bl.* 1897, [1], 825—826.

25 c.c. of sweet wine (in the case of ordinary wine, 50—100 c.c. are taken and evaporated to 25 c.c.) are heated for some time with 10 c.c. of concentrated nitric acid (sp. gr. 1.35) in a covered beaker on the water-bath. A vigorous

evolution of gas takes place, and the liquid becomes bright yellow. The reaction is complete in 20 to 30 minutes. Ammonia is added till the liquid distinctly smells ammoniacal, and then 25 c.c. of ammonium citrate solution. The liquid becomes darker, but remains clear. The phosphoric acid is finally precipitated, with stirring, by 15 to 20 c.c. of magnesia mixture. The results obtained by this method are always a few thousandths per cent. less than by the method in which the wine is first evaporated and the residue calcined.—A. S.

**Chocolate, Detection of Earth Nuts [*Arachis hypogaea*]** in. A. Bilteryst. *Bull. Assoc. Belge des Chimistes*, **10**, [12], 447—452.

THE presence of arachis- or earth-nuts in chocolate may be detected microscopically by the large starch grains (with nucleus) visible in aqueous or glycerin preparations, and by the cells with decided internal markings discernible in chloral preparations.

In the chemical examination, 2 grms. of the chocolate are heated in a flask with 50 centigrams. of mercury, 20 c.c. of sulphuric acid, containing 15 per cent. of phosphorus pentoxide, and 10 grms. of acid potassium sulphate, slowly for 20 minutes, and then strongly until decolorisation occurs (in about half an hour). After cooling and taking up with 100 to 120 c.c. of water, the mixture is transferred to a 750—1,000 c.c. retort, where 100 c.c. of sodium hydroxide solution (500 grms. per litre), 20 c.c. of sodium sulphide solution (40 grms. per litre + 50 c.c. of above NaOH solution), and 2 grms. of zinc are added, and heated until 50 c.c. have distilled over. Ten minutes will suffice to drive off the ammonia, which is absorbed in 50 c.c. of decinormal sulphuric acid, the excess of which is then titrated with Congo red solution. To prevent the contents of the retort frothing over, 10 drops of paraffin oil are added before distilling.

The albuminoid matters determined by this process amounted to 9.1 per cent. in the case of pure chocolate; 28.18 per cent. in that of earth nuts; 17.57 per cent. in that of pure cocoa; 46.9 per cent. in that of earth-nut cake; 12.53 per cent. in that of chocolate + 10 per cent. of earth nuts, or 15.7 per cent. with 10 per cent. of earth-nut cake, and 21.18 in the case of cocoa + 10 per cent. of earth-nut cake. Foerster's modification of the Kjeldahl method may also be employed.

In estimating the fatty matter, the refractometer index may afford assistance when earth nuts have been employed to adulterate chocolate, the refractive index in the Amagat and Jean oleorefractometer being, for cocoa butter,  $-19^{\circ}$ , and for Arachis oil,  $+3^{\circ}$ , the presence of 5 per cent. of earth nuts altering the reading to  $-18^{\circ}$ , and 50 per cent. to  $-7^{\circ}$ . When earth-nut cake is used, this method is inapplicable.—C. S.

**Caffeine in Coffee and Tea, Estimation of.** A. Hilger and A. Juckenack. *Forsch. Ber. ü. Lebensm. u. ihre Bez. z. Hyg., &c.*, **4**, 49—50. *Chem. Centr.-Bl.* 1897, [1], 775.

20 grms. of finely ground coffee or powdered tea (raw coffee is dried as much as possible in the drying chamber before grinding) are soaked for some hours in 900 grms. of water at the ordinary temperature (3 hours for raw coffee and  $1\frac{1}{2}$  hours for roasted coffee and tea), and the mixture then raised to boiling, after adding water to compensate for evaporation. Cool to 60°—80° C., add 75 grms. of ammonium acetate liquor D. A. B., and whilst stirring, add 1.9 gm. of sodium bicarbonate; then boil for 5 minutes, and after cooling, bring the total weight up to 1,020 grms. with water. Filter, and evaporate on the water-bath, with stirring, 750 grms. of the perfectly clear filtrate (corresponding to 15 grms. of original substance) with 10 grms. of precipitated powdered aluminium hydrate, and some filter-paper shaken to a pulp with water; completely dry the residue, and exhaust for 8 hours with carbon tetrachloride in a Soxhlet's extractor. Distil off the carbon tetrachloride and dry and weigh the residue of perfectly white caffeine. The nitrogen in the crude caffeine can be estimated accurately by Kjeldahl's process and the amount of anhydrous caffeine thus calculated. The numbers obtained by titration are on the average 2 to 4 mgrms. less than the gravimetric results.

—A. S.

*Caffeine, Estimation of.* G. L. Spence. J. Amer. Chem. Soc. 1897, 19, 279—281.

THE author found in comparative experiments with a number of methods for the determination of caffeine in tea, the Gomberg method (this Journal, 1896, 384) gave the most satisfactory results, and admitted of a wider application than the gravimetric methods.—O. H.

*Caffeine in Tea, Estimation of.* C. C. Keller. Ber. Pharm. Ges. 1897, 7, 105; Chem. Zeit. Rep. 1897, 21, 102.

THE author recommends the following method:—6 grms. of dried tea leaves are added to 120 grms. of chloroform in a wide-necked separating funnel, and when the chloroform has come into thorough contact with the tea, 6 c.c. of 10 per cent. ammonia are added, the mixture being repeatedly and vigorously shaken for half an hour. The whole is then allowed to stand till the solution has become perfectly clear (in 3 to 6 hours) and the tea has completely absorbed the aqueous liquid. 100 grms. of the chloroform, corresponding to 5 grms. of tea, are now filtered through a small filter moistened with chloroform, into a small tared flask, and the chloroform distilled off on the water-bath. The residue is evaporated on the water-bath with 3 to 4 c.c. of absolute alcohol; the caffeine separates out in white crusts, whilst the chlorophyll deposits on the bottom. A mixture of 7 c.c. of water and 3 c.c. of alcohol is added, and the flask heated on the water-bath. The caffeine is thus dissolved, and the solution is filtered through a small filter moistened with water. The flask and filter are washed with 10 c.c. of water, the filtrate evaporated in a small, tared glass basin and the residue of pure caffeine weighed.—A. S.

*Butter Analysis, Methods of.* L. Drümel. Bull. Assoc. Belge des Chimistes, 10, [11], 411.

NATURAL butters, whether artificially coloured or not, are all decolorised by heat—boiling in a test tube for a few seconds—whereas the ordinary commercial margarines retain their colour under these conditions, and mixtures of the two exhibit partial decolorisation, the extent of which depends on the relative proportions of the constituents. The only exception observed by the author is in the case of margarines containing neutral lard, these behaving like natural butter; they are, however, rarely met with in commerce.—C. S.

*Filicic Acid, Various Methods of Determining, in Extract of Male Fern.* J. Pharm. Chim. 1897, 5, [6], 443.

KRAFT (Schweiz. Woch. für Chem. und Pharm. (35), 1896) recommends the following process:—5 grms. of the extract are agitated for 15 minutes with a solution of 2 grms. of potassium carbonate in 4 grms. of water and 60 grms. of 95 per cent. alcohol. 83 grms. of liquid are then filtered off into a separator, 9 grms. of 25 per cent. hydrochloric acid are added, followed by 50 grms. of ether and 35 grms. of water. The mixture is well agitated, the aqueous portion rejected, and the ethereal layer washed with another 35 grms. of water. The ether solution is then run into a tared flask, the solvent distilled off, and the residue evaporated to 2 grms. This is dissolved in 1.5 gm. of boiling amyl alcohol, 5 grms. of methyl alcohol are added, and then the filicic acid is precipitated by the further gradual addition of 25 grms. of methyl alcohol. The flask is then allowed to stand and well corked for 12 hours, when the precipitate is collected on a tared filter, washed with 10 c.c. of methyl alcohol, dried between 60 and 70° C. and weighed. The resulting weight of filicic acid represents the amount present in 4 grms. of original extract. The amount of filicic acid obtained from different specimens of commercial extract varies from between 0.4 and 10 per cent.

*Bouché's Method.*—This method (Boll. Chim. Farm. 1896, 149) is based on the fact that filicic acid of calcium is soluble in cold water, forming a solution from which it may be liberated by an acid. One or two grms. of the extract are dissolved in ether, and the solution washed with lime water until the latter is no longer coloured and gives no precipitation on acidulating a portion. The alkaline aqueous extracts are mixed and filtered into a separator and acidulated with acetic or hydrochloric acid; the filicic acid thus

liberated is washed out with carbon bisulphide, the solution filtered, evaporated to dryness on the water-bath, and weighed as filicic acid.

*Fromme's methods* (Pharm. Zeit. 1896, 41, 607, and *ibid.* 1897, 42, 44) closely resemble the preceding. From 1.5 to 2 grms. of the extract are weighed out into a small capsule, 2 grms. of ether added and then 3 grms. of magnesia are carefully triturated with the mass. When the ether has evaporated, water is gradually added to form a fluid paste. After standing for some time, the aqueous portion is thrown on a filter and the residue again treated with water and again filtered, the process being repeated until no precipitate is obtained on acidulating a portion with hydrochloric acid. The volume of the filtrate will then be from 200 to 250 c.c. This is acidulated with hydrochloric acid, and extracted in a separator with carbon bisulphide, in four successive washings. This extract is evaporated to dryness on the water-bath in a small tared flask. The dried residue is redissolved in 10 drops of amyl alcohol, and the filicic acid precipitated with methyl alcohol, and dried precisely as in Kraft's method. *Fromme's second method* consists of shaking together 5 grms. of extract, 30 grms. of ether, and 100 grms. of 2 per cent. barium hydrate solution. After agitation for five minutes, 86 grms. of the aqueous solution, equivalent to 4 grms. of extract, are run off; this weight is saturated with a slight excess of hydrochloric acid and extracted with four successive washings with ether. The ethereal extracts are evaporated to dryness in a tared flask, the residue redissolved in amyl alcohol, and precipitated with methyl alcohol, and finally weighed, as in Kraft's process, except that the drying is commenced at 40° C. The first step in the process should be rapidly conducted, or the barium hydrate will decompose a portion of the filicic acid.

—J. O. B.

*Thymol, Determination of, in Thyme Oil.* Kremers. Pharm. Rundschau. 1896, 221; Schimmel's Rep., April 1897, 41.

FIVE c.c. of the oil are weighed and introduced into a glass stoppered burette graduated in  $\frac{1}{10}$  c.c.; an equal volume of petroleum ether is then added, followed by a 5 per cent. solution of potassium hydrate; after well shaking together, the liquid is allowed to stand until separation is complete. The alkaline solution is then run off into a 100 c.c. flask, the residual oily liquid being again washed with alkali until no further decrease in the volume of the oil follows. The mixed washings are then made up to 100 or 200 c.c. with a 5 per cent. soda solution. To 10 c.c. of this solution in a graduated 500 c.c. flask  $\frac{1}{10}$  N. iodine solution in slight excess is added: it precipitates the thymol. This excess of the precipitant may be determined by the addition of a few drops of dilute HCl to a small portion of the liquid, if any thymol remains uncombined with the iodine, a turbidity results, whereas if iodine be in excess a clear brown solution is obtained. When this point is reached, the original liquid is rendered slightly acid with HCl and diluted to 500 c.c. From this 100 c.c. are filtered off, and the excess of iodine is determined by titration with  $\frac{1}{10}$  N. thiosulphate solution. The number of c.c. required, multiplied by 5 and deducted from the number of c.c. of iodine solution added, gives the number of c.c. of iodine solution used, each c.c. of which is equivalent to 0.003741 gm. of thymol.—J. O. B.

*Carvacrol, Determination of.* E. Kremers. Pharm. Rundschau. 1896, 221; Schimmel's Rep., April 1897, 41.

THE method of the determination of carvacrol is precisely similar to that given for thymol, with this slight modification—that after the iodine solution has been added, the mixture is vigorously shaken to cause the cohesion of the precipitate, and is then filtered. The filtrate is then acidulated with hydrochloric acid and the process continued precisely as described for thymol.—J. O. B.

*Sandalwood Oil, East Indian; Analytical Data of.* Schimmel's Rep., April 1897, 36.

A GENUINE sandalwood oil should have the following characters—specific gravity not below 0.975 at 15° C., optical rotation, 17°—19°. It should be soluble in 5 parts of 70 per cent. alcohol at 20° C., and should contain at least 90 per cent. of santalol. The latter constituent may

be determined as follows:—About 20 grms. of the oil are mixed with an equal volume of glacial acetic acid (or acetic anhydride, see Schimmel's Rep., Oct. 1895, 13), a little anhydrous sodium acetate is added and the whole gently boiled for an hour and a half. After cooling, the acetylated oil is washed, first with water, then with very dilute soda solution to remove free acid, and it is then dried by shaking with anhydrous sodium sulphate. From 2 to 5 grms. of this dry acetylated oil is weighed off and saponified by boiling with an excess of normal alcoholic potash solution under a reflux condenser. The amount of potash used up is then determined by titrating back with normal acid. The percentage of santalol may be found from the following formula—

$$P = \frac{a \times 22.2}{S - (a \times 0.042)}$$

where—

P = percentage of santalol.

a = the number of c.c. of potash used up.

S = quantity of acetylated oil weighed off.

—J. O. B.

**Acetone, Impt. of Squibbs' Volumetric Method for Estimating.** L. F. Kehler. J. Amer. Chem. Soc. 1897, 19, 316—320.

THE author has studied and worked with Squibbs' modification of Robineau and Rollin's method (this Journal, 1897, 168), and finding that a difficulty was experienced in obtaining pure acetone, and the drop final reaction being lengthy and tedious, has modified the method so that the use of pure acetone and the drop final reaction are dispensed with.

The solutions required are as follow:—

1. A 6 per cent. solution of hydrochloric acid.
2. A decinormal solution of sodium thiosulphate.
3. Alkaline potassium iodide solution prepared by dissolving 250 grms. of potassium iodide in water, made up to a litre; dissolving 257 grms. of sodium hydroxide (hy. alcohol) in water, likewise made up to a litre. After allowing the latter to stand, 800 c.c. of the clear solution are added to the litre of potassium iodide.

4. Sodium hypochlorite solution: 100 grms. of bleaching powder (35 per cent.) are mixed with 400 c.c. of water; to this is added a hot solution of 120 grms. of crystallised sodium carbonate in 400 c.c. of water. After cooling, the clear liquid is decanted, the remainder filtered, and the filtrate made up to a litre; to each litre is added 25 c.c. of sodium hydroxide solution (sp. gr. 1.29).

5. An aqueous acetone solution containing 1 or 2 per cent. of acetone.

6. Bicarbonated starch solution, prepared by treating 0.125 grms. of starch with 5 c.c. of cold water, then adding 20 c.c. of boiling water, boiling a few minutes, cooling, and adding 2 grms. of sodium bicarbonate.

To 20 c.c. of the potassium iodide solution are added 10 c.c. of the diluted aqueous acetone, an excess of the sodium hypochlorite solution is then run in from a burette and well shaken for a minute. The mixture is then acidified with the hydrochloric acid solution, and while agitated, an excess of sodium thiosulphate solution is added, the mixture being afterwards allowed to stand a few minutes. The starch indicator is then added and the excess of thiosulphate re-titrated. The relation of the sodium hypochlorite solution to the sodium thiosulphate being known, the percentage of acetone can be readily calculated.—O. H.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

**Chlorine Water, Preparation of.** G. Griggi. Bolletino Farmac. Chim. 1896, 680; Chem. Centr.-Bl. 1897, [1], 873.

PURE chlorine water may be obtained from lead dioxide (or red lead), oxalic acid, and calcium chloride, without use of apparatus, by the following formula—

—A. S.

**Strontium Chromate, Action of, on Mercuric Chloride.** G. Belugou. Bull. Soc. Chim. 1897, 17, 473—474.

ON digesting strontium chromate with a saturated solution of mercuric chloride on the water-bath, filtering, and cooling, fine orange crystals are deposited.

Analysis leads to the formula,  $2(3\text{HgCl}_2 \cdot \text{SrCrO}_4) \cdot \text{HCl}$ .

Basic mercuric chromate probably remains in the insoluble portion.—A. C. W.

**Strontium Chromate, Action of, on Mercuric Chloride.** H. Imbert and G. Belugou. Bull. Soc. Chim. 1897, 17, 471—473.

THE double salt,  $\text{SrCrO}_4 \cdot 2\text{HgCl}_2 \cdot \text{HCl}$ , is obtained by dissolving strontium chromate ( $\frac{1}{2}$  mol.) in concentrated hydrochloric acid, diluting and dissolving in the liquid mercuric chloride (1 mol.). After digesting on the water-bath and filtering, a salt of the above composition crystallises out in orange-red crystals. The compound is not decomposed by water, and recrystallises unchanged. In its solution ammonia produces a canary-yellow precipitate, which appears to be the body  $2(\text{HgCl}_2 \cdot \text{NH}_3) \cdot \text{HgCrO}_4$ .—A. C. W.

**Magnesium Methylate.** E. Szatvay. Ber. 30, [7], 806—809.

THE author had previously shown (Ber. 30, 305) that the chief product of the action of methyl alcohol on magnesium nitride was magnesium hydroxymethylate,  $\text{Mg}(\text{OH})(\text{OCH}_3)$ . Magnesium and methyl alcohol react together according to the equation—

If the reaction be carried out at a high temperature, magnesium methylate is left as a white powder readily decomposed by moisture.

At the summer temperature, methyl alcohol dissolves clean magnesium, converting it into a gelatinous precipitate; from a solution in the proper proportions, crystals, of the composition  $\text{Mg}(\text{OCH}_3)_2 \cdot 3\text{CH}_3\text{OH}$ , separate. This crystallised methylate is soluble in methyl and ethyl alcohols and in benzene, the amorphous compound is, however, almost insoluble; thus a solution of the crystalline compound on heating, deposits the amorphous substance.

The main reaction of bromine on the methylate takes place as follows:—

—A. C. W.

**Urea, Yield in the Transformation of Ammonium Carbonate into.** L. Bourgeois. Bull. Soc. Chim. 1897, 17, 474—477.

AMMONIUM sesquicarbonate was heated for six hours in a sealed tube at  $130^\circ$ . After cooling, the carbon dioxide was liberated, the tube again sealed, and heated once more for six hours. The whole process being several times repeated; finally on evaporating the contents to dryness on the water-bath, urea was left, mixed only with small quantities of its decomposition products (biuret, &c.). The yield varied from 3.2 to 9.52 per cent.; ammonium bicarbonate, treated in the same way gave 2.5 to 2.9 per cent., and ammonium carbonate 2.6 to 3.7 per cent.

In an experiment in a steel autoclave with the sesquicarbonate, 7.55 per cent. of urea was obtained; the autoclave was seriously attacked by the carbonic acid, a considerable quantity of ferrous carbonate being found in the liquid. In the absence of air, copper is unattacked under the same conditions.—A. C. W.

**Acetylene, Action upon Cupric Salts.** H. G. Söderbaum. Ber. 30, [7], 814—815.

ACETYLENE gives, in a cold ammoniacal solution of a cupric salt, a black precipitate, which, dried *in vacuo*, appears to have the formula  $12\text{C}_2\text{Cu} + \text{H}_2\text{O}$ . The precipitation takes place more slowly in a cold solution, but is quantitative. The composition of the acetylide is considerably influenced by the temperature of precipitation. With rapid heating the acetylide explodes at  $50^\circ\text{C}$ , but with a slow rise of temperature at  $70^\circ$ , or even  $80^\circ$  after long desiccation.

—A. C. W.

*Acetone, Condensation of [to Terpene-like Hydrocarbons], by boiling with Zinc Chloride.* P. N. Raikow. Ber. 30, 905—906.

Freshly distilled acetone when heated under a condenser with zinc chloride on a sand bath, becomes yellow and finally dark brown. After boiling for about 20 hours a mobile yellowish oil separates, which on adding more zinc chloride and continuing the boiling, becomes more and more viscid, darker, and begins to exhibit an olive-green fluorescence. For the purposes of the investigation an oil was taken resulting from boiling the mixture 30 hours. After separation from the lower layer, it was fractionated, a small portion passing over at 120°—150° C., the thermometer then rising continuously to 390° C. when the distillation was stopped. Two fractions boiling at 162° C. and at 252° C. were analysed and gave numbers which corresponded to terpenes rather than to mesitylene. A condensation of acetone with separation of water should only yield polymeric hydrocarbons of the general formula  $(C_5H_8)_n$ , whilst the formation of hydrocarbons of which the percentage numbers agree with those of the terpenes can only be explained on the assumption that a decomposition of the carbon chain in acetone, or in its condensation product, has taken place.—T. A. L.

*Arrow Poison from the Larva of a Beetle. (Diamphidia locusta.)* R. Boehm. Chem. Zeit. Rep. 1897, 79; Pharm. Centralh. 38, 277.

THE tribe of bushmen of that part of South Africa known as Kalahari use the juice of the leaf beetle *Diamphidia locusta* and its larva for poisoning their arrowheads. Lewin (Pharm. Centralh. 36, 599) found in its body besides inert fatty acids a toxalbumin which caused paralysis and finally, death.

To obtain a solution of the poison, Boehm recommends the maceration of the whole larva in distilled water for some hours, when they swell up, and the liquid, which now possesses poisonous properties, is light yellow in colour, and acid in reaction. This acidity is not removed by shaking out with ether. It gives the usual reactions for a toxalbumin, and can be precipitated from its aqueous solution with ammonium sulphate.—J. O. B.

*Diestase, Action of Light on, and its Biological Significance.* J. R. Green. Proc. Royal Soc. 1897, 61, 25.

See under XVII., page 549.

*International Congress on Technical Education.* Chem. and Druggist, June 19, 1897, 946.

THIS Congress was opened at the Society of Arts, Adelphi, on June 15th, the Duke of Devonshire presiding, after M. Léo Saignat, the retired president, formally gave up the office. The Duke of Devonshire explained that the meeting of the Congress in London was due to the Society of Arts and to the City companies, which had guaranteed the needful expenditure. He remarked on the beneficial effect of public conferences on educational questions, and thought the present time well chosen for an international congress on technical instruction, for in all countries there were signs of increasing interest in foreign methods of education. English education, he said, had been materially affected during the last 60 years by foreign influences. There was one point at least in which continental critics were now paying Great Britain the compliment of careful study and even of admiration. We had been recently working out an interesting and fruitful experiment in combining financial aid from the central exchequer with great liberty of action on the part of county and county borough councils. The policy of permitting local authorities to expend their share of the residue of the excise duties on technical education had probably done more than any previous act of the State to stimulate national interest in technical instruction. The local authorities, with few exceptions, had risen to their new duties with commendable alacrity and enterprise.

"The Teaching of Pure Chemistry and Applied Chemistry" was the first paper read, Prof. Otto N. Witt, of Berlin, being the author. In it he advocated a thorough grounding in pure chemistry as the best training for future

work, and deprecated specialism in the early part of the young chemist's career; that should come later. Prof. H. E. Armstrong read a paper on an allied subject, and Dr. J. H. Gladstone followed with one on teaching chemistry in continuation evening schools, stating that in Manchester there are arrangements for 12,451 pupils at evening schools, and for 6,619 in higher-grade day schools, science being provided for all, if they want it. At present 2,738 students are attending the practical chemistry laboratories. These papers opened the discussion on technical education, in the course of which Sir H. Roscoe stated that he recently visited some large colour works near Frankfurt, where 100 men were employed, including many highly trained scientific chemists who had devoted years to original research with a view to making new discoveries. One employé, who received 1,000*l.* a year, worked for several years without producing any results. But eventually he made a discovery which repaid the firm ten times over, and placed an entirely new branch of manufacture in their hands. That showed what could be done by the application of science.

An excellent paper on "The Teaching of Chemistry," by Prof. G. Lunge, was read by Sir H. Trueman Wood. Prof. Lunge held that, to raise English chemical industry to the foremost rank, it was necessary that the technical management of chemical factories should not be left in the hands of "rule-of-thumb" men, but should be entrusted to real chemists. These men should have a much fuller education than the majority of chemists seem to obtain in Great Britain at present. His views as to the kind of education necessary were the same as Prof. Witt's. He did not even think that, apart from isolated exceptions, high-class knowledge was much good to foremen, whose duty it was to carry out their instructions and to see that the men did their work as prescribed by the staff, but who were not to meddle with the chemical process itself. It seemed a great waste of time and means to give some superficial chemical teaching to tens of thousands of workmen on the remote chance that one of them might have some real benefit of it, while at the same time many hundreds of educated men were receiving a really efficient training in the same direction, many of whom could not find properly remunerated places owing to a great extent to the cheap labour of "bottle-washers."

On Wednesday, June 16th, the work was divided into two sections, one meeting in the Society of Arts' house and the other in the neighbouring premises of the London School of Economics. The proceedings in both sections consisted chiefly of papers and discussions by science teachers upon the methods of teaching and the people taught. Comparatively little was said about the teachers. Foreign delegates took part in the discussions, and some of the best papers were by them.

## New Books.

*ANALYSE DER FETTE UND WACHSARTEN.* VON DR. RUDOLF BENEDIKT. Dritte erweiterte Auflage, herausgegeben von FERDINAND ULZER (Vienna). Verlag von Julius Springer, Berlin. 1897. Price M. 12. H. Grevel and Co., 33, King Street, Covent Garden, London.

8vo volume, commencing with a frontispiece of Dr. Benedikt, and followed by a literary memoir, and a list of Benedikt's scientific contributions. After this follows Benedikt's preface to his second edition of this work, published in 1891. The present volume contains 654 pages of subject-matter, illustrated with 48 woodcuts, and followed by an alphabetical index.

The plan of the work is as follows:—I. Constituents of Fats and Waxes. A. Acids. B. Alcohols. II. Physical and Chemical Properties of the Fats and Waxes. III. Estimation of Non-fatty Constituents and Preparation of the Substance for Analysis. IV. Method of Determining the Physical Properties of the Fats. V. Elementary Analysis of Fats. VI. Qualitative Examination of a Fat of known Origin. VII. General Methods for Determining the Quantitative Composition of Fats and Fatty Mixtures. A. Quantitative Reactions. B. Quantitative Estimation of Single

Constituents of the Fats. VIII. Identification and Quantitative Determination of such Foreign Constituents as are either dissolved in the Fatty Substance or melted up with it. A. Estimation of the Unsaponified Matter present. B. Identification of Small Quantities of Fats in Mineral Oils. C. Investigation of the Unsaponifiable Constituents. D. Identification and Estimation of Pure Resin and Colophony in Fat. IX. Investigation of Materials and Products of the Fat Industry. A. Candles. B. Soaps. C. Turkey Red Oil. D. Lubricating Oils. E. Degras. F. Wool-dressing Oils ("Wollspickmittel"). G. Edible Fats. H. Oil Seeds and Oil Cakes. J. Glycerin. K. Acetin. L. ("Faktis") India-rubber Substitutes. M. Blown Oils. N. Investigation of Liquid Fats. A. Physical Methods. B. Different Solubility of Oils as a Means of Identification. C. Chemical Methods. XI. Investigation of Solid Fats and Waxes. XII. Description of the several Fats and Waxes. A. Liquid Fats. B. Solid Fats. XIII. Examples.

**JAHRESBERICHT ÜBER DIE LEISTUNGEN DER CHEMISCHEN TECHNOLOGIE, MIT BESONDERER BERÜCKSICHTIGUNG DER ELEKTROCHEMIE UND GEWERBESTATISTIK FÜR DAS JAHR 1896.** Von Dr. FERDINAND FISCHER. Mit 262 Abbildungen. Verlag von Otto Wigand, Leipzig, Germany. 1897. H. Grevel and Co., 33, King Street, Covent Garden, London. Price 2s.

In this annual report, the progress and position of chemical industry up to the end of the year 1896, are treated of. Trade statistics, with more special reference to the German Empire, are also given. The last Jahresbericht contained 1140 pages of subject-matter. The present one (1896) contains 1183. Alphabetical indexes covering 53 pages (names and subject-matter) are given. An index of German patents follows those of names and subject-matter.

The text is illustrated with 262 engravings referring to plant and apparatus. The following is a synopsis of the subjects treated of in the volume, the extent of each group and its treatment being indicated by the number of pages filled:—

Group I. Chemical Technology of Fuel (pages 5 to 102). II. Chemical Metallurgy (pages 103 to 252). III. Electrochemistry (pages 253 to 354). IV. Chemical Manufactures, Inorganic (pages 355 to 478). V. Chemical Manufactures, Organic (pages 479 to 686). VI. Glass, Pottery, Cements, Artificial Stone (pages 687 to 766). VII. Foodstuffs (pages 767 to 974). VIII. Chemical Technology of Fibres (pages 975 to 1039). IX. Other Industries connected with Organic Chemistry (pages 1040 to 1134). X. Apparatus (pages 1135 to 1177). It was remarked in the notice of the Jahresbericht for 1894 that the subject of Electrochemistry filled 85 pages; for 1895 it filled 106 pages; and in the present (1896) volume the text on this subject fills 103 pages.

**CHEMISCH - TECHNISCHES REPERTORIUM. UEBERSICHTLICHER BERICHT ÜBER DIE NEUESTEN ERFINDUNGEN, FORTSCHRITTE UND VERBESSERUNGEN AUF DEM GEBIETE DER TECHNISCHEN UND INDUSTRIELLEN CHEMIE, MIT HINWEIS AUF MASCHINEN, APPARATE UND LITERATUR.** Herausgegeben von Dr. EMIL JACOBSEN. 35. Jahrgang. 1896. Zweites Halbjahr. Zweite Hälfte. R. Gaertner's Verlagsbuchhandlung, Herman Heyfelder, Schönebergerstrasse 26, Berlin, S.W. 1897. H. Grevel and Co., 33, King Street, Covent Garden, London.

The second issue for the second half-year of 1896 of Jacobsen's Repertory of Chemical Technology, containing reports on the progress of the following branches of chemical industry:—

I. Foods. II. Paper. III. Photography. IV. By-products, Residues, Manures, Sanitation, Disinfectants, &c. V. Soaps. VI. Explosives, Matches, &c. VII. Preparation and Purification of Chemicals. VIII. Chemical Analysis. IX. Apparatus, Machinery, Electro-technology, Thermo-technology, Appendix, and New Books.

**HANDBUCH DER CHEMISCHEN TECHNOLOGIE** (Bolley's Technologie, 56. (Bd. I. 3, 3) Nachträge und Register). In Verbindung mit mehreren Gelehrten und Technikern bearbeitet, und herausgegeben von Dr. P. A. BOLLEY und Dr. K. BIRNBAUM. Fortgesetzt von Dr. C. ENGLER. Ersten Bandes dritte Gruppe.

**DIE CHEMISCHE TECHNOLOGIE DER BRENNSTOFFE.** Von Prof. Dr. FERDINAND FISCHER (Göttingen). Restlieferung zum dritten Heft, enthaltend Nachträge und Register. Friedrich Vieweg und Sohn, Braunschweig. 1897. H. Grevel and Co., 33, King Street, Covent Garden, London.

This forms the appendix and conclusion of the work of Fischer on the Chemical Technology of Fuel. The volume contains matter from pages 593 to 636 on the Measurements of Heat and Light, illustrated with numerous wood engravings. From pages 637 to 647 there follows the alphabetical index of the entire work.

**ANLEITUNG ZUR CHEMISCH-TECHNISCHEN ANALYSE FÜR DEN GEBRAUCH AN UNTERRICHTS-LABORATORIEN.** Bearbeitet von Prof. F. ULZER und Dr. A. FRAENKEL (Vienna). Verlag von Julius Springer, Berlin. 1897. Price M. 5. H. Grevel and Co., 33, King Street, Covent Garden, London.

This analytical work contains preface, table of contents, and subject-matter covering 188 pages, followed by an alphabetical index. The text is illustrated with 12 engravings of special excellence. The subjects of technical-analytical interest treated of, are as follows:—I. Alkali Manufacturing Industry, &c. II. Mortars, Cements, and Clays. III. Metallurgy (Iron, Zinc Blende, Zinc Dust, Ordinary and Refined Copper). IV. Alloys. V. Manures. VI. Sugar Industry. VII. Fermentation Industries. VIII. Fats, Waxes, and Mineral Oils. IX. Mordants and Tanning Matters. X. Textile Industry and Dyeing. XI. Coal-Tar Products.

**ANLEITUNG ZUR QUANTITATIVEN BESTIMMUNG DER ORGANISCHEN ATOMGRUPPEN.** Von Dr. HANS MEYER (Vienna). Verlag von Julius Springer, Berlin. 1897. Price M. 3. H. Grevel and Co., 33, King Street, Covent Garden, London.

Svo volume, containing preface, table of contents, index of abbreviations, introduction, and subject-matter filling 112 pages. An alphabetical index concludes the work. There are 12 illustrations.

The work is subdivided into the following sections:—I. Determination of the Hydroxyl Group. II. Of the Carboxyl Group. III. Of the Methoxyl Group. IV. Of the Ethoxyl Group. V. Of the Carbonyl Group. VI. Of the Methylimido Group. VII. Of the Ethylimido Group. VIII. Of the Nitrile Group. IX. Of the Amido Group. X. Of the Amine Group. XI. Of the Imido Group. XII. Of the Diazo Group. XIII. Of the Hydrazine Group. XIV. Of the Nitro Group. XV. Of the Iodo Group and the Iodoso Group. XVI. Of the Peroxide Group.

Appendix.—The iodine number, &c.

**ANLEITUNG ZU ANALYTISCH-CHEMISCHEN ÜBUNGSARBEITEN AUF PHARMACEUTISCH-UND TOXICOLOGISCHEN GEBIETE.** Zugleich als II. Auflage von Prof. Dr. A. MEYER'S "Handbueh der qualitativen Chemischen Analyse." Bearbeitet zum Gebrauche in Pharmaceutisch-chemischen Laboratorien von Dr. ED. SCHAEER und Dr. PAUL ZENETTI (Strassburg). Hermann Heyfelder, R. Gaertner's Verlagsbuchhandlung, Berlin, S.W. 1897. Price M. 5. H. Grevel and Co., 33, King Street, Covent Garden, London.

This little work contains preface, table of contents, and text covering 175 pages, followed by the alphabetical index. There are eight illustrative woodcuts. The work is subdivided as follows:—I. Chief Reactions of the more important Acids and Organic Preparations of Pharmaceutical Interest. II. Identification or Detection of Inorganic and Organic Poisons in Mixtures of Animal and Vegetable Substances. III. Volumetric Analysis of Preparations of Pharmaceutical Interest. IV. Some more important Exercises in Chemical Physiology. V. Quantitative Estimation of Alkaloids and other Active Principles in Pharmaceutical Drugs and Galenical Preparations. Processes of Separation. Appendix: Composition of Reagents. Atomic and Molecular Weights, &c.

## Prizes.

### PRIZES FOR TECHNICAL ESSAYS.

*Eng. and Mining J.*, May 22, 1897, 509.

The Industrial Society of Rouen, France, offers gold medals for a portable pyrometer indicating with accuracy temperatures above 300° C., for a new method of utilising the solid products of the distillation of petroleum, for the best lamp for burning acetylene, for the application of an industrial process for the extraction of sulphur from iron and copper pyrites, and for a rapid and accurate method of determining cobalt and nickel in the New Caledonia ores. The essays must be forwarded to the President of the Society before September 30. They must be written in French. The competition is open to members and non-members of the Society.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

#### NEW FRENCH SUGAR LAW.

*Bd. of Trade J.*, June, 1897, 663.

This is a translation of the text of the new French sugar law, which was published in the *Journal Officiel* of the 5th April last.

#### CUSTOMS DUTIES ON SUGAR IN FOREIGN COUNTRIES.

*Bd. of Trade J.*, June 1897, 679.

A statement showing the rates of Customs duties leviable on unrefined and refined sugar, and on molasses imported into the principal European countries and the United States, according to the latest information in the possession of the Board of Trade.

#### NEW CUSTOMS TARIFF OF CANADA.

*Bd. of Trade J.*, June 1897, 684.

The following are extracts from the resolutions proposed in the Committee of Ways and Means of the Canadian House of Commons relative to duties of Customs, excise, &c. in Canada, to take effect from the 23rd April last:—

*Resolved*,—That, unless the context otherwise requires,—

- (a.) The initials "n.e.s." represent and have the meaning of the words "not elsewhere specified";
- (b.) The initials "n.o.p." represent and have the meaning of the words "not otherwise provided for";
- (c.) The expression "gallon" means an imperial gallon;
- (d.) The expression "ton" means 2,000 pounds avoirdupois;
- (e.) The expression "proof" or "proof spirits," when applied to wines or spirits of any kind, means spirits of a strength equal to that of pure ethyl alcohol compounded with distilled water in such proportions that the resultant mixture shall, at a temperature of 60° F., have a specific gravity of 0.9198 as compared with that of distilled water at the same temperature.

The regulations respecting the manner in which molasses and syrups shall be sampled and tested for the purpose of determining the classes to which they belong with reference to the duty chargeable thereon, shall be made by the Controller of Customs; and the instruments and appliances necessary for such determination shall be designated by him and supplied to such officers as are by him charged with the duty of sampling and testing such molasses and syrups; and the decision of any officer (to whom is assigned the testing of such articles) as to the duties to which they are subject under the tariff shall be final and conclusive, unless, upon appeal to the Commissioner of Customs within 30 days from the rendering of such decision, such decision is, with the approval of the Controller, changed; and the decision of the Commissioner with such approval shall be final.

That, in the case of all wines, spirits, or alcoholic liquors subject to duty according to their relative strength of proof, such strength shall be ascertained either by means of Sykes'

hydrometer or of the specific gravity bottle, as the Controller of Customs directs; and in case such relative strength cannot be correctly ascertained by the direct use of the hydrometer or gravity bottle, it shall be ascertained by the distillation of a sample, and the subsequent test in like manner of the distillate.

That all medicinal or toilet preparations imported for completing the manufacture thereof or for the manufacture of any other article by the addition of any ingredient or ingredients, or by mixing such preparations, or by putting up or labelling the same, alone or with other articles or compounds, under any proprietary or trade name, shall be, irrespective of cost, valued for duty, and duty shall be paid thereon at the ordinary market value in the country whence imported of the completed preparation when put up and labelled under such proprietary or trade name, less the actual cost of labour and material used or expended in Canada in completing the manufacture thereof or putting up or labelling the same.

That all medicinal preparations, whether chemical or other, usually imported with the name of the manufacturer, shall have the true name of such manufacturer and the place where they are prepared permanently and legibly affixed to each parcel by stamp, label, or otherwise; and all medicinal preparations imported without such names so affixed shall be forfeited.

That packages, when imported, shall be subject to the payment of the following duties, viz:—

- (a.) All bottles, flasks, jars, demijohns, carboys, casks, hogsheads, pipes, barrels, and all other vessels or packages manufactured of tin, iron, lead, zinc, glass, or any other material capable of holding liquids, and all packages in which goods are commonly placed for home consumption, including cases, not otherwise provided for, in which bottled spirits, wines, or malt liquors, or other liquids are contained, and every package being the first receptacle or covering enclosing goods for purpose of sale, shall in all cases, not otherwise provided for, in which they contain goods subject to an *ad valorem* duty or a specific and *ad valorem* duty, be charged with the same rate of *ad valorem* duty as is to be levied and collected on the goods they contain, and the value of the packages may be included in the value of such goods.
  - (b.) Provided that all such packages as aforesaid containing goods subject to a specific duty only, and not otherwise provided for, shall be charged with a duty of 20 per cent. *ad valorem*.
  - (c.) That packages not herein-before specified, and not herein specially charged with or declared liable to duty, and being the usual and ordinary packages in which goods are packed for exportation according to the general usage and custom of trade, shall be free of duty.
  - (d.) Provided further, that all such special packages or coverings as are of use or apparently designed for use other than in the importation of the goods they contain, shall be subject to the same rate of duty as would thereon be levied if imported empty or separate from their contents.
- That when the Customs tariff of any country admits the products of Canada on terms which on the whole are as favourable to Canada as the terms of the reciprocal tariff herein referred to, are to the countries to which it may apply, articles which are the growth, produce, or manufacture of such country, when imported direct therefrom may then be imported direct into Canada, or taken out of warehouse for consumption therein at the reduced rates of duty provided in the reciprocal tariff set forth in Schedule D.
- (a.) That any question that may arise as to the countries entitled to the benefits of the reciprocal tariff, shall be decided by the Controller of Customs subject to the authority of the Governor in Council.
  - (b.) That the Controller of Customs may make such regulations as are necessary for carrying out the intention of the two preceding sections.

## Inland Revenue.

6. *Resolved*.—That it is expedient to amend section 130 of chapter 34 of the Act 49 Victoria (the Inland Revenue Act), as amended by section 1 of chapter 25 of the Act 58-59 Victoria, by repealing such section and substituting, in lieu thereof, as follows:—

There shall be imposed, levied, and collected on all spirits distilled the following duties of excise, which shall be paid to the collector of inland revenue as herein provided, that is to say:—

(a.) When the material used in the manufacture thereof consists of not less than 90 per cent., by weight, of raw or unmaltd grain, on every gallon of the strength of proof by Sykes' hydrometer, and so in proportion for any greater or less strength than the strength of proof, and for any less quantity than a gallon, 1 dol. 90 cts.

(b.) When manufactured exclusively from malted barley, taken to the distillery in bond, and on which no duty of Customs or excise has been paid, or when manufactured from raw or unmaltd grain, used in combinations, in such proportions as the Department of Inland Revenue prescribe, with malted barley, taken to the distillery in bond, and on which no duty of Customs or of excise has been paid, on every gallon of the strength of proof by Sykes' hydrometer, and so in proportion for any greater or less strength, and for any less quantity than a gallon, 1 dol. 92 cts.

(c.) When manufactured exclusively from molasses, syrup, sugar, or other saccharine matter, taken to the distillery in bond, and on which no duty of Customs has been paid, on every gallon of the strength of proof by Sykes' hydrometer, and so in proportion for any greater or less strength, and for any less quantity than a gallon, 1 dol. 93 cts.

Also to repeal so much of the Inland Revenue Act and amending Acts as determine the excise duty on vinegar, and to provide that the excise duties thereon and upon acetic acid shall be as follows:—

Vinegar manufactured in whole or in part from spirits in bond, 4 cents per proof gallon.

Acetic acid, produced by the destructive distillation of wood, 4 cents per proof gallon.

Provided, that the Governor-General in Council may establish regulations exempting acetic acid from excise duty in whole or in part, when used in the mechanical arts.

7. *Resolved*.—That it is expedient that a license fee of 50 dols. be collected in each fiscal year from every manufacturer of acetic acid.

9. *Resolved*.—The excise duties hereby fixed and determined shall come into force and effect on and after the 23rd day of April 1897.

[Following these resolutions are Schedules A., B., and C., which contain the duties leviable on all articles imported into Canada, a list of articles admitted free of duty, and of prohibited goods. These schedules it is proposed to publish in a future number of the *Board of Trade Journal*.]

Schedule D. reads as follows:—

"On all the products of countries entitled to the benefits of this reciprocal tariff, the duties mentioned in Schedule 'A' shall be reduced as follows:—

"On and after the 23rd day of April 1897 until the 30th day of June 1898 inclusive, the reduction shall in every case be one-eighth of the duty mentioned in Schedule 'A,' and the duty to be levied, collected, and paid shall be seven-eighths of the duty mentioned in Schedule 'A.'

"On and after the 1st day of July 1898, the reduction shall in every case be one-fourth of the duty mentioned in Schedule 'A,' and the duty to be levied, collected, and paid shall be three-fourths of the duty mentioned in Schedule 'A.'

"Provided, however, that these reductions shall not apply to any of the following articles, but such articles shall in all cases be subject to the duties mentioned in Schedule 'A,' viz.:—Ales, beers, wines, and liquors; sugars, molasses, and syrups of all kinds, the product of the sugar cane or beet-root; tobacco, cigars, and cigarettes."

## COAL IN THE PAS-DE-CALAIS.

*Bd. of Trade J., June 1897, 710.*

Her Majesty's Consul at Calais, in a report to the Foreign Office, states that in the department of the Pas-de-Calais the output was, in 1895, 11,110,470 tons, and 11,870,517 tons in 1896. In the Nord the output was, in 1895, 5,959,871 tons, and 5,226,754 tons in 1896. The increase, however, was not sufficient to compensate for the fall in prices from 10 fr. 79 c. to 10 fr. 38 c. per ton. The labour employed in the Pas-de-Calais district was 35,907 hands working in the pits, and 10,176 above ground.

For some years past several companies have been formed to search for coal in the neighbourhood of Calais, but with little or no success till quite recently, when one of these companies found a bed of coal near a small hamlet, called Estromannes, situated between Wissant and Blauc-Nez, some 12 kiloms. from Calais. The demand for further concessions continues to increase, and boring is actively carried on, and should the efforts be crowned with success, there is no doubt but that Calais would benefit considerably as a port of export.—(*Foreign Office Annual Series, No. 1899.*)

## A NEW SUGAR-CANE IN THE FRENCH WEST INDIES.

*Bd. of Trade J., June 1897, 711.*

In a report to the Foreign Office, Mr. Gustave Borde, Her Majesty's Acting Consul at Martinique, states that the disappointments that the planters were wont to experience in regard to the quantity of sugar-cane reaped, have greatly diminished since the introduction on the sugar plantations of a species of sugar-cane, known locally as the "Cristalline," which is to be met with in Saint Lucia as the "Caledonian Queen." It is generally believed that this new plant is a valuable acquisition, and will be most useful to agriculture. When young it grows very fast, being the reverse of the sugar-cane plants now under cultivation, the growth of which is slow. By its rapid growth the new plant covers ground quickly, and checks the development of the grass that would otherwise impede the spreading of its leaves. It resists more easily the irregularities of the seasons, and is able to sustain very long droughts. The "shot borer" seems to shun its company, or rather, if a few plants are attacked, their vegetation is not in any way impeded. Judging from the experiments tried during the past year particularly, this species of sugar-cane is as rich in saccharine matter as all the others that have been hitherto cultivated. Hence, wherever the ordinary plant dies out, the planters endeavour to introduce the "Cristalline," the good qualities of which were conspicuously manifested in many localities very seriously affected by the fungus or other cane disease. For many years chemists have been endeavouring to find out the cause of the disease, and have tried various methods of fighting it, but invariably failed.—(*Foreign Office Annual Series, No. 1897.*)

## REDUCTION OF ROYALTIES ON PHOSPHATES IN SOUTH CAROLINA.

*Bd. of Trade J., June 1897, 716.*

A report from H.M. Acting Consul at Charleston, states that, in accordance with a decision of the South Carolina State Phosphate Commission, the royalty on all phosphate rock mined in that State on and after April 1st, 1897, will be 25 cents currency, equal to about 1s. sterling per ton, instead of 50 cents per ton previously charged.

This reduction, however, under the final action of the Commission, just published, will not apply to rock on hand April 1st last, but previously mined, which will be required to pay the former royalty of 50 cents per ton. The reduction in the Carolina royalty has been brought about by the decline in prices and the keen competition in the business resulting from the growth of phosphate mining in Florida, Tennessee, and elsewhere during the past two or three years.

## THE MINING AND METALLURGICAL INDUSTRIES OF GERMANY.

*Bd. of Trade J., June 1897, 703.*

A despatch from the Commercial Attaché at Berlin, encloses memorandum, based on tables in the official

*Reichsanzeiger*, relating to the yield of mines and the products of metal works in the German empire.

The following table shows the quantity and value of the output of the various minerals in Germany and Luxemburg in the years 1895 and 1896:—

	Quantity.		Value.		Average Price per Ton.	
	1896.	1895.	1896.	1895.	1896.	1895.
	1,000 tons.	1,000 tons.	£ 1,000	£ 1,000	Marks.	Marks.
Coal .....	85,639	79,169	29,652	26,944	6'92	6'81
Lignite .....	26,767	24,788	3,046	2,900	2'27	2'34
Iron ores .....	14,162	12,349	2,569	2,053	3'64	3'33
Zinc ores .....	729	706	851	528	23'32	14'97
Lead ores .....	154	161	618	646	80'00	80'06
Copper ores .....	717	633	847	768	23'61	21'28
Silver and gold ores .....	18	10	119	85	129'09	157'51
Salt (rough) .....	541	522	731	712	26'88	27'28

The immense increase in coal, amounting to 6,470,000 tons, and valued at 2,708,000/., from 1895 to 1896 deserves great attention; and besides this there is for lignite an improvement of 1,979,000 tons, worth 146,000/. The increase

in iron ores is also large, being 1,813,000 tons, valued at 516,000/.

The following table shows the output of iron and other metal works:—

	Quantity.		Value.		Average Price per Ton.	
	1896.	1895.	1896.	1895.	1896.	1895.
	1,000 tons.	1,000 tons.	£ 1,000	£ 1,000	Marks.	Marks.
Raw iron .....	6,295	5,417	14,789	11,733	46'98	43'32
Zinc (block) .....	153	159	2,555	2,081	307'79	277'05
Lead .....	113	111	1,251	1,113	219'98	200'60
Copper .....	29	25	1,458	1,163	995'03	902'96

## ENGLISH CEMENT IN THE TRANSVAAL.

*Bd. of Trade J., June 1897, 718.*

H.M. Consul at Lorenzo Marques states that English cement, at one time a promising article of import to the Transvaal, has of late years, it is said, been almost entirely superseded at that port by German cement. This is partly attributed to the fact that the latter is packed in iron drums, which withstand the rough handling and exposure often injurious to the contents of the frailer barrels in which English cement continues to be exported.

Cement, however, is likely to form in the future an ever diminishing article of import into the Transvaal, since a factory, enjoying Government support and a protective tariff, has now been established in that country.

Portland cement might still recover the market were it not for this native product and the high charges levied in its interest by taxation, and an almost prohibitive railway charge.

## A NEW CRISIS IN GERMAN SUGAR PRODUCTION.

*U.S. Consular Reps. 53, [197], 167—170.*

According to the law passed by the German Parliament on 15th May 1896, the limit of production was raised from 1,400,000 tons, the amount stated in the original bill, to 1,700,000 tons per annum (raw sugar equivalent)—an amount that had been reached only once, and that in the campaign of 1894—95, which led to the crisis of the year following. Over-production—the principal danger to be feared, and, if possible, averted—was thus established by the new law as a permanent possibility. Furthermore, the contingent production authorised was to be double the increased home consumption, and this was distributed among the factories, not on the basis of their average annual production for five years previous, but on the basis of the highest figures reached during two of the three preceding years. As a result, this has stimulated the factories in 1896 to obtain the highest possible output, so as to entitle themselves to the largest share of the bounty. The effect of this has been to give important advantages to the large and wealthy factories over the smaller ones owned by the farmers and capitalists of small means. The new law has also fixed

the internal revenue tax on manufacture so low as to have but little value to the State, the revenue yielded being wholly out of proportion to the heavy export bounties to be paid, which have become, more than ever before, a burden to the treasury.

The effects of the new statute have now become apparent. The foreign sugar market responded to the increased export bounty by a proportionate decline in price, so that the German exporter now receives only the same price for his sugar as before, and of this price the German Government pays more and the foreign consumer less than hitherto, so that the net result has been, not to encourage the German sugar industry, but to supply Great Britain, the United States, and other importing countries, with cheaper sugar, and thus further demoralise and weaken the general market.

The outlook is so menacing that the Reichstag will be petitioned to make certain amendments in the existing statute, with the object of revising the method of "Contingentierung" (or additional quota distributed among the factories on the basis of the average annual production of each), so as to restrict instead of stimulating production, and to invite international negotiations for the gradual abolition of all export bounties, which have been proven to be simply a burden on the treasury which pays them for the benefit of non-producing foreign countries.

In conclusion, it is pointed out that if this attempt at revision fails, there will then remain, in the opinion of practical men, but one way out of the dilemma—the organisation of the whole German sugar-producing interest into a syndicate, an organisation which shall, by its own regulations, carefully restrain over-production and be content with what can be done to control prices of sugar by commercial action, and by regulating the supply in home and foreign markets.—J. L. B.

## GERMAN BEET-SUGAR RETURNS FOR 1895—1896.

*U.S. Consular Reps. 53, [197], 170—172.*

The following data are taken from the publications of the Imperial Statistical Bureau and Licht's reports:—

The campaign of 1895—96 proved more favourable than the preceding one. Although the area under cultivation

had been reduced and the yield per hectare diminished, the saccharine contents of the beet were higher, and the average price of raw sugar better than in 1894-95. The value of the total sugar production of 1,615,111 tons in 1895-96 was 363,400,000 marks, against 351,719,000 marks in 1894-95. The total area under cultivation being 376,669 hectares, each hectare yielded, therefore, a gross profit of 965.04 marks, as compared with 796.75 marks in 1894-95. After deducting the working expenses per hectare, the net profit comes out 237.04 marks, against 53.55 marks in 1894-95.

The area under cultivation was reduced from 411,441 hectares in 1894-95 to 376,669 hectares, or about 14½ per cent. The yield per hectare was 31 tons, against 32.9 tons in 1894-95; 42.94 per cent. were grown by the factories and 56.06 per cent. bought, as compared with 41.64 per cent. grown and 58.36 per cent. bought in 1894-95.

The number of factories in operation was reduced from 405 in 1894-95 to 397—three new factories having been established and 11 closed, nine permanently and two temporarily.

The beetroot crop was 11,672,816 tons, against 11,521,029 tons in 1894-95, or a decrease of 19.61 per cent.

The number of steam engines and horse-power used in the factories was 5,320 and 97,977 respectively, against 5,324 and 94,952 in 1894-95. The average time required to manufacture the beetroots into raw sugar was 75 days, as compared with 99 days in 1894-95. The saccharine contents were 13.19 per cent.; in 1894-95 they were 12.2 per cent. To manufacture 1 cwt. of raw sugar, 7.58 cwt. of beetroot were required, against 8.2 cwt. in 1894-95. The export decreased from 1,073,590 tons in 1894-95, to 964,963 tons. The home consumption increased from 623,874 tons in 1894-95 to 730,784 tons. This increase is only apparent, and was largely caused by the stipulations of the new sugar law (see preceding report), which increased the home-consumption tax from 18 to 20 marks per double cwt., and thereby caused an extensive withdrawal of sugar from the bonded stores prior to its going into effect.

The average consumption of sugar per head of population was 12.72 kilos., against 10.7 kilos. in 1894-95, which increase, however, for the reason just stated, should be considerably discounted.

The tax on sugar, less export bounties, yielded to the Government 103,701,000 marks, against 85,714,000 marks in 1894-95, which equals a tax of 1.97 marks per head of population, against 1.65 marks in 1894-95.

The total raw sugar production in Europe was as follows:—

Countries.	1895-96.	1894-95.
Germany .....	1,615,111	1,841,461
Austria-Hungary .....	791,405	1,055,821
France .....	667,853	792,511
Russia .....	783,189	615,958
Belgium .....	260,050	243,957
Holland .....	106,829	84,507
Denmark, Sweden, Italy, Roumania, Spain.	168,800	156,001
Total .....	4,893,537	4,789,405

—J. L. B.

## GENERAL TRADE NOTES.

### UNIFICATION OF THE METHODS OF TESTING.

A circular, signed by Professor Hermann Wedding, of the Berlin School of Mines, has been issued respecting the proposed establishment at Zürich of an International Society for the Unification of the Methods of Testing Materials of Construction. It is proposed to establish a central labora-

tory there, in charge of Herr von Juptner, and an appeal is made to the members of the Iron and Steel Institute to contribute towards the expenses of maintenance. Herr Krupp, Essen, has subscribed 50*l.* per annum, and the Austrian ironmasters have offered 350*l.* per annum. About 2,000*l.* a year will be needed. Subscriptions may be sent through Mr. Brough, Secretary of the Iron and Steel Institute.

### CHEMICAL IMPORTS INTO FRANCE.

*Chem. and Druggist*, May 29, 1897, 838.

According to the excellent little monthly circular published by the British Chamber of Commerce in Paris, the value of the imports of chemical products into France during the first quarter of 1897 showed an increase upon that of the first quarter of 1896, the figures being respectively 9,117,000 frs. and 8,778,000 frs. The circular in question will be found very useful by firms dealing with France. Specimen copies of it may be had upon application to the Secretary of the Chamber, 25, Bd. des Italiens, Paris.

### PHENACETINE IN U.S.A.

*Chem. and Druggist*, June 5, 1897, 871.

Judge Lacombe, of the United States Circuit Court, has decreed that Bayer's patents for the manufacture of sulphonal of October 30, 1888, and also for the manufacture of phenacetine of March 26, 1889, are good and valid, and has restrained a traveller named Henry Gill from infringing the patents by selling products which are not made by Bayer.

### DISINFECTANTS FOR RUSSIA.

*Chem. and Druggist*, May 29, 1897, 858.

The Imperial Russian *Official Gazette* contains a notification to the effect that all disinfectants purchased abroad by Russian imperial or civic authorities will be admitted into Russia free of Customs duty.

### THE INCREASING DEMAND FOR WOOD PULP.

*Scient. American*, 76, [23], 358.

In the year 1880, which marks the real beginning of the wood-pulp industry, there were, in the State of Maine, seven pulp mills, with capital invested of 440,000 *dols.*, an annual production of 300,000 *dols.*, and 12 paper mills, with a capital of 2,000,000 *dols.* and a production somewhat in excess of that sum. In 1890 there were 11 pulp mills, with capital invested of 2,695,611 *dols.*, and a production value of 1,518,611 *dols.* At the present time there are over 13,000,000 *dols.* invested in pulp and paper mills, giving employment, directly or indirectly, to over 5,000 men. New York state has a daily production of 1,800,000 *lb.* of wood pulp for books and newspapers; Wisconsin, a daily production of 670,000 *lb.*; Maine, 665,000 *lb.*; Massachusetts, 614,000 *lb.*; Pennsylvania, 403,000 *lb.*; and New Hampshire, Michigan, Ohio, and Vermont, a somewhat smaller amount. It is estimated that 1,000,000,000 feet of spruce logs are required to supply the mills with raw material. Spruce wood has invariably been employed for making the best white paper, though attempts have been made in Europe to utilise the pine for this purpose. Both the pine and the poplar are more easily worked into ground pulp than spruce, but the woods lack the strength needed for large newspaper sheets, and there is also a difficulty in disposing of the pitch and resin in pine. Hemlock is not suitable, as its fibre is more brashy and has less strength than spruce. The spruce trees are unfit for ordinary paper purposes until they have attained the age of 100 to 150 years.

With regard to the systematic culture and development of spruce trees, it is stated that the German pulp manufacturers, with an area smaller than that covered with spruce trees in New York state, have supplied all the raw material needed for their paper mills, and have annually exported over half a million dollars' worth. The forests are merely thinned out, the old trees being cut down as soon as they reach the proper age; and the results are so satisfactory that the supply of raw material is assured as long as the present system of forestry is continued.—A. S.

## BOARD OF TRADE RETURNS.

## SUMMARY OF IMPORTS.

Articles.	Month ending 31st May	
	1896.	1897.
	£	£
Metals.....	1,767,629	1,683,518
Chemicals and dyestuffs .....	461,252	481,832
Oils.....	581,125	574,728
Raw materials for non-textile industries.	3,183,085	4,143,172
Total value of all imports .....	33,349,988	36,336,348

## SUMMARY OF EXPORTS.

Articles.	Month ending 31st May	
	1896.	1897.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

- 12,133. E. Robinson. Cooling by evaporation. May 17.  
 12,224. D. N. Fleming. Improvements in appliances for storing and diffusing compositions for preventing internal crustation or corrosion of boilers and the like. May 18.  
 12,752. G. Watson. Improvements in furnaces for burning towns' and other refuse; applicable also to furnaces for general purposes. May 24.  
 12,768. E. Paul. Improvements in, and in apparatus for, the manufacture of salt from brine. May 24.  
 13,353. W. N. Twelvetyrees. Improvements in cleansing, drying, and disinfecting apparatus. May 31.  
 13,379. J. H. Rosenthal. Improved salinometer. May 31.  
 13,754. H. Tomkins. Improvements in means and appliances for charging open-hearth furnaces. June 4.  
 13,868. T. Melvin. Melvin's improved method of evaporating moisture. June 5.

13,908. C. E. Challis. Improved filters and attachments. June 5.

13,993. W. Schmidt. Improved construction of tubes for cooling and heating purposes; specially adapted for brewers, dyers, dairies, and other trade uses; also for condensing steam and vapours. June 8.

14,226. L. Lewis. An improved composition for preventing incrustation in steam boilers. Complete Specification. June 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

16,306. W. Oliphant. Apparatus for drying solid materials. June 16.

16,552. R. H. F. Finlay. Evaporating apparatus. June 9.

16,659. J. Foster. Apparatus for condensing steam vapour or gases, applicable also as a feed-water heater. June 9.

17,053. J. Foster. Evaporating apparatus. June 2.

17,105. F. D. Cummer. Separation and collection of solid matters held in suspension in aeriform fluids. June 9.

17,862. C. A. Kunzel, jun. Filters. June 16.

17,980. W. L. Wise.—From Solvay and Co. Decanting apparatus. June 16.

18,259. H. A. Jones. Deoxidising furnaces. June 9.

21,203. J. H. W. Ortmann and C. W. C. Herbst. New or improved apparatus for pasteurising liquids. June 9.

28,742. H. B. Wright. Mechanical water purifiers. June 9.

1897.

154. S. Shail. Muffle furnace. June 2.

7108. W. P. Thompson.—From A. Te-telin. Process and apparatus for spraying, distilling, evaporating, or concentrating liquids. June 2.

7534. H. A. Wheeler. A smokeless furnace. May 26.

8482. W. Tattersall. Heating or cooling apparatus. June 9.

9042. T. Fletcher and Fletcher, Russell, and Co., Ltd. Furnaces for use with light hydrocarbons as fuel. June 2.

9941. J. Klein. Apparatus for cooling, concentrating, evaporating, and graduating liquids. May 26.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

12,263. A. Preston. A new or improved apparatus for the manufacture of acetylene gas. May 18.

12,275. W. B. Hartridge. Improvements in the manufacture of artificial fuel blocks, and apparatus for that purpose. May 18.

12,422. A. Apps. Improvements in or relating to the storage of ozone. May 19.

12,440. E. Fessoirat. Improvements in the manufacture of incandescence bodies for illuminating purposes. May 19.

12,556. R. Quatanneus-Moens and E. Carreer-Dilger. A new or improved automatic apparatus for the production of acetylene gas. Complete Specification. May 20.

12,591. T. F. Ennis and F. S. Green. Improvements in the utilisation of the refuse obtained from gas works. May 21.

12,619. C. Jorisset and H. N. Ward. Improvements in and relating to apparatus for the generation and burning of acetylene gas. May 21.

12,660. V. von Pindter. Improvements in and connected with apparatus for consuming smoke. May 22.

12,930. Count A. J. De Montby. Improvements in the manufacture of artificial fuel. May 25.

13,081. F. Dresser. Improvements in apparatus for generating acetylene gas. May 27.

13,082. F. Dresser. Improvements in apparatus for generating acetylene gas. May 27.

13,103. F. H. Smith. Improvements in the manufacture of calcium carbide and the like, and in the method of using the same in lamps or generators. May 27.

13,191. F. G. Bartlett. Improvements relating to burners employed in incandescent gas-lighting. May 28.

13,496. F. A. Mitchell. Improvements in acetylene gas generators. Complete Specification. June 1.

13,667. D. Whalley, J. Hacking, and The Ideal Gas Co., Ltd. Improvements in acetylene gas plant. June 3.

13,671. E. H. Smith. An acetylene gas generator. June 3.

13,798. S. S. Bromhead.—From J. Peyré. Instruments in generators for acetylene gas. June 4.

13,899. R. Langhans. Improvements in the manufacture of incandescent media for lighting purposes. June 5.

13,905. E. Soxhlet, F. V. Bergh, A. Borremans, and V. Borremans. Improvements in the process of obtaining lighting, heating, and motive power, and in apparatus therefor. Filed June 5. Complete Specification. Date applied for Jan. 22, 1897, being date of application in Belgium.

14,015. F. Trendel. Improvements in apparatus for producing acetylene gas. June 8.

14,090. E. Jimeno. Improvements in apparatus for the production of acetylene. Complete Specification. June 9.

14,091. E. Jimeno. Improvements in or connected with gas holders for acetylene and other lighting gases. Complete Specification. June 9.

14,208. F. H. Haviland and W. H. Murch. Improvements in apparatus for automatically generating, storing, and supplying acetylene gas. June 11.

14,259. H. Kayser. Improvements in the manufacture of incandescent bodies for gas and other lighting. June 11.

14,260. O. R. Rangabe. Improvements in apparatus for generating acetylene gas. June 11.

14,264. F. de Bal. Improvements in incandescence hoods or mantles for illuminating purposes. June 11.

14,274. H. H. Leigh.—From F. Saldana. Improvements in apparatus for the production of acetylene gas. June 11.

14,275. H. H. Leigh.—From F. Saldana. Improvements in the construction of lamps for generating and burning acetylene gas. June 11.

14,313. G. W. Gaskill and R. F. Reeve. Improvements in apparatus for generating gas by the addition of a solid to a liquid. June 12.

14,339. C. Tellier. Improvements in tubes and other bodies for absorbing or radiating heat. June 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

9047. T. D. Farrall. Method of and apparatus for heating by electricity. June 9.

11,581. G. Moreau and A. Prillies. Gas lighting. May 26.

12,771. C. Whitfield. Process and apparatus for manufacturing producer and water-gas. June 9.

13,147. J. E. Atkinson and J. M. Labouchere. Automatic apparatus for the manufacture of acetylene gas. May 26.

15,064. G. E. Redfern.—From La Comp. Continentale d'Éclairage par le gaz acétylène et ses applications industrielles. Apparatus for the production of acetylene. June 16.

15,962. F. S. Thorn and C. Hoddle. Apparatus for generating, storing, and cooling acetylene gas. June 9.

16,692. W. L. Wise.—From E. Thomson. Manufacture of gas and apparatus therefor. June 9.

16,966. W. Nicholls. Manufacture of incandescence bodies for illuminating purposes. June 9.

16,984. H. Strache. Method or process of and apparatus for removing gaseous iron compounds from water-gas. June 16.

17,228. A. Verley. Apparatus for the production of ozone. June 9.

1897.

5236. C. B. v. Franco. Means for generating, holding, and burning acetylene gas. May 26.

5913. C. E. Alexandre. Apparatus for the manufacture of acetylene gas. May 26.

7921. J. B. de Lery. Burners for incandescence gas lighting. May 26.

7991. A. A. Stephenson. Composition and apparatus for enriching gas. June 2.

8552. H. Cousin. Apparatus for manufacturing acetylene. May 26.

10,186. D. C. Morency. Apparatus for generating acetylene gas. June 2.

10,199. W. P. Thompson.—From The Deutsche Acetylen Gas Gesellschaft mit beschränkter Haftung. Apparatus for developing acetylene gas. June 2.

10,249. W. P. Thompson.—From The Deutsche Acetylen Gas Gesellschaft mit beschränkter Haftung. Apparatus for the production and consumption of acetylene gas. June 16.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

##### APPLICATION.

10,665. W. Young and J. Fyfe. Improvements in and relating to retorts for the destructive distillation of shale. June 3.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

12,179. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of ethers of *m*-oxy-*p*-amidobenzoic acid. May 17.

12,180. H. Imray.—From The Chemical Works, Bindschedler. Process for obtaining new dyestuffs of the phthaleine series. Complete Specification. May 17.

12,181. H. Imray.—From The Basle Chemical Works, Bindschedler. Process for obtaining new dyestuffs of the phthaleine series. Complete Specification. May 17.

12,963. L. Lederer. A process for the production of indifferent (neutral) compounds of alkoxyated phenols. Complete Specification. May 26.

12,964. L. Lederer. Process for the extraction of the hydroxylated ethers of phenol from mixtures. Complete Specification. May 26.

13,104. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brüning. Process for the manufacture of brown to black dyestuffs. May 27.

13,216. J. Grossmann. A new or improved non-fermenting indigo vat to produce effects similar to wood and other fermentation vats. May 28.

13,420. C. D. Abel.—From The Aetien Gesellschaft für Anilin Fabrikation. Manufacture of a new red basic colouring matter. May 31.

13,709. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the production of aromatic aldehydes. June 3.

13,999. R. Holliday and Sons, Ltd., J. Turner, and H. Dean. Improvements in the manufacture of naphthylamine derivatives and colouring matters therefrom. June 8.

14,043. J. E. Bedford and C. S. Bedford. Improvements in the treatment of logwood colouring matter. June 9.

14,132. H. R. Vidal. Improvements in the manufacture of colouring matters. June 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,955. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new products and colouring matters from aromatic nitro derivatives. May 26.

16,449. R. Vidal. Colouring matters. June 9.

16,582. T. R. Shillito.—From J. R. Geigy and Co. Production of azo colours. June 16.

17,064. I. Levinstein and Levinstein, Ltd. Production or manufacture of new colouring matters. June 9.

17,065. I. Levinstein and Levinstein, Ltd. Manufacture or production of new colouring matters. June 16.

17,207. O. Imray.—From G. H. Weiss. Manufacture of amino-oxy-carbonic acid and azo dyestuffs therefrom fixed on chrome mordants. June 2.

17,226. E. H. Temple. Improved ink. June 2.

17,590. S. Pitt.—From L. Cassella and Co. Manufacture of primary disazo dyestuffs. June 16.

17,591. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Production of dyestuffs on fibre. June 16.

18,720. T. R. Shillito.—From J. R. Geigy and Co. Production of red colouring matters. June 16.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS.

12,541. C. L. Bachelier. Improvements in the treatment of textile plants to remove the fibre therefrom. Complete Specification. May 20.

13,256. I. Johnstone and D. Scott. Improvements in or relating to treating, preparing, or applying cellulose for dressing or finishing textile fabric, or for other purposes. May 28.

13,274. E. Neuweiler. Improvements in the manufacture of yarns. May 28.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

13,273. A. S. Oetzmann and S. J. Narracott. Manufacture of inlaid fabrics for covering floors and other surfaces, and apparatus therefor. June 16.

13,815. W. Warburton. Extracting vegetable fibres. June 2.

19,351. J. McCreath. Wool drying. June 9.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

##### APPLICATIONS.

12,940. J. V. Johnson.—From The Badische Anilin and Soda Fabrik. Improvements in dyeing vegetable fibre with indigo. May 25.

13,088. H. Zublin and A. Zuigg. An improvement or improvements in white and colour discharge on envelope printing of dyed para-nitraniline red and related substances. Complete Specification. May 27.

13,138. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. An improved process for producing fast shades on cotton. May 27.

13,475. J. Grossmann. A new or improved method of producing indigo resist and similar styles. June 1.

13,591. J. Holden and S. Woods. Improvements in or relating to the manufacture of embossed or raised paper for covering walls, and for other purposes. June 2.

13,916. B. Willcox.—From S. Wallach and Co. and C. Scheen. Improvements in fixing insoluble colouring matters on fibres or fabrics. June 5.

14,319. V. Floquet and L. Bonnet. Improvements in bleaching and disinfecting fibrous materials, and apparatus for that purpose. June 12.

#### VII.—ACIDS, ALKALIS, AND SALTS.

##### APPLICATIONS.

12,266. The Compagnie Generale L'Alumine Soc. Anonyme. A new process of manufacture of double chloride of aluminium and soda. Complete Specification. Filed May 18. Date applied for Nov. 19, 1896, being date of application in Belgium.

12,274. S. Rosenblum, S. Rideal, and The Commercial Ozone Syndicate, Ltd. Improvements in the manufacture of hydrogen peroxide and in apparatus therefor. May 18.

12,387. A. J. Bambridge and G. Weddell. Improvements in the manufacture of bicarbonate of ammonia; also other compounds of carbon dioxide and ammonia and bicarbonate of soda. May 19.

12,534. A. R. Davis. Improvements in the manufacture of sodium chlorate. May 20.

12,768. E. Paul. Improvements in and in apparatus for the manufacture of salt from brine. May 24.

12,817. F. Blum. Process for the production of divisional products of halogen-albumen by means of alkalis. May 21.

12,952. E. G. Scott. Improvements in the manufacture of acetic acid. May 25.

12,982. W. Mills. Improvements in manufacturing the silico fluoride of ammonium. May 27.

13,280. H. Imray.—From L. Buchner. Process for producing alkali phosphates. May 28.

13,519. W. Feld. Process and apparatus for obtaining barium oxide and barium hydroxide from barium carbonate. June 1.

13,550. A. Royers. Process for the extraction of chlorine from halogen salts in solution in water, and the transformation of the light or heavy corresponding metal either into oxidised salts or oxidised salts of chlorine, and for the production with alkaline sulphates of the corresponding hydroxide salts. June 1.

13,551. W. Majert. A new process for the production of ammonium bichromate. Complete Specification. June 1.

13,825. H. Steinem and K. S. Murray. Improvements in and apparatus for the manufacture or production of carbonic acid gas. June 4.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,255. L. M. Bullier. Manufacture of carbides of the earth metals and alkali-earth metals. May 26.

1897.

2308. G. F. Zacher. Process for producing oxalic acid. June 9.

7192. A. Schmidt. Process and apparatus for the production of the acetates of lead, copper, and the like. June 9.

10,501. A. Feldmann. A process for removing carbonic acid and hydrogen sulphide from ammoniacal liquor. June 9.

#### VIII.—GLASS, POTTERY, AND ENAMELS.

##### APPLICATION.

12,759. W. Wachter. Method of transferring meta-chromo types upon ceramic objects before glazing the latter. May 24.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,901. K. W. R. Goerisch. Manufacture of sulphate glass. June 16.

14,953. H. Propfe. Manufacture and production of water-glass with valuable by-products of the said manufacture. May 26.

1897.

6184. E. Walsh, jun. Plate-glass annealing kilns. June 2.

10,430. H. de Wit. Manufacture of enamelled ceramics with a slaggy biscuit covered over with coloured enamel. June 16.

11,735. G. Tasche and F. Sporer. Glass cooling or annealing ovens. June 16.

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

##### APPLICATIONS.

13,026. W. Chrometzka. Improvements in fireproof ceilings. Complete Specification. May 27.

13,821. G. F. Lebioda. Improvements in apparatus for drying and hardening wood. Complete Specification. Filed June 4. Date applied for Nov. 14, 1896, being date of application in France.

14,068. J. A. Fisher. Improved fireproof ceilings and partitions. Complete Specification. June 9.

14,295. A. Patrick. Improvements in the manufacture of Portland or similar cement. June 12.

14,299. A. D. Elhers. Process of treating blast-furnace slag for use in cement, mortar, or the like. June 12. Date applied for Nov. 25, 1896, being date of application in United States.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

15,316. S. P. Davies.—From G. Frederick. Composition for use in streets, roads, pavements, and the like, and on the surfaces of wood and metal. June 2.

1897.

9315. C. Richardson. Asphaltic pavements and the like. June 2.

#### X.—METALLURGY, MINING, Etc.

##### APPLICATIONS.

12,325. J. C. Bull. Improvements in alloys. May 18.

12,442. C. D. Jenkins. Improvements in the production of aluminium and in apparatus therefor. May 20.

12,691. G. Weil, E. Quintaine, and C. Lepseh. Nickeling, silvering, gilding, &c. of aluminium. May 22.

12,796. F. W. Dupré. Improvements in or relating to the extraction of gold and silver from ores. May 24.

12,832. J. Golding. Improvements in furnaces specially applicable for the manufacture of lead. May 24.

13,302. C. P. Shrewsbury and H. R. Gregory. Improvements in means or apparatus for extracting gold and other metals from solutions containing such metals. May 29.

13,308. J. Parry and G. H. Llewellyn. Improvements in the manufacture of steel. May 29.

13,672. W. E. Harris. Method of treating and annealing sheet metal. Complete Specification. June 3.

13,739. J. P. van der Ploeg. Improvements in or relating to the treatment of antimonial and arsenical ores. June 4.

14,007. B. K. Jamison. Improvements in apparatus employed in the face-hardening of armour-plates or other articles of steel, or of steel alloyed with other metals. June 8.

14,325. C. C. E. Bohne. Improvements in the treatment of slag resulting from the smelting of tin ore. June 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

6654. A. Karyscheff and S. Demmenie. A new pyrochemical process and apparatus for the direct production of iron and other metals from their ores. June 2.

11,245. Davies Bros. and Co., Ltd., E. A. Davies, and S. T. Thomas. Preparing metal sheets for purpose of galvanising them or otherwise coating them with metal or metallic alloy. May 26.

11,839. A. S. R. Robinson. Method and machinery or apparatus for extracting gold from crushed ore or material containing it. June 2.

12,056. M. L. Ross.—From E. Oberle. Manufacture of refractory metallic threads. June 9.

12,396. E. A. G. Street. Fusing chromium and similar metals, and manufacture of alloys of such metals. May 26.

12,467. E. A. G. Street. Manufacture of alloys. May 26.

13,169. B. Mohr. Treatment of sulphide ores for the separation of zinc from the lead and other metals. June 16.

15,041. L. Doig.—From The Russel and Erwin Manufacturing Co. Annealing metals. May 26.

15,699. G. Ducean. New metallic alloy. May 26.

15,749. O. Murray.—From E. F. Turner. Improved regenerative process for the treatment of sulphide ores. June 16.

16,312. A. M. Clark.—From E. A. Ashcroft. Treatment of solutions of ores containing zinc, for the recovery of zinc as oxide. June 2.

16,685. C. Vautin. Production of metals and alloys. June 16.

17,493. C. W. H. Gopner and H. L. Diehl. Recovery of gold and silver from their solutions. June 16.

1897.

6151. F. A. Gooch. Processes for reducing aluminium. June 9.

11,602. E. F. von der Linde. Treatment of tin oxide in the form of powder, sludge, or paste, for the smelting thereof. June 16.

#### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

##### APPLICATIONS.

12,544. H. P. M. Brunel. Improvements in the process and apparatus for the electrolysis of alkaline solutions and the like. May 20.

12,549. W. Majert. Improvements in plates for accumulators. Complete Specification. May 20.

12,665. H. Tee. The combined generation and application of electricity supply and the manufacture of salt. May 22.

12,675. R. Krayn and C. Koenig. Improvements in galvanic batteries. Complete Specification. May 22.

12,827. V. Jeanty. Improvements in electric primary and secondary batteries. Filed May 24. Date applied for Nov. 19, 1896, being date of application in France.

13,100. C. N. Gauzentés. Improvements in or connected with primary or galvanic electric batteries. May 27.

13,363. H. Nehmer and F. Nehmer. Improvements in apparatus for distributing gas, liquids, solids, or particles of solids by electricity. May 31.

13,689. E. A. Jahncke. Improvements in or relating to electric batteries. June 3.

13,735. W. Rowbotham. Improvements in primary batteries. June 3.

13,992. W. Mather. Improvements in anodes for electrolytic cells. June 8.

14,022. R. Memmo. New electric furnace for the manufacture of carbide of calcium, with continuous operation, and with water covering for the gas. June 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

11,133. G. Bell and G. W. Bell. Apparatus for electrolytic decomposition of liquids. May 26.

13,646. W. H. Smith and W. Willis. Electric accumulators or storage batteries and manufacture of plates or electrodes therefor. June 9.

14,393. P. Jensen.—From H. C. F. Stormer. Anodes for electrolytic purposes. June 9.

16,270. M. O. A. Garreau. Secondary electric batteries. May 26.

16,516. J. Vaughan-Sherrin and H. H. Sherrin. Accumulator batteries. June 2.

17,161. S. Hammacher. The manufacture of an improved active material for the plates or electrodes of electric accumulators. June 9.

17,879. V. M. Coroely and L. C. H. Dantel. Electric batteries. June 16.

1897.

9563. H. T. Cheswright. Plates for secondary batteries or accumulators. May 26.

9913. E. Marekwald. A manufacture of electrodes for electric accumulators. May 26.

9914. E. Marekwald. A manufacture of electrodes for electric accumulator plates. May 26.

10,254. W. A. Boese. Process for the manufacture of accumulator plates. June 2.

**XII.—FATS, OILS, AND SOAP.****APPLICATIONS.**

- 12,456. R. T. Cardell. Improvements in soaps and all toilet preparations. May 20.  
 13,807. I. Kohn and M. Kohn. Improvements in or relating to transparent soap blocks or tablets containing inscriptions. Complete Specification. June 1.  
 14,238. J. Davidson and C. G. Hepburn. Improvements in apparatus for refining fats and oils. Complete Specification. June 11.  
 14,241. L. Grote. Bleaching soap. June 11.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

- 16,129. C. H. Simpson and F. H. T. Allan. Process for the purification of spent lyes. June 2.  
 24,090. T. H. Bateman. New or improved liquid soap. June 9.

1897.

9311. F. Rapp-Rosenthal. Process for the production of oil from peat. June 9.  
 10,526. J. R. Whiting and W. A. Laurence. Process and apparatus for deodorising oil. June 2.

**XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.****APPLICATIONS.**

- 13,829. H. C. P. Graves. A new or improved compound for use as a substitute for india-rubber, leather, or other substances, or for any other purposes to which it may be applicable. May 24.  
 13,534. E. P. von Wilmowsky. Improvements in purifying gutta-percha and similar matters or gums. Complete Specification. Filed June 1. Date applied for Nov. 4, 1896, being date of application in United States.  
 14,105. F. Boyling, C. L. Garland, and A. Ogden. An improved enamel paint and method of applying the same. Complete Specification. June 9.  
 14,262. H. E. Serullas. An improved process for obtaining gutta-percha. June 11.  
 14,272. P. H. Hansen and J. K. Westergaard. Improvements in the manufacture of casein compounds for electric insulating and other purposes. Complete Specification. June 11.

**COMPLETE SPECIFICATION ACCEPTED.**

1896.

- 17,031. A. M. Clark.—From W. Hampe and C. Schnabel. Manufacture of zinc pigments. June.

**XIV.—TANNING, LEATHER, GLUE, AND SIZE.****APPLICATIONS.**

- 12,326. S. Herzberg. A new or improved vegetable glue and a process for manufacturing the same. Complete Specification. May 18.  
 12,449. P. G. Sanford. Improvements in the treatment of blood and other albuminous matter, both animal and vegetable, for use in manufactures and the arts. Complete Specification. May 20.  
 12,450. P. G. Sanford. Improvements in the treatment of tanning liquids for clarifying, bleaching, or decolorising them. May 20.  
 12,712. H. Bremer. An improved process for the solution of organic albuminous substances and for the production of soluble preparations of albumen. May 22.  
 13,310. J. B. Scammell. Improvements in artificial leather compounds. May 29.  
 13,459. A. Hollings and J. Young. Improvements in apparatus for tanning or treating hides or skins and leather. June 1.  
 13,778. W. Sagar, sen., A. P. Sagar, and W. Sagar, jun. Improvements in the method of and apparatus for removing grease or fatty matter from sheep skins and other leather and the like. Complete Specification. June 4.

13,997. W. Turner. Improvements in means or apparatus for working or treating skins, hides, or leather. June 8.

14,052. J. E. Chevallot. The manufacture of new iron compounds and their application to the preparation of leather. Filed June 8. Date applied for Dec. 8, 1896, being date of application in France.

14,076. C. J. Dunn. Improvements in or relating to the tanning of leather. June 9.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

13,096. T. H. Cobley. Treatment of waste substance for the production of leather board and material suitable for being pressed into form for decorative and other purposes, or for use in substitution for leather floorcloth and the like. June 16.

1897.

11,111. E. O. Daniel. Preparation for and tanning of hides and skins. June 9.

**XV.—AGRICULTURE AND MANURES, Etc.****APPLICATION.**

13,811. I. Kovacs. An improved process for making a consistent friable artificial manure. Complete Specification. June 4.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

16,861. R. Tuggener. Apparatus for turning fecal matter into manure and for disinfecting water-closets. May 26.

1897.

9704. C. H. Thompson. Manufacture of improved fertilised and fertilising materials. June 2.

**XVI.—SUGARS, STARCHES, GUMS, Etc.****APPLICATIONS.**

- 13,357. W. Powell. Improvements in or connected with the manufacture of sugar. May 31.  
 13,358. W. Powell. Improvements in or connected with the manufacture of sugar. May 31.  
 13,962. M. von Schmidt. A process to dissolve gum which is otherwise indissoluble. June 8.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

16,009. W. Field. Extracting sugar from molasses by means of barium hydroxy-sulphide, and recovering the same from the resulting by-products. June 16.

16,111. W. Feld. Extracting sugar from molasses by means of barium hydroxy-sulphide, and recovering the latter. June 9.

17,536. E. J. Mills. Formation and preparation of soluble colloids of the gelatine class. June 9.

1897.

9108. A. J. Boulton.—From C. M. Higgins. Adhesive compounds. May 26.

**XVII.—BREWING, WINES, SPIRITS, Etc.****APPLICATIONS.**

- 12,958. H. Krausz and L. Vass. Process for utilising the waste of hops and malt of breweries. Complete Specification. May 25.  
 13,312. P. F. Van der Gucht and A. Kreps. New or improved malting apparatus. May 29.  
 13,435. A. J. Boulton.—From G. R. Besser. Improvements in apparatus for treating or maturing fluids containing alcohol. May 31.  
 13,722. J. Goodfellow. Manufacture of nutritious products from yeast. June 3.  
 14,106. N. Bendixen. Improvements in propagating apparatus for developing pure culture of yeast and bacteria. Complete Specification. June 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,671. J. Dunn. Treating barley for alimentary purposes, including brewing and distilling. June 2.

1897.

5582. L. Prochazka and E. Frischauer. Process and apparatus for mashing and brewing. May 26.

10,180. M. van Look. Process for the preparation of mead. June 2.

## XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.

## APPLICATIONS.

*A.—Foods.*

12,731. R. G. Nash. Improvements in the aeration and preservation of milk, and apparatus therefor. May 22.

13,141. H. Higgins. Improvements in or relating to the treatment of separated milk for alimentary purposes. May 27.

13,142. H. Higgins. Improvements in or relating to the treatment of separated milk for alimentary purposes. May 27.

13,143. H. Higgins. Improvements in or relating to the treatment of separated milk for alimentary purposes. May 27.

13,985. E. B. Watson. Improvements in enriching vegetable and other foods. June 8.

*B.—Sanitation.*

12,984. F. P. Candy. Improvements in the connection with the purification of sewage and polluted water. May 27.

13,400. W. D. Scott-Monerieff. Improvements in or relating to the purification of sewage, and apparatus therefor. May 31.

13,429. H. Melphail. Improvements in the purification of liquids. May 31.

11,058. W. J. Lomax and T. Aspinall. Improvements in or relating to the treatment and purification of sewage and other polluted waters and liquids. June 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Foods.*

1896.

11,637. A. J. Vause. An improved process for preserving milk and certain other classes of fresh foods by sterilisation. May 26.

17,720. H. M. Amos. Fruit evaporators. June 16.

1897.

6065. H. Humbert. Process for drying substances. June 2.

*B.—Sanitation.*

1896.

15,456. E. Sergeant. Combined apparatus for burning refuse and disinfecting. May 26.

## XIX.—PAPER, PASTEBOARD, ETC.

## APPLICATION.

12,208. W. A. Hall. Improvements in the manufacture or treatment of paper. May 17.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

12,399. S. Smithson. Improvements in or relating to machinery or apparatus for treating myrobolams for obtaining extracts therefrom. Complete Specification. May 19.

13,055. W. Simpson. New or improved method of preparing fruit or other essences and extracts in tablet form. May 27.

13,214. J. B. Cohen. Improvements in the method of preparing aldehydes and ketones from alcohols. May 28.

13,917. B. Willcox.—From C. Goldschmidt. The manufacture or production of new pharmaceutical products. June 5.

13,993. H. Imray.—From F. Hoffmann, La Roche, and Co. Manufacture of bisnuthoxyiodide pyrogallate. June 8.

14,305. M. Otto. Improvements in apparatus for extracting the essential matters contained in aromatic plants, and analogous purposes. June 12.

14,328. J. E. T. Woods. Further improvements in the manufacture of substitutes for camphor, called camphorete, and products made therefrom. Complete Specification. June 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,928. H. Imray.—From Harmann and Reimer. Process for the manufacture of vanilline from iso-eugenol and eugenol. June 2.

17,177. J. J. A. Trillat. Production of vapours of formic aldehyde and apparatus therefor. June 16.

## XXI.—PHOTOGRAPHY.

## APPLICATIONS.

12,922. T. C. Porter. A new or improved sensitive plate or film, and a method of producing, developing, fixing, and toning the same. May 25.

## XXII.—EXPLOSIVES, MATCHES, ETC.

## APPLICATIONS.

12,701. F. Render. Improvements in explosive cartridges. May 22.

13,064. S. Rolfe. Improved method of detonating explosive compounds. May 27.

13,552. W. Majert. A new explosive compound. Complete Specification. June 1.

13,611. G. de Wolf. An improved method of manufacturing gunpowder. June 2.

13,624. F. Render. Improvements in apparatus for the manufacture of cartridges of explosive substances for blasting and similar purposes. June 2.

13,724. E. A. G. Street. Improvements in or relating to the manufacture of explosives and explosive substances. June 3.

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dowar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Dr. Edward Schunck, F.R.S.	1896—1897.

## COUNCIL FOR YEAR ENDING JULY, 1898.

President: Prof. F. Clowes, D.Sc.

### Vice-Presidents:

David Howard.	Dr. W. Jay Schieffelin.
Prof. A. K. Huntington.	Dr. Edward Schunck, F.R.S.
Ivan Levinstein.	G. N. Stoker.
Boverton Redwood.	Dr. T. E. Thorpe, F.R.S.
Sir H. E. Roscoe, F.R.S.	Wm. Thorp, B.Sc.
A. Gordon Salamon.	Thomas Tyrer.

### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
R. Le Nere Foster.	J. S. McArthur.
Sir David Gamble, Bart., C.B.	B. E. R. Newlands.
Oscar Guttman.	John Pattinson.
Douglas Herman.	Sir Robert Pullar.
Prof. J. J. Hummel.	Walter F. Reid.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

### General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

A. H. Allen.	C. Clarke Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	J. Lewkowitzsch, Ph.D.
H. Brunner.	A. R. Ling.
A. C. Claudet.	Stevenson Macadam, Ph.D.
E. Rider Cook.	Ludwig Mond, F.R.S.
Chas. Dreyfus.	B. E. R. Newlands.
Sir John Evans, K.C.B., F.R.S.	John Pattinson.
G. G. Henderson, D.Sc.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	H. R. Procter.
D. B. Hewitt, M.D.	Boverton Redwood.
David Howard.	Walter F. Reid.
Prof. J. J. Hummel.	John Spiller.
Prof. A. K. Huntington.	William Thorp.
F. Hurter, Ph.D.	Thomas Tyrer.

## NOTICES.

The Society's Office will be closed from August 30th to September 14th next, and the General Secretary will feel obliged if members who have changes of address to communicate will send them in before that date.

### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, part of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List	Each copy 10s.
To Subscribers .....	12s. 6d.
To others.....	15s.

## JUBILEE HONOUR LIST.

Her Majesty has been pleased to confer the honour of knighthood on George J. Smith, Esq., of Tuckingmill, Cornwall.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

## LIST OF MEMBERS ELECTED 14th JULY 1897.

Ablett, A. W., Rand Central Ore Reduction Co., Box 1891, Johannesburg, S.A.R., Cyanide Works Manager.  
Ackermann, Eugene, 132, Alderney Street, London, S.W., Analytical Chemist and Civil Engineer.  
Beaver, Chas. J., c/o W. T. Glover and Co., Salford, Chemist.  
Davis, Wm. A., Merton House, Braintree, Essex, Chemist.  
Douglas, Geo., Bowling Dyeworks, Bradford, Yorks, Dyer.  
Durant, H. T., Rand Central Ore Reduction Co., Box 1891, Johannesburg, S.A.R., Chemist.  
Pollak, Dr. Fritz, 12, Princess Road, Crumpsall, Manchester.  
Smith, James, 14, Mersey Road, Aigburth, Liverpool, Analytical Chemist.  
Turney, Fred. N., Whitemoor Leather Works, Nottingham, Leather Dresser.  
Wilson, E. Siddons, Arthog, Goddington Road, Strood, Kent, Chemist.

## LIST OF MEMBERS ELECTED 26th JULY 1897.

Berg, Julius, Elsaesischer Petroleum Gesellschaft, Godramstein, Pfalz, Germany, Oil Refinery Manager.  
Burland, Lt.-Col. Jeffrey H., 824, Sherbrooke Street, Montreal, Canada, Paper and Card Manufacturer.  
Dancer, Wm., 466, Chester Road, Old Trafford, Manchester, Analytical Chemist.  
Duckham, Alex., 40, Crooms Hill, Greenwich, S.E., Works Chemist.  
Eckford, Geo. S., Daere House, Arundel Street, Strand, W.C., Scientific Secretary and Chemist.  
Hunt, Edmund, 121, West George Street, Glasgow, Patent Agent.  
Skvortzoff, Basil N., Imperial Technical School, Moscow, Russia; and 33, Guildford Street, Russell Square, W.C.; Chemical Technologist.  
Wardle, Sir Thos., Leek, Staffordshire, Silk Dyer.

## CHANGES OF ADDRESS.

Bower, Frank, 10 Marylebone Road; Truman's Brewery, Spitalfields, E.  
Buck, C. A.; Journals to 521, Locust Street, South Bethlehem, Pa., U.S.A.  
Bunting, W. Lightfoot, 10 Hyde; Quarry Hill, Acerington.  
Christy, Thos., 10 Sydenham; The Manor House, Wallington, Surrey.  
Clarke, Goddard, 10 Ingleside; Fairlawn, 157, Peckham Rye, S.E.  
Cornish, Vaughan, 10 London; Franksome Cliff, Bournemouth.  
Crosfield, A. L., 10 Birkenhead; P.O. Box 1695, Johannesburg, S.A.R.  
Eastwood, Edw., 10 Wapping; c/o Lever Bros., Ltd., Port Sunlight, Birkenhead.  
Farrell, Frank, 10 Altrincham; 37, Crown Road, Great Yarmouth.  
Forth, H., 10 Regent Street; Langtry Grove, New Basford, Nottingham.  
Graham, W. H., 10 London; Sunnyside, Trowbridge, Wilts.  
Harris, H., 10 Singapore and London; Box 70, Vancouver, B.C.

Hogg, A. F., 10 Cliffe Terrace; 13, Victoria Road, Dartington; and Journals, until further notice, to 134, Birehauger Road, South Norwood, S.E.  
Jones, David S., 10 Transvaal; Wilson Terrace, Coatbridge, N.B.  
McGeorge, A. J., 10 New York; c/o Chesebrough Manufacturing Co., Delevan Street, Brooklyn, N.Y., U.S.A.  
McKillop, Jno., 10 Putney; 25, Primrose Mansions, Battersea, S.W.  
Matsui, G., 10 London; Sugar Works, Sakuranomiya, Osaka, Japan.  
Meisel, C. F. A., 10 Brooklyn; 402, Washington Street, New York, U.S.A.  
Pielsticker, C. M., 10 Harlesden; 15, Corinne Road, Tufnell Park, N.  
Poole, Herman, 10 Union Square; 323, West 34th Street, New York, U.S.A.  
Rae, Roderic H.; Journals to 113, Sotheby Road, Highbury Park, N.  
Read, E. J., 10 Bedford; 49, Aston Street, Ifley Road, Oxford.  
Reekie, J. A., 10 Glossop; Shaw Lane, Dinting, near Manchester.  
Rix, W. P., 10 Wimbledon; Ashfield Cottage, Liverpool Road, Newcastle, Staffordshire.  
Takayama, J., 10 Germany; retain Journals until further notice.  
Tasker G., 10 Glasgow; retain Journals until further notice.  
Waterhouse, Col. J., 10 Calcutta; Oak Lodge, Court Road, Eltham, Kent.  
Williamson, J. A., 10 Pitsea; 81, Cheverton Road, Upper Holloway, N.  
Willson, Thos. L., 10 New York; St. Catherine's, Ontario, Canada.  
Winser, P. J., 10 Greendale; The Acres, Bebington, near Birkenhead.  
Winstanley, Henry, 10 Hayfield; Chadswell, near Clitheroe, Lancashire.

## CHANGES OF ADDRESS REQUIRED.

Fogg, J., 10 11, Claude Villas, Grove Vale, East Dulwich.  
Wilkinson, Dr. S., 10 The Grove Co., Ltd., Marsh Gate Lane, Stratford.

## Deaths.

Hills, Henry, Chemical Works, Deptford, S.E. June 23.  
Hodgkinson, J. H., c/o E. Potter and Co., Dinting Vale, Glossop. June 21.

## PROCEEDINGS OF THE SIXTEENTH ANNUAL MEETING.

PRESIDENT: DR. EDWARD SCHUNCK, F.R.S.

The Annual Meeting of the Society of Chemical Industry was held in Manchester on Wednesday, July 14, in the Chemical Theatre of the Owens College. Dr. Edward Schunck, F.R.S., President of the Society, was in the chair, and the attendance, representative of all parts of the country, was large. At the opening of the proceedings the Secretary (Mr. C. G. Cresswell) announced that apologies for non-attendance had been received from Mr. E. Rider Cook (Hon. Treasurer), Sir Robert Pullar, Sir Henry Rosecoe, Mr. David Howard, Mr. R. Forbes Carpenter, Mr. G. N. Stoker, and Dr. Messel.

The minutes of the previous meeting, held in Carpenters' Hall, London, on July 15, 1896, were read, confirmed, and signed by the President.

## APPOINTMENT OF SCRUTATORS.

On the motion of Dr. Benj. H. Paul, seconded by Dr. J. Lewkowitsch, Dr. J. H. Bowman and Mr. H. C. Chaudan were appointed scrutators.

The President then declared the ballot closed.

## REPORT OF COUNCIL.

The Secretary read the report of the Council, which was as follows:—

We have the honour to report that the number of members on the register is 3,037, as compared with 2,971 at the last Annual Meeting. During the year, 226 new members have been elected, as compared with 237 last year; while the loss has been 162, as compared with 161 last year. Among the latter are 23 deaths:—J. M. T. Anderson, J. Ascongh, R. W. Peregrine Birch, Jos. Cunliffe, H. E. Dee, L. Demuth, R. Fulton, A. Goskirk, Josiah Hardman, Dr. Sydney J. Harris, Peter Hart, Dr. H. Kunheim, W. Martyn, A. H. Mason, Frank Mead, Jno. Molineux, W. A. Rowell, Fred. Scott, T. Shimidzu, A. J. Tyrer, G. M. P. Vary, Alex. Walker, and Jos. D. Weeks.

During the past session, 101 papers have appeared in the Journal, as compared with 92 last year. The excess of revenue over expenditure, as may be seen from the Treasurer's statement in the last number of the Journal, amounted last year to 1,011/ 3s. 11d., as against 162/ 3s. the year before.

This large difference is accounted for by the fact that various economies mentioned in the last Report have been effected during the year. There has been a reduction in most of the items of expenditure, the principal saving being in Journal expenses, both publishing and editorial. The increase in the receipts is, however, largely due to the amounts received as subscriptions to the Collective Index, which will be required when the index is published; so that there will not be such a large balance of revenue over expenditure at the end of the present year.

The production of the Collective Index has involved more labour than was anticipated. Experience gained during the progress of the work has necessitated partial recasting, to the great improvement of the index as an aid to research. The Council feels confident that on completion the delay in the production of the work will be justified.

The following chairmen of Sections retire this year:—Dr. John Clark (Scotland) and Mr. F. J. R. Carulla (Nottingham), and are succeeded by Mr. George Beilby and Mr. Jas. O'Sullivan. Mr. H. R. Procter retires from the secretaryship of the Yorkshire Section. His successor is not yet appointed. The Council acknowledges the debt of the Society to these gentlemen for their efforts on its behalf.

In the session of 1896 a committee of Parliament reported in favour of some amendment of the law in relation to the adulteration of food and drugs. In view of promised legislation, the Council appointed a committee to take such action at the proper time as might be found necessary to secure the Society's representation upon the Board of Reference proposed to be created by Parliament.

In October last a special committee was appointed to co-operate with the London Chamber of Commerce and other bodies in making enquiries as to what further concessions by the authorities in regard to the use of spirit were required in the interests of British manufactures. Several meetings of the joint committee were held, and eventually a conference took place with the officials of the Excise Department of the Inland Revenue, which it is hoped will have satisfactory results.

Dr. F. HURTER proposed and Dr. G. SCHLACK-SOMMER seconded the adoption of the report.

Dr. STEVENSON MACADAM said the report referred to the saving in expense in connection with the publication of the Transactions. He found that ten years ago the cost came to 13s. per page, but the figure had increased from that to 15s., then to 21s., and now it was 25s. per page of printed matter in the Transactions. There was a great increase in the expenses connected with the editorial department. As

to the publication department, he did not find such an anomaly. From first to last the expense had been almost exactly 30s. per page. He desired at the same time to draw attention to the anomalous position in which the Publication Committee stood towards the Society. He was quite aware that he could not take a formal motion on this matter because it was not till the 1st of July that he received a definite answer from the Council to the communication he submitted to them. The question he now raised had especially to do with the nomination, appointment, and retirement of members of the Publication Committee. He could not directly call the Publication Committee in question, because they were simply a branch of the Council, but he would say that the Committee should come more directly under the command of the Society itself. He wished to ask why such a rule as applied to the Council did not apply to the Committee. Of the members of the Publication Committee now acting he found that nine were members 15 years ago; of the Committee of 10 years ago there remained 11; and of six years ago, 23. No doubt they had rendered good service, but the effect was that the Committee was a standing committee and, practically, did not retire. Consequently the Committee was not properly responsible to the Society. He moved, as a recommendation, that the Council should devise rules whereby the nomination, appointment, and retirement of the Committee should be carried on on the same lines as the appointment, nomination, and retirement of members of the Council. This would enable them to get fresh blood on the Committee.

Mr. A. ERNEST POWELL seconded the motion.

Mr. THOS. TYRER said he thought Dr. Macadam and Mr. Powell were under a misapprehension. It was true that they had members of the Publication Committee who were old members. But he believed that in every Society provision was made for continuity. While, undoubtedly, the Committee should change, yet the change should be slow and steady. Committees were appointed annually by the Council, and the Council was responsible to the Society for their doings. Any matter of controversy was referred to the Council. The Publication Committee retired every year, but the attendances were called out before the re-election. Correspondence as to slip proof by a member of Publication Committee counted as an attendance. It would be monstrous to expect a man living in Glasgow always to come down to London. It was from communications of this character that very valuable amendments were often made. The point which Dr. Macadam had now so courteously raised was not that which he referred to the Council. With regard to the analysis of expenses, he was quite sure that a careful comparison of all the facts and figures would show that real economies had been made and that Dr. Macadam's criticism would not be upheld. They could not expect remuneration to remain stationary when the staff served them well and loyally. It was an invidious task to cut contributions down, but it had to be, and it was done most carefully. If, year by year, there was to be a competition for places on the Publication Committee, the work would probably not be as well done as it was now. Meanwhile, the Council would undoubtedly give consideration to what Dr. Macadam had said on both points.

Mr. F. J. R. CARULLA pointed out that the pages of the Journal contained nearly double the matter of the first six volumes.

Dr. S. MACADAM said he would be satisfied if the Committee were elected in the same manner as the Council, but he was in the meantime content to accept the assurance of Mr. Tyrer. All he asked was that his recommendation should appear in the Journal, and on that understanding he withdrew it.

The report was then adopted.

## TREASURER'S REPORT.

In the absence of the Honorary Treasurer the report was read by the Secretary. It has already appeared in these columns. On the motion of Mr. T. Fairley, seconded by Mr. H. Brunner, the report was adopted.

The President then delivered the following address :—

#### PRESIDENT'S ADDRESS.

Some years ago a meeting was held within the walls of the building in which we are now assembled for the purpose of forming a society for the promotion of technical as distinguished from scientific chemistry. The Society was then founded and its general scope and object were defined: the name it now bears, that of the Society of Chemical Industry, being at the same time given it. I was present at that meeting, and made a little speech in favour of its object. I may therefore be considered in a sense one of the founders of the Society. In subsequent years I was unfortunately not in a position to attend the meetings of the Society or its sections, nor to assist at its deliberations, but I have always followed the record of its proceedings and its progress with interest. The history of this Society has been in all respects one of continuous success, as may be seen by anyone looking over the 15 volumes of the Journal in which our achievements are recorded.

In taking such a retrospect, one thing, I think, must strike everyone; that is, the high tone assumed by the Society and reflected in its Journal, the entire devotion to the objects for which it was established, the total absence of laudatory or depreciatory criticism as regards new inventions, the intension so conspicuously shown of only imparting useful information on chemico-technological subjects. These qualities have given our Society, in my opinion, a distinguished position in the technological world. That this position may for many long years be retained is my earnest wish.

In looking at the list of past Presidents of the Society, as given in our Journal, it will be seen how many eminent men have held the post, and on examining the reports of our annual meetings how valuable and interesting were the addresses delivered by them. When therefore I was informed of my nomination as President for the past year I was taken by surprise and felt something like dismay, as being very conscious of my inability, should I be elected, to follow the example of my predecessors in performing the duties attached to the office, and more especially in adding another to the able addresses which adorn our Journal. It would have been useless to refer to the fact that I am no longer in touch with the advanced chemical technology of the day; the reply might have been: Do your best, which is indeed the utmost any man can do under any circumstances. A more valid reason for refusal might have been found in my advanced age, which was likely to prove, and I am afraid has proved, a serious drawback to my activity. It would, perhaps, have been to the advantage of the Society, and certainly so to mine, had I been appointed to the high office I now hold 10 or more years ago, when my faculties were I will not say at their prime, but certainly brighter and more fitted for hard work than they are at present. We read of the Psalmist's three score years and ten as the limit beyond which the bodily and mental powers of man cease to show any vigour. The Government of this country discharges its servants at the age of 65, at which age they are supposed to be superannuated. And yet a scientific society does not hesitate to bestow an office involving some mental and bodily exertion on a man of more than 75. I do not complain of this, being too sensible of the great honour that has been conferred on me. I mention the circumstance merely as bespeaking your indulgence for any mistakes and shortcomings I may have been guilty of during my term of office.

The delivery of an address by the President on this occasion being a *sine qua non*, the question arose with me as to what the subject should be. I might imitate the example of some of my most distinguished predecessors, such as Sir H. Rose, Sir F. Abel, Mr. Weldon, Dr. Mond, Sir Lowthian Bell, and last but not least, Mr. Tyrer, my distinguished predecessor, who have all given us in the form of addresses valuable and exhaustive treatises on the subjects with which they were specially familiar. The question may be asked, Why not go and do likewise? I would willingly have done so, but, alas, the speciality which I may or might have called my own—the chemistry of organic colouring matters—has sailed away far out of my

reach and ken, and would not, I fear, have been overtaken except after arduous labour, and then what I might have to say on the subject would probably have done little to extend it.

Instead, therefore, of giving you an elaborate disquisition on any particular subject, I shall rather endeavour to divert you by referring in the first place to some forgotten or half forgotten facts connected with the history of chemical technology in the Manchester district during the first half of this century, more especially in connection with the personalities of the men to whom we owe so much in this branch of industry. I shall, in the next place, refer shortly to a few organic colouring matters about which I think I know as much as most men; on which will follow a few remarks on the theory of dyeing as applied to cotton, and some general observations on the dyestuffs of modern times as compared with those formerly employed; and lastly, some views and opinions on some subjects on which I have thought, but which I do not profess to have studied in a manner such as their importance would demand.

#### *Facts and Reminiscences relating to the History of Chemical Industry in Manchester during the First Half of the Century.*

I think it may be of interest to the members if I were to recall some facts, partly known to myself, partly due to information derived from others, regarding the history and achievements of some persons living and flourishing during the first half of the century in our town and neighbourhood to whom chemical industry is more or less indebted. I begin with John Dalton. I suppose there is no one here present but myself, and very few persons still living, who were personally acquainted with this great man. On my mind his image is so indelibly impressed that, were I a portrait painter, I think I could trace out his lineaments to the minutest feature; though this might not be very difficult, since the expression of his face, though fine, was remarkably passionless.

Dalton lived with the master of the school that I attended, and I had frequent opportunities of seeing and wondering at his ways. How well I remember his peering every morning out of his bedroom window, which opened on to the school yard, and looking at his thermometer outside, the bulb of which was shaded by a card—a circumstance which puzzled me very much at the time. Very soon after he would appear at the front door of the house arrayed in his sun-coloured Quaker dress, with knee breeches and broad-brimmed hat, stooping, as most thoughtful men do, with a large lantern in his hand, with which he proceeded across the street to his laboratory in the building belonging to the Literary and Philosophical Society. His object in carrying the lantern was to light the fire in his laboratory—matches, except of the rudest description, being then unknown. His laboratory was a room the dimensions of which did not exceed 20 ft. by 15; here all his great discoveries were made, and here I suspect all his works were written, there being no room in the house where he lived in which he could well be alone to compose his writings. I was often puzzled in after years to know how, in the contracted room he used for his laboratory, and which still exists, though used for other purposes, he could make those world-wide discoveries on which his fame depends. The answer to the puzzle was, however, simple enough: it was the mind that made the discoveries, not the place. I mention Dalton first and foremost, not so much on account of his great chemical discoveries, but because he was, in his day, the universal referee in all matters connected with technical chemistry, such as the purity of waters used for dyeing purposes, the genuineness of drugs, &c. He was on intimate terms of friendship with Thomas Hoyle, the eminent calico-printer of this town, also a Quaker—a friendship of which religious sympathy and association probably formed an element; and it is just possible that Dalton may have had some share in the development of the process whereby the production of the so-called Hoyle's purples on calico was brought to the high state of perfection such as we know it, but there is no evidence I know of in support of this view.

A very eminent family connected with chemical industry flourished in Manchester at the same time as Dalton. I allude to the Henry family. Of this family three gene-

rations successively distinguished themselves. The first member of any note was Thomas Henry, a gentleman, it is understood, of Irish extraction. He was the first to prepare the so-called "Henry's magnesia"—a compound of the virtues of which the discoverer, or rather the preparer, entertained somewhat exaggerated conceptions, going a little beyond what its merit as a useful medicine justified. The distinctive merit of Henry's magnesia, I have always understood, consisted in this, that when stirred up in water it formed a soft, milk-like emulsion in which no grittiness was perceptible, and which gave no deposit, even on long standing; and this property, I have been told, was due to precipitation with potassium carbonate in the place of sodium carbonate, and to using the solution of magnesia in a very concentrated state—a proof, if correct, of how often success in manufacturing manipulation depends on minute details. A favourite practical joke in Mr. Henry's works was to ask a lady visitor to lift up a huge block of magnesia, weighing apparently a hundredweight; she, exerting herself to her utmost, would be surprised to find that it could be lifted like a bundle of feathers. In addition to magnesia, Mr. Henry manufactured aromatic vinegar, an article without which no lady's toilet table was thought to be complete in those days. By the manufacture of these two articles it is supposed that in the course of years a large fortune was amassed. That Thomas Henry was a man of some culture may be seen by his paper "On the advantages of Literature and Philosophy in general, and especially on the consistency of Literary and Philosophical with Commercial Pursuits," published in the first volume of the memoirs of the Manchester Literary and Philosophical Society. I cannot help thinking that the class of men to which Mr. Henry belonged—men who combined an assiduous attention to professional duties with a considerable amount of general culture—is gradually becoming less numerous. If this be indeed the case, we can only look back and regret what is past and gone. No doubt the present has, and the future will have, much to compensate us for what we have lost—still, what is lost is gone, and can never return. Thomas Henry was succeeded by his son William Henry, who had enjoyed the advantages of a university education, but continued nevertheless to carry on the business of a manufacturing chemist. William Henry took a great interest in theoretical chemistry, and was the author of a work entitled "The Elements of Experimental Chemistry," which ran through several editions and had much vogue in its day. In one of the early editions of this work the author says, referring to the plan of a chemical laboratory: "It is scarcely possible to offer a plan of a laboratory which will be suitable to every person and to all situations, or to suggest anything more than a few rules that should be generally observed. Different apartments are required for the various classes of chemical operations. The principal one may be on the ground-floor, 25 ft. long, 14 or 16 wide, and open to the roof, in which there should be contrivances for the occasional escape of suffocating vapours. This will be destined chiefly for containing furnaces, both fixed and portable. It should be amply furnished with shelves and drawers, and with a large table in the centre. Another apartment may be appropriated to the minuter operations of chemistry, such as those of precipitation on a small scale, the processes that require merely the heat of a lamp, and experiments on the gases. In a third, of smaller size, may be deposited accurate balances and other instruments of considerable nicety, which would be injured by the acid fumes that are constantly spread through a laboratory." I quote this passage in order to show the wide difference there was at that time between the well-appointed laboratory of the private amateur and the humble apartment in which Dalton's great discoveries were made, and in which the atomic theory first saw the light. In one of the earlier editions of his "Elements of Chemistry" Dr. Henry gives a list, with plates, of all the various apparatus necessary for carrying on chemical operations. The list is very extensive, but singular to say does not include one of the most ordinary pieces of apparatus—one with which every beginner is familiar—I mean a stand of test tubes. To what this is to be attributed, whether to oversight, or to the fact that in those days the attention of chemists was

directed more to experiments with gases and the results of igneous fusion than to reactions in the wet way, it is hard to say. To Dr. William Henry is sometimes given the credit of the invention of aerated waters. There is some doubt about this, but if correct, he must be numbered among the benefactors of mankind, as having added largely to its innocent gustatory pleasures. A third generation of this remarkable and highly-gifted family was represented by Dr. William Charles, son of Dr. William Henry. Dr. William Charles Henry was a tall, dignified person of polished—one might say aristocratic—manners and bearing. He had passed through the regular medical course of the Edinburgh University, and practised as a physician in Manchester. He gave up his practice, however, and devoted himself to commercial pursuits in connection with the works belonging to his family. I have good reason to remember Dr. Charles Henry, for, he hearing that I was learning chemistry entirely from books, very kindly offered to give me some practical instruction in science, and I was accordingly introduced into the laboratory attached to his works—a somewhat dark and dingy apartment, but a paradise to me who had never seen its like before—and taught the rudiments of analysis. Dr. Charles Henry was a favourite pupil of Dr. Dalton, who bequeathed to him the whole of his scientific apparatus. This was afterwards given to the Literary and Philosophical Society, in whose rooms it is still to be seen. He also wrote a life of Dalton, a classic production forming one of the most important volumes of the Cavendish Society's series.

An eminent contemporary of the Henrys and belonging to the same class, *i.e.*, of men distinguished not only for skill as manufacturers, but also for general culture and taste, was James Thomson of Primrose, near Clitheroe, head of the firm of calico-printers called after him. The history of calico-printing in this country has still to be written, but when it is written the name of James Thomson will occupy a conspicuous position in it. He was a man of wide culture and had an extensive library; a man of science also, with a large, well-furnished laboratory. In Thomson's time very little had been done to elucidate the theory of dyeing. Dyeing and calico-printing were in this country considered mere arts to be classed with wall painting and decorating. In France, however, much had been done through the labours of Berthollet, but more especially of Chevreul, to place the art of dyeing on a scientific basis, and establish the principles on which it depends. Thomson was, no doubt, acquainted with their works, and, carrying out their ideas, was able to effect great improvements in the art which he cultivated. He will always be remembered as the inventor of the process for discharging Turkey-red by printing tartaric acid on the cloth and then passing it through a solution of bleaching powder—a process which, I believe, is still in operation. This process was a great improvement upon the press-plate printing as carried out in Scotland and brought to perfection by Montgith, of Glasgow, in 1818. Thomson's large-mindedness was shown by his calling to his aid men of scientific distinction, such as the present Lord (then Dr.) Playfair, an eminent pupil of Liebig. Mr. Steiner, who afterwards distinguished himself by his improvements in Turkey-red dyeing, was also with him for some time. We, therefore, can hardly feel surprised when we are told that the Primrose Printworks were everywhere celebrated for their productions, though I am not aware that they were noted for any speciality with the exception of the process just mentioned. Mr. Thomson was the first to give a drawing of the cotton fibre as it appears under the microscope in his memoir on the "Mummy Cloth of Egypt," in which he arrived at the conclusion that the cloth consists entirely of linen, and that cotton was probably unknown to the Egyptians. Most ancient fabrics consisted, I imagine, of wool only; this was the case with some coloured fabrics belonging to quite a late period of Egyptian history, which I examined some time ago. Thomson's social position enabled him to be of assistance in passing measures of public utility. He was of great service in helping to pass the Copyright of Designs Bill, and he was a great supporter of the Manchester School of Design.

The name I have now to mention is that of a man of a type differing widely from that of James Thomson and the

Henrys—it is that of John Mercer, probably the greatest genius who ever applied himself to the improvement of calico-printing. Born in the humblest circumstances and without even the rudiments of learning, he taught himself all he required, from reading to music, mathematics, and chemistry, and by his industry and ingenuity raised himself gradually from the position of a handloom weaver to that of a partner in an important calico-printing firm. Mercer's inventions in connection with calico-printing are characterised by great originality and by the ease with which they could, it seems, be carried out at once in practice. Coming as they did from one who was entirely self-taught and had read but few books on chemistry they are indeed marvellous. To name them all would take more time and space than I have at my disposal. They are described at length in Parnell's "Life and Labours of John Mercer," an excellent work which is unfortunately out of print. Among the inventions due to Mercer the following may be held to be the most important: The application of the orange-coloured sulphide of antimony and of the brown oxide of manganese in calico-printing, his improvements in Turkey-red dyeing, the successful attempts to replace the crowding previously used in calico-printing by substitutes such as sodium phosphate or arseniate, and last though not least, the invention of a process, now called "mercerising," whereby the properties of cotton fibre, both chemical and physical, are modified in a remarkable manner. This process of mercerising, which consisted in passing calico or any other cotton fabric through a strong solution of caustic soda, showed, like everything that Mercer did, much ingenuity and originality, but it did not come into such general use in Mercer's time as he had expected, partly, I understand, because the dyes of his day were not of a kind to withstand the energetic action of the alkali. Latterly, however, it has again come into use as a means of producing a peculiar corrugated or crinkled effect on calico, and its employment for this purpose has assumed, I am told, quite extraordinary dimensions. Its use as a means of imparting to cotton a silk-like lustre has been described in a paper read before the Yorkshire section during last session. Mercer, with his manifold mental activity, did not confine himself to subjects connected with the arts of dyeing and printing, he also speculated and always with ingenuity on subjects belonging to pure chemistry. He paid attention to so-called catalysis, to the composition of bleaching powder, and to the relations between the atomic weights of the elements. On the last-named subject he was probably the first to put forth more or less speculative opinions, such as were subsequently developed by Newlands, Mendeleef, and others. Whatever he said, whatever he wrote, was characterised by ingenuity and originality, truly one of nature's own original geniuses. I knew John Mercer. I always associate him in my memory with Sam Bamford, the Radical, whom I also knew, both Lancashire men of the best type, of robust bodily frame, thoroughly honest and outspoken, without guile or deceit, gentle and devoid of suspicion. May the type never die out!

The next name I have to mention is that of Mr. John Dale. His name brings us down to comparatively recent times, when new substances and new methods were being introduced into manufacturing chemistry. In the transition period through which chemical technology then passed Mr. Dale bore a conspicuous part. Mr. Dale was a native of Birmingham, but he came to Manchester early and spent here the greater part of his life. Arrived in Manchester he became a pupil of John Dalton, but in his case, as in that of most of Dalton's pupils, no characteristic anecdote or trait of the master seems to have come to us through him. After passing through various employments, that of taking charge of some calico-printworks being one, he settled down at last as partner of the noted firm of Roberts, Dale, and Co., of this city. It was in connection with this firm that the greater part of his work was done. The manufacture of oxalic acid by fusion of sawdust with caustic alkali in accordance with Gay-Lussac's invention was one of the first processes carried out practically by Dale. Then followed improvements in the manufacture of mauve, the preparation of Manchester Brown, and Manchester Yellow,

after which came the manufacture of aurin, the theory of which was worked out by the late lamented Professor Schorlemmer in conjunction with Mr. Dale's son. Mr. Dale is the author of what is probably the best method invented so far of estimating the quantity of colouring matter contained in commercial indigo. I knew John Dale well and was always impressed when conversing with him, with the originality of his views and the simple unaffected manner of his expressing them.

In this place I might mention the name of Mr. Peter Hart—a valued member of our Society quite recently deceased. He was for many years connected with the firm of Tennant, Clow, and Co. They manufactured salts of tin, sulphates of copper and zinc, nitrates of lead and iron, sodium arsenate, and sulphate of indigo.\* Dr. James Young, afterwards celebrated for his inventions in connection with the mineral oil industry, was for nine years with Messrs. Tennant, Clow, and Co., and introduced the manufacture of red prussiate of potash. The chief part of Mr. Young's career was, however, spent in Scotland.

I now propose to transgress somewhat the limits I had set myself in bringing before you this subject—the early history of technical chemistry in this district by referring to men who are still amongst us and to processes still in operation. Many years ago Mr. E. Sonstadt, who was associated with the late Walter Weldon in scientific and literary undertakings, was struck by a remark of Bunsen in one of his memoirs, that if the metal magnesium could be produced on anything like a considerable scale it might be found possible to obtain photographs in dark and obscure places. Mr. Sonstadt, struck with this suggestion, resolved to try to produce this metal. In due time his experiments were successful, he having devised the well-known process of obtaining magnesium by the decomposition of the double chloride of magnesium and potassium by means of sodium. It was found at first that much of the magnesium so obtained was in tiny globules interspersed among the mass. In order to obtain it in a more concrete form he devised an ingenious process of distilling the metal, which was found to work satisfactorily. Almost the first specimen of magnesium produced was shown to Michael Faraday, who was highly pleased with it, exclaiming, "This is a triumph, this is a triumph!" It was suggested that he should accept the specimen for his own collection, but he with characteristic modesty declined, saying, "If you will allow me I would like to present it to the Royal Institution in your name." In due course works were erected in Salford and the manufacture of magnesium commenced on a large scale, conducted under the care of Mr. Samuel Mellor, who has been associated with them ever since. The manipulation of magnesium was attended by many difficulties, as it would neither roll into sheets, draw into wire, nor be beaten by the hammer on the anvil into shape. After many trials and experiments, however, Mr. W. Mather of the Salford Iron Works, devised a highly ingenious machine for forcing it into wire of any thickness or fineness. This machine has never been superseded and remains to this day a specimen of the inventor's great mechanical ability. The suggestion that magnesium could be utilised for taking photographs in dark and foggy weather was very soon carried out, Mr. A. Brothers, of this town, being the first to make use of the metal for photographic purposes. For signalling purposes, too, it was found that magnesium could be utilised. In the Ashantee War, Captains Bolton and Colomb devised a clever method of signalling, words being spelt out by lights of longer or shorter duration, in which magnesium was used in the form of dust or powder mixed with kauri gum or lycopodium. For fireworks and signal rockets also, magnesium came to be extensively used.

After Messrs. Bell Bros., of Newcastle, had abandoned the manufacture of aluminium, all the sodium consumed in England and almost all over the world was produced in this district, and so arose another local industry. Potassium was produced at the same time. A curious incident, which occurred in the early period of the manufacture of these metals, may here be recorded. A rather large quantity of

\* Garancine—an article no longer in use, made by the action of sulphuric acid on madder—was also manufactured by this firm.

potassium and sodium having to be sent to a German professor, the two metals were put into the same vessel to save room. When the parcel arrived at its destination, singular to say the metals were no longer separate and solid, but had combined to a liquid alloy like mercury. This formation of a liquid alloy of potassium and sodium explains the fact that potassium obtained from so-called pure salts, but still not quite free from sodium, is more or less liquid, causing great annoyance to the manufacturer. It is not likely that this curious compound will ever be examined, as it has extremely explosive properties.

The history of the discovery of vanadium in this district, is one of peculiar interest. Some 25 years ago in the neighbourhood of Mottram and Alderley, Cheshire, some mineral deposits were found—I presume in the red sandstone—containing copper, cobalt, and other metals; and works were erected there for obtaining these metals, under the care of Dr. Gerland, an esteemed member of our Society. While working with this material, Dr. Gerland, obtained a blue liquid, from which no copper was precipitated by zinc. On examination, the blue colour was found to be due to some compound of vanadium. In consequence of this interesting discovery, a quantity of raw material was collected at the original site and at another site near Shrewsbury, and with the assistance of Mr. Mellor, of the Magnesium Metal Co., this was worked up and brought into a state of comparative purity. With this material to work on, Sir Henry Roscoe was enabled to carry out his classic researches on vanadium and its compounds. It also proved of great use in the hands of Mr. John Lightfoot who was then engaged in an investigation of aniline black, and who found vanadic acid to be far the best agent to use for the production of that dye. The material thus obtained was sufficient to supply all the vanadium salts used in commerce for a number of years.

I come now to the second division of my address, referring to—

#### *Organic Colouring Matters.*

Of these it is principally the natural colouring matters, *i.e.*, those occurring in nature, that I shall allude to; and of these, too, I shall refer to only a few—such, namely, as I have specially studied and am familiar with. I will begin with chlorophyll. This substance, to which the green colour of leaves and other parts of plants is due, is certainly, in some way not yet understood, involved in one of the most important functions of vegetable life—that of the conversion of the  $\text{CO}_2$ ,  $\text{NH}_3$ , and  $\text{H}_2\text{O}$  of the atmosphere and soil into organic matter. Chlorophyll is one of the most fugitive of substances. Under the action of air and light, it is rapidly destroyed—this seems, indeed, to be always its fate, not only outside, but also within the vegetable organism. When, however, it is submitted to the influence of strong chemical agents, it yields, singular to say, products of remarkable stability, a fact of which our present vegetable chemistry fails to give a satisfactory explanation. Whether mineral acids or whether alkaline lyes are employed, the result, so far as stability is concerned, is the same. When submitted to the action of strong acids, chlorophyll undergoes complete decomposition, yielding definite products, to one of which, and the most important, the name of phyllocyanin has been applied. This substance, when in alcoholic solution, resists the action of air and direct sunlight for weeks, whereas an alcoholic solution of chlorophyll would, under the same circumstances, very soon lose its colour and be decomposed. Phyllocyanin yields compounds with metallic oxides of a brilliant green colour, which are at the same time remarkably stable. Of these compounds the most remarkable, so far as regards brilliancy of colour, is that with copper. This compound might, I think, on account of its great stability, be used with advantage, when properly prepared, in painting, more especially water-colour painting. When employed in the representation of foliage, for which it would seem well adapted, it would require the admixture of a yellow pigment, since the natural colour of leaves is due to the mixture of a green with a yellow colouring matter, the varying proportion between the two giving rise to the variety of tints we see in spring and summer foliage. The brilliant autumnal coloration of some leaves is due

to quite a different class of substances. Chlorophyll, so called, is used, I believe, as a means of imparting a green colour to a particular class of soaps, but why a green colour should be required in this case, and why any other green pigment should not answer as well, I cannot understand. It occurs in commerce as a dark green syrupy mass under the designation "chlorophyll purissimum." It is, however, neither purum nor purissimum, nor even chlorophyll at all, being a mixture of fat with some derivative of chlorophyll, such as cupric phylloeyanate or the product of the action of alkalis on chlorophyll, which, like phylloeyanin, is a very stable body, and has a fine green colour. How these substances are applied in soap-making, I have never been able to ascertain. It may be asked whether chlorophyll, communicating as it does such a brilliant green colour to vegetable tissues, might not be employed for dyeing fabrics the same colour. I have myself made some experiments in this direction, but without any conspicuous success. The insolubility of chlorophyll in water and its great instability present obstacles to its employment in this way, which are almost insuperable. In my experiments I used the cupric phylloeyanate, which is prepared by decomposing chlorophyll with hydrochloric acid, collecting the resulting product, dissolving it in boiling glacial acetic acid, and adding cupric oxide, when a liquid of a splendid bluish-green colour is obtained, which, on cooling, deposits crystals of a fine cuprous lustre by reflected light. This compound, of which acetic acid is in reality an essential constituent, was dissolved in acetic acid, and bits of wool, silk, and cotton, sometimes prepared previously with albumin, were dipped in the solution and left to lie some time, then taken out, exposed to the air, and washed. The result was the production on the tissues of various shades of green according to the fabric used, but the tone was anything but brilliant, and in these days when brilliancy rather than solidity is sought for, such a colour would not be of much value. Some doubt might arise as to whether this imparting of green colour to fabrics is in reality a dyeing process in the true sense, or whether it is not rather a depositing of a pigment on the fibre in consequence of the evaporation of its solvent. It would resemble the green colour formerly much used in calico-printing, which was made by dissolving chromium arseniate, which is a compound of a pale sea-green colour, in hydrochloric acid, then printing on the calico and exposing to air; the solvent escaping, the compound was left fixed on the fibre. However, this is a matter of academic interest only.

This brings me to the subject of pickles, comparatively a not very dignified subject, but still not unimportant as everything is that concerns articles of food in daily use. Much discussion has of late arisen as regards the real or supposed injurious consequences of imparting to pickles and other articles of food the much admired vivid green colour so often seen in them. Since the points to be considered are connected more or less with the chemistry of chlorophyll it can hardly be expected that the public in general, perhaps not even the majority of medical men, whether analysts or not, can arrive at correct conclusions on the matter. The opponents of the so-called adulteration says this: the bright green colour so frequently seen in pickles is communicated by the addition of some salt or compound of copper, now copper compounds are poisonous, therefore the colouring or dyeing of vegetables by means of copper in any shape must be injurious. To this it may be replied that copper salts taken internally are no doubt injurious, even poisonous, though probably far less so than compounds of some other metals. The practical question to be determined however is whether the quantity of copper actually present in the coloured articles is really as injurious as has been represented. The green colour seen, say in a pickled gherkin, after the addition of some compound of copper is that of a derivative of chlorophyll, it is that of cupric phylloeyanate, the compound already referred to, which has a considerable tinctorial power. If we consider how little chlorophyll most vegetables contain, probably not 1 per cent. that chlorophyll yields by decomposition a not very large amount of phylloeyanin and that the cupric phylloeyanate contains according to my determination only 9 per cent. of copper, and when we consider moreover that the copper is contained in

the cuprie phylloeyanate in a form in which it cannot be detected by ordinary reagents, then I think we may arrive at the conclusion that the small quantity of copper contained in a green pickle or vegetable cannot be very injurious; it probably does not exceed the amount we are supposed to swallow daily with our food. The mischief, however, consists in this, that the pickling vinegar containing usually an excess of copper salt is allowed to stand in contact with the pickles and may be consumed to some extent with the latter. If the vinegar is poured off and the vegetable washed with water, which is also poured off before adding fresh vinegar, then I feel convinced any quantity of the product may be eaten with impunity. An eminent physiological chemist, Prof. Tschirch of Berne, who has undertaken an exhaustive examination of the subject, has arrived at a similar conclusion. From his experiments, which agree with those of others, it follows: 1. That copper, or rather the salts of copper, are by no means innocuous as has sometimes been asserted, but that a tolerably large dose is required in order to produce injurious effects. 2. That for a human being weighing 60 kilos, the quantity of copper that may with safety be taken per day amounts to 0.1 gm. 3. That as regards the artificial green coloration of vegetables with compounds of copper 50 mgrms. of copper may be allowed to 1 kilo. of vegetable without fear of any injurious consequences.

These are precise and definite conclusions derived from accurate experiments, and I cannot conceive what objection there can be to establishing in this case the exact percentage beyond which the adulteration, if it may be so called, shall go, and so avoiding the unseemly disputes which sometimes take place in courts of justice between those who maintain that cupric compounds being poisonous should on no account be permitted in the preparation of food, and those who assert that the use of such compounds may, to a certain extent, be allowed. All that need be ascertained in any doubtful case would be whether the limit in regard to the amount of copper is transgressed or not. For the information of those to whom this view of the matter is not acceptable, and who still feel anxious about copper in food, I may say that all pickles—that is, pickled vegetables—that show a grass-green colour, however slight, certainly contain copper. I lately bought a bottle of gherkins of a pale grass-green, prepared according to the label by a first-class firm in London, and "warranted free from copper," but notwithstanding the assurance given they did contain copper. Pickles prepared with vinegar only are always and without exception olive-green. For my part I quite fail to understand the pleasure and satisfaction derived from the eating of a bright green article of food. An olive-coloured gherkin, if well prepared, is quite as toothsome as a bright green one; I am inclined to think more so. Should a substitute be required for the copper salts hitherto employed in cooking, which shall be both bright and innocuous, I think it might easily be found among the numerous green colouring matters of artificial origin now occurring in commerce. So much for the industrial applications of chlorophyll.

Before leaving the subject of chlorophyll, I should like to say a few words relating to an important discovery connected with the chemistry of chlorophyll. This discovery was made in my laboratory, but the merit of it is chiefly due to my esteemed friend and former collaborator, Dr. Marchlewski. The discovery is not of importance from an industrial point of view, though one can never tell what the future may bring forth, the mere scientific curiosity of one age sometimes becoming the basis of an important industry in the next. From another point of view the discovery is both interesting and important, and I will therefore shortly describe it. By the action of strong acids on chlorophyll a certain product is obtained, and the action of alkali on this product, in sealed tubes, leads to the formation of phylloporphyrin, a substance crystallising in lustrous red needles which has remarkable properties. Treated in a similar manner, hæmoglobin, the colouring matter of blood, yields an analogous substance—hamatoporphyrin. Now these two substances, phylloporphyrin and hamatoporphyrin, resemble one another in several respects in a most remarkable manner. Both are red in colour and give red solutions; both act the part of weak bases towards strong acids; both when heated give off fumes of pyrrol; the ethereal solu-

tions of both show absorption spectra of seven bands, the intensity and relative position of which are in both cases absolutely the same, the only difference being that in the case of hamatoporphyrin the bands are slightly nearer the red end of the spectrum (see page 595). As to composition too, the two substances approach one another, that of phylloporphyrin being expressed by the formula  $C_{56}H_{18}N_4O_8$ , that of hamatoporphyrin, according to Nencki, by  $C_{16}H_{18}N_4O_8$ ; they differ therefore in the amount of oxygen they contain, phylloporphyrin, as might be expected, having the least.

I might speculate at some length on the resemblance thus shown to exist between a derivative of chlorophyll, that most important substance in the vegetable economy, and an analogous derivative of hæmoglobin, which is a substance equally important in the animal system, but I refrain. Prof. Nencki, an acknowledged authority on the subject of blood colouring matters, referring to the discovery I have just shortly described, says it may throw some light on the process of evolution which the chemical constitution of organised structures has undergone in former ages, the development of the material of which these structures consisted having gone on *pari passu* with that of their form and structure, but I do not venture to follow him on this domain.

There is another subject connected with the chemistry of plants with which I am tolerably familiar, and on which I wish to say a few words, seeing that it is not, generally speaking, well understood; it is the nature of the process whereby the well-known blue colouring matter, indigo, is formed in and obtained from the tissues of certain plants. Many years ago I made a series of experiments which led to the conclusion that the organs, particularly the leaves, of indigoferous plants contain a peculiar substance, a glucoside, which, when exposed to the action of certain reagents, particularly acids, splits up, yielding indigo and a kind of sugar, with other products of no special interest. This substance I called *Indican*, and I succeeded, approximately at least, in determining its composition, so far as to enable me to explain the way in which it is decomposed under the influence of acids. The matter is, however, not quite so simple as at first sight it might appear. Indican, like chlorophyll, seems to retain, if one may say so, some of the susceptibility belonging to its vital organic origin. It is decomposed, so to say, by a mere touch. It is not a matter of indifference, however, by what agent it is influenced; acids produce one effect, alkalis a totally different one, and this in the presence even of small quantities of these reagents. If an aqueous solution of indican is boiled, then mixed with acid, and then boiled again, indigo-red is obtained in place of indigo-blue. If the solution is heated with the addition of alkali, then, on adding acid and boiling, brown resinous products are formed bearing no resemblance to and having apparently no connection with indigo. In every case, however, the resulting products, unlike the parent substance from which they are derived, possess a remarkably stable character, in this respect resembling the products derived from chlorophyll. All this has been clearly set forth in various papers published in the Memoirs of the Literary and Philosophical Society of Manchester. It is therefore somewhat surprising to find men of science, who in treating this subject, go on babbling away on the old lines as if nothing had been done therein during the last 50 years. A German chemist complains of not being able to find a certain paper on account of its being buried in the huge catacomb of the Philosophical Transactions. The Memoirs of the Manchester Literary and Philosophical Society might perhaps be called a cemetery, certainly not a catacomb, and comparatively very little labour therefore would suffice to enable anyone to disinter what lies buried there.

A German chemist named Molisch professes to have discovered that the process of formation of indigo in the aqueous extract of indigoferous plants is one of fermentation, and that it is the presence of a certain bacterium that is the immediate cause of decomposition. In former days it was electricity that was called in to explain anything we did not understand, now-a-days it is fermentation and a bacterium or bacteria. In this case the

baacterial hypothesis is, I believe, without foundation. It is possible, of course, that in the experiments of Molisch the bacteria did indeed cause the formation of indigo, but only, I believe, in consequence of the secretion of some acid, or other substance by the bacteria. The weakest acid will do this, but I have shown that even in the absence of any acid, indican is decomposed under a variety of circumstances in which spontaneous decomposition can alone account for the change. If, for instance, the leaf of an indigoferous plant be exposed under water to a temperature below freezing, the parts of the leaf that become frozen turn blue, the indican being decomposed, while the parts not frozen remain green and unchanged. A leaf immersed in cold spirits of wine, turns partially blue in like manner. Here there can be no question of bacteria; for what bacterium can live and act in ice or spirits of wine? All the facts described seem to me to be easily explained without calling in the aid of bacteria or any extraneous agency. Indican, the glucoside of indigo, is a body of extremely unstable character, so much so that if only left to itself at ordinary temperatures it undergoes spontaneous decomposition. In the vegetable cell it is only preserved from decomposition by the vitality of the cell, destroy the vitality by cold, mechanical injury or chemical agency and the indican is decomposed.

Messrs. Darwin and Meldola have recently (*Nature*, Nov. 12, 1896) given an interesting account of the manufacture of indigo from woad, which is still carried on in a remote corner of Lincolnshire for the use of the woollen dyers of Yorkshire. These observers say that the process they describe consists in a "zymolytic decomposition of glucosides." This is, however, mere hypothesis. By a series of well-conducted experiments carried on in the indigo manufactories of India, Mr. Bridges-Lee\* has proved that there is no particular indigo-producing process of fermentation whatever. He states as the result of his experiments that "there is no special distinctive kind of fermentation for the indigo plant, so far as I have been able to discover by careful observation and very numerous oft-repeated experiments. The indigo plant, like nearly every other kind of green plant, will rot if left in water long enough, and while rotting it will give rise to all sorts of foul offensive products of decomposition, and like other rotting plants will give off foul smelling gases, but at no stage is there any specially distinctive kind of fermentation apart from progress on the road to decomposition and decay, i.e., there is no fermentation of a kind corresponding to the alcoholic or acetic or butyric fermentation." I fully endorse all that Mr. Bridges-Lee says on this subject, as it is quite in harmony with what I have always maintained.

Indigo-blue, as all chemists know, has been produced artificially by Bayer and others, and hopes were at one time entertained that the natural product would be replaced by some artificial one, but these hopes were not, and under prevailing conditions could not, be realised. Indigo, considering the large percentage of colouring matter it contains, is one of the cheapest of dyestuffs, and in order to replace it by an artificial product, a very cheap material to begin with, and a simple inexpensive process of manufacture would be required. Improved processes applied to the treatment of the indigo plant in India might, moreover, lead to a much greater yield of colouring matter than heretofore. Improvements in this direction have already been effected in consequence of the application of machinery to the manufacture and further improvements will doubtless take place. There is one improvement, or rather modification, of the process of manufacture for a special purpose which I would suggest. I have shown that indigo-red, or indirubin—a red crystallised colouring matter which always accompanies indigo blue in commercial indigo, and is, in fact, isomeric with it—may be produced in much larger quantities than usual by modifying the process whereby the indican of the plant is decomposed. Would it not be possible, it may be asked, by suitable contrivances to produce in India a real red indigo—a product in which the indigo-blue shall be largely, if not entirely, replaced by indigo-red—a product

which I am told would be of value? It appears, according to information kindly supplied to me by Mr. C. Rawson, of Bradford, that this end has, to a certain extent, been attained in India by adopting processes in which a base, such as lime or ammonia, is made to intervene at a certain stage of the manufacture. Mr. Coventry's patent process depends on the use of lime, and yields a product containing about 12 per cent. of indirubin, ordinary indigo having little more than 1 per cent., and of which a firm of dyers in Yorkshire say: "For vat dyeing it is an ideal indigo, the shades obtained in dyeing being very fine and bloomy."

That it has been found impossible successfully to replace natural indigo by an artificial product may from a moral and esthetic point of view be regarded as not altogether a misfortune. To replace a manufacture depending on an interesting organic process carried on under healthy conditions mostly in the open air, a manufacture which brings wealth into poor districts, and introduces system and order and civilisation among uncultured peoples, by one carried on perchance in some dingy sepulchral cave in a chemical works by some fixed and unalterable process, might from a higher point of view, be a doubtful advantage.

I may here interpolate a few remarks on a similar subject, the formation and employment of artificial alizarin. From a sentimental point of view it may perhaps be regretted that the process of dyeing with artificial alizarin has so entirely taken the place of dyeing with the natural product madder-root. The latter process is in many respects most interesting. Beginning with the glucoside of alizarin naturally contained in the root and extracted with water, we have first the decomposition of this glucoside under the influence of an enzyme peculiar to the plant and extracted at the same time, with formation of alizarin and other colouring matters; then the fixation of the latter on the mordants; lastly the removal of the colouring matters other than alizarin, together with other impurities, by various reagents, such as soap, acids, chloride of tin, &c., leaving a ternary compound of alizarin, fatty acid, and mordant as the final product. I can conceive no process more elegant and complete in this department of technical chemistry. Artificial alizarin, on the other hand, is supplied ready made to the dyer and printer, and though its formation is owing to a most interesting process, the elaboration of which is due to the genius of several distinguished chemists, there is nothing especially interesting in its application.

I may mention, what is sufficiently evident but is sometimes forgotten, that the various processes by which alizarin, indigo, and other organic substances are formed artificially throw no light whatever on what goes on in the plants yielding them. It is absurd to suppose that the plant should employ such substances as anthracene and phenylglyceoll as bases on which to build up its alizarin and its indigo. The natural laboratory of the plant must differ very widely from the chemical one, and we have as yet not the least conception of what goes on in it. At one end we have  $\text{CO}_2\text{H}_2\text{O}$  and  $\text{NH}_3$ , at the other end perhaps indigo; the intermediate stages are involved in mystery.

I have now come to a point at which it may probably be expected that I should say something about modern, i.e., more especially artificial colouring matters and their application in the arts of dyeing and printing. This is a very extensive subject, and I must, for reasons already given, confine myself to a few general remarks, and these will refer chiefly to a comparison of modern methods with those employed when I was conversant with the arts I have named. I had recently an opportunity of visiting the works of an eminent calico-printing firm near Manchester, and, though my visit was too short to enable me to go much into details, I arrived at the conclusion that this branch of manufacture had, during the last 40 years, been entirely revolutionised. I say nothing as regards mechanical contrivances, but on the chemical side everything is new. There are new mordants used, such as salts of chromium, tannin, and tartar emetic—all unknown in my day. To these may be added salts of titanium, the use of which has recently been recommended; then a host of artificial colouring matters, basic colouring matters, direct colouring matters, and so on, which are of recent introduction and require in their application new and refined

\* "On Indigo Manufacture," by J. Bridges-Lee, M.A. Calcutta: Thacker, Spink, and Co. 1892.

processes. The number and variety of artificial colouring matters introduced have been so great that at one time it was thought the natural compounds would be entirely superseded and replaced by artificial ones. This, however, has not been entirely the case. I was pleased on my visit to the printworks alluded to, to meet with an old friend—the indigo vat, essentially the same as I knew it, though somewhat altered as to details; also the Schlieper and Baum process of printing indigo, which was invented in my day, though not much used then. Alizarin, too, still maintains its ground, in the form, however, of the artificial product, associated occasionally with another artificial product, flavo-purpurin, a substance which was first prepared in my laboratory, and is, therefore, specially interesting to me. Alizarin colours, more especially Turkey red, will have, however, to undergo severe competition from a new and brilliant red dye, paranitraniline red, of which much has been said and written of late. In spite of opposition, however, alizarin dyes will probably, like indigo, continue to hold their ground for some time to come. That there still remains something to be done in the chemistry of natural colouring matters is proved by the memoirs which appear not unfrequently in English and foreign scientific journals. Not long since there was published an able paper on Curcumin, the colouring matter of Turmeric, by L. G. Radcliffe, of the Manchester Technical School. Quite recently the same investigator has taken up the subject of safflower. He has obtained its colouring matter in a crystalline state, and he informs me that he has little doubt of its being a glucoside, a form under which most natural colouring matters appear in the organisms containing them.

The most useful of all the artificial colouring matters, both as regards variety of tint and other properties, are the azo colouring matters. It would appear that the great importance assumed by these colouring matters in various directions is entirely justified by their manifold properties, and the possibilities of this wonderful group seem to be still unexhausted. Among the colours belonging to this group are several blacks, such as Diazo-black, Diamine-black, Columbia-black, and others, which, together with Aniline black, form perfect substitutes for the logwood black of former days, so that the discovery of a method of producing hæmatoxylin artificially is not such a desideratum as it was once thought to be.

I will not here enter on the vexed question of the comparative stability towards light and other agents of natural and artificial colouring matters and the dyes derived from them, about which opinions vary, but I may be permitted to allude *en passant* to the theory of dyeing, as to which much has been done and written of late, chiefly in order that I may enter a renewed protest against the chemical and in favour of the physical theory of dyeing, so far at least as regards cotton. Dr. Knecht, by ingenious experiments, has proved that the dyeing of wool is to a large extent a chemical process, *i.e.*, that wool contains organic substances which act as mordants and unite with colouring matters to form lakes. Cotton fibre, on the other hand, does not contain anything of a lake-producing nature, except it be a minute quantity of an albuminous substance which I found in my experiments on the constituents of cotton. Dr. Knecht, however, who has had much experience in this kind of investigation, is still of opinion that a substance or substances may be obtained from cotton which have the property of forming lakes with colouring matters. Prof. Mayer, of Naples, has lately sent me a copy of his memoir on the coloration of the cell nuclei of plants by various reagents, wherein he advocates strongly the chemical theory of coloration or dyeing in the cases coming under his observation. I am, however, not convinced by his arguments. A cell nucleus may be, and I suppose is, a nitrogenous body, and may therefore behave very differently to the cell wall, which consists of cellulose, towards colouring matters. I am at a loss to understand how, on the chemical theory, the union of such a body as carthamin, which is nearly insoluble in water and absolutely neutral with cotton fibre, which is also neutral and insoluble, to form a brilliant carmine dye can be explained—it seems to me to be a case of surface attraction. Again, in the case of the indigo vat, where we have a very weak acid united

to a strong base, can we suppose that the cotton fabric dipped into it seizes hold of the reduced indigo by chemical attraction, setting free the lime, soda, or other base with which it was combined? It seems to me that surface attraction, or whatever it may be called, is the only agent that can account for what takes place, and that the process is not chemical, but physical or mechanical. What I have said applies to cotton only, not to wool or silk. The question, however, is one mainly of academic interest. As regards practical dyeing, it can be a matter of little importance which theory is adopted.

#### *Adulteration of Food and Impurities in Water and Air.*

It is pleasant to be able to report that as regards adulteration of articles of food, a great improvement has taken place within the last few years in this district. In his report to the Cheshire County Council, Mr. Carter Bell, the able analyst for the county, says: "As I have now completed my 20th year as your analyst for the county of Chester, it will be interesting to look back upon these two decades and notice the vast improvement which has taken place in the supply of food to the public. Before the passing of the Food Adulteration Acts nearly every article of food was more or less adulterated. The difficulty then was to find purity, the difficulty now is to find impurity. In former times flour was found adulterated with chalk, bone earth, powdered flints, and plaster of Paris. Bread was adulterated with alum, sulphate of copper and sulphate of zinc, the two latter being very poisonous salts." This is a very satisfactory result so far as the various articles of food are concerned. As regards water supply the city of Manchester, with its neighbouring town of Salford, enjoy most favourable conditions, the supply being abundant, pure, and very soft. There is, therefore, no occasion for a periodic examination of its quality, as there is in the case of London water, the sources of which are always more or less suspect. The case is, however, very different as regards our effluents, the sewage and waste water of all kinds from the town or, rather both towns, and the drainage area generally. Here we seem to be surrounded by difficulties almost insurmountable. At the time when Manchester was much smaller, its population less, its trade prosperous, and sanitary conditions not much thought of, it seemed only natural that our one river should convey away the sewage and waste water of the town to the sea, what else could be done with it? But now circumstances have changed, more especially in consequence of the effluent water being impounded and stored up in the Manchester Ship Canal, where it ferments and decomposes, giving off fetid gases and objectionable odours. All attempts to remedy this state of things by purifying the water before allowing it to run into the canal seem to have been more or less in vain. All that seems certain is that a successful scheme, even if possible, is sure also to be a very costly one. Some of you will be conveyed to-morrow, I expect, down the Ship Canal, and you will be able to judge for yourselves what the present state of things is: no doubt it is highly disagreeable, at least in the upper part of the canal. Seeing what it is, there may perhaps be among you someone, who, by a sudden inspiration of genius, may see at once what is the proper remedy for this great annoyance and nuisance. The solution of that hitherto insoluble problem—the purification of our rivers and streams—may indeed be near at hand. In the meantime it may occur to some one of a sceptical turn to ask whether there is really evidence such as would satisfy a scientific inquirer, to prove that the waters of our polluted streams really have such a deleterious effect on the health of the riparian dwellers as is sometimes asserted. No doubt the mortality of this city, to take an example, is high, no doubt disease is rife, and its sanitary state somewhat unsatisfactory, but to what extent these defects are due to the state of our rivers and canals has to be shown. Objections to the present state of things are sometimes raised on sentimental and æsthetic grounds. Such objections, however, are not to be hastily brushed aside as being of no importance, for there is no doubt that what depresses the mind affects also the bodily health, but the question is whether we are justified, except on the highest and most urgent grounds, in saddling the towns and manufacturers of Lancashire—in face of a declin-

ing trade—with the enormous outlay, which, according to experts, would be necessary in order to effect the purification of our rivers to the satisfaction of the authorities.

The pollution of our rivers and streams may perhaps not affect many persons, but there can be no doubt that impurities in the atmosphere, especially in that of our large towns, are very sensibly and injuriously felt by the population generally. Impure water we may escape from—we have no occasion to use it, owing to the abundant supply of a wholesome article in most of our large towns; we need not dwell by polluted streams unless we choose; but impure air we cannot avoid; we are constantly enveloped by it; we draw it in with every breath, and are always exposed to its evil effects, and yet less seems to be done to neutralise its injurious influence than that of impure water. Distinguished investigators, such as the late Dr. Angus Smith and Dr. G. H. Bailey, of Owens College, have done so much in establishing the composition of pure and impure air that it would be useless to add a word to what they have said. Whether in this city any improvement has taken place as regards the less obvious impurities of the atmosphere I am not prepared to say, but as to the most obvious and obnoxious impurity—I mean that of coal smoke—I have no doubt that matters are much worse than they were years ago. In consequence of my dwelling occupying an elevated position, some 200 feet above the level of the River Irwell, in Manchester, I enjoy the advantage of surveying a considerable portion of the two towns of Manchester and Salford, and smoke and its emanation come in for a large amount of attention. That the amount of smoke has largely increased is evident from the fact that distant objects, such as the hills of Cheshire and Derbyshire, and even buildings on these hills, were formerly visible on clear days, and are now no longer seen on any occasion whatever. That this increased amount of smoke is due, as is sometimes asserted, to the number of small tenements erected of late years is, I think, not correct. Any one looking down from a height on the town, with its numerous chimnies, must be convinced that the chief part of the smoke comes from factories and works generally, whether new or old, not from small tenements. The state of things now prevailing is a disgrace to our manufacturers, a disgrace to our municipalities, a disgrace to the community generally. So much has been said as regards the best means of abating the nuisance that it would seem to be useless to add another word. I am assured by those familiar with the subject that the amount of black smoke emitted by our chimnies might be much diminished by judicious and systematic firing on the part of workmen; but whether this is so, and to what extent, I am unable to say. Of course, the contamination of our atmosphere by coal smoke is not at all times equally offensive. In dull, close—particularly foggy—weather, whether in summer or winter, it is peculiarly objectionable, the more so since at such times the carbon of the smoke is mixed with sulphurous acid from the pyrites of the coal. On the other hand, during or after rainy weather, the atmosphere in Manchester, and perhaps in other places, is comparatively pure and pleasant, the impurities being washed down by the rain. This would suggest the possibility of producing in our streets something like artificial showers of rain. A rose with small holes being attached to the end of a water-hose, water might be made to descend in fine rain, washing down the suspended carbon, the sulphurous acid, and other impurities, at the same time watering our streets quite as efficiently as it is done at present by the dribbles proceeding from our water-carts. I fear, however, that in spite of all that has been said about the unlimited supply of water in this town, there would not be a sufficient quantity to do this efficiently. The great distress caused to those suffering from pulmonary complaints by the dense fogs so often prevailing in this and other large towns has, I dare say, more than once suggested to inquirers the possibility of filtering the air before allowing it to enter our dwellings. The difficulties of such a device do not seem great in themselves; the real difficulty arises from the habits and prejudices of the people, who cannot understand the possibility of ventilation except it be through windows and doors. In his paper "On the Effects of Urban Fog upon Cultivated

Plants," Prof. Oliver mentions with favour a plan devised by Mr. Thorp, a horticulturist of Stepney, who causes the air entering his hothouses to pass through boxes containing trays with sticks of charcoal before impinging on the hot-water pipes, an out-draught of air being secured by means of "exhaust caps" placed on or near the ridge of the house. The plan, in Prof. Oliver's opinion, is an efficient one. That any such plan would succeed in private houses, as at present constructed, is very doubtful, but in institutions, such as hospitals, especially consumption hospitals, some such scheme might be tried, an essential condition of success being that all entrance of air except through the ventilating boxes be entirely prevented. How necessary this would be may be seen by the fact that when a fog prevails the atmosphere inside our houses is effected though the doors and windows are as effectually closed as they can be with our present arrangements, and, on the other hand, the fog inside a house disappears simultaneously with that outside, showing that there is a ready communication between the exterior and interior atmosphere, even when an absolute calm prevails, which is usually the case during fogs.

To impurity of the atmosphere are sometimes ascribed effects with which I believe it is not fairly chargeable. Of the disappearance of several species of birds in the neighbourhood of Manchester during the last 20—30 years, even in places where vegetation has not apparently suffered, there can be no doubt; but I am not sure whether it is due to the greater prevalence of smoke. Birds as a rule are not sensitive to impurities in the atmosphere. I was assured by a chemical manufacturer at Basle, that swallows come every year to his works and build their nests above the aniline stills, where human beings can hardly breathe. Insects, on the other hand, are very sensitive to atmospheric impurities, and cannot live in contaminated air; on this is founded the practice of gardeners in smoking their houses with tobacco, whereby the insect pests are destroyed without injury being done to the plants. Insects having disappeared in particular neighbourhoods in consequence, say, of increase of smoke, insectivorous birds would of course disappear too, for birds generally dislike to have to seek their food at a distance from home. I venture therefore to suggest, though I do it under fear of censure on the part of hygienists, that a moderate amount of smoke may actually be beneficial to vegetation, by covering the leaves and other parts of plants with a thin coating of carbonaceous or tarry matter, and thus rendering them unpalatable to insects. Of course the amount would have to be exceedingly small; for, if excessive, we should soon experience deleterious effects such as are seen in the scanty and blighted vegetation in the immediate neighbourhood of our large towns.

#### *Foreign Competition.*

A great deal has been said of late as regards the dangers to our manufactures from competition on the part of foreign producers. Indissolubly as we are wedded to the principles of free trade, it nevertheless becomes a matter of some importance to ascertain whether we are losing ground in our competition with foreign producers, not only outside but it may be even within our own country. From the speeches which are now and then made, one would infer that the danger is real and imminent, and that it behoves us with all possible speed to build and endow technical schools in which our workmen and others shall be trained so as to enable them to compete with the more highly educated class of similar standing in Germany and France. I am myself too little in touch with the manufacturing industries of the present day to say whether the danger is real and present, or whether it is merely apprehended and distant. If, however, it be permitted to draw conclusions from what one sees in travelling on the Continent, one might infer that competition with this country in many articles of trade is, at present at least, quite chimerical. Who that has seen what is offered to us in France or Germany in the shape of furniture, glass, or china, can help thinking that were free trade established between these countries and ours, many of the poor inferior articles of their commerce would be swept away to give place to

really good, substantial ones such as we could furnish or which they could themselves produce if exposed to the healthy influence of competition. In some departments of industry, especially the chemical and more especially that of colouring matters, foreign competition is, I suppose, a very serious matter, but whether the evil is one that can be remedied by mechanical and educational measures seems to me doubtful. The fact is that successful foreign competition may be due not only to superiority of education and training, but also to certain inscrutable, perhaps moral qualities, of which it is difficult to estimate the weight and bearing. As long as human beings exist there will always be differences of talent and disposition between individual and individual, and one nation and another. In technical, as in other matters, special talents show themselves. The English have always been noted for great mechanical undertakings, the Germans and French for the manufacture of chemicals, especially those of organic nature. In the middle ages Germans were the great alchemists, and the alchemy of former times is represented, one may say, by the organic chemistry of to-day, a branch of science which may almost be said to have had its origin in Germany. That specialities such as we see developed on a large scale in the case of different nations are also seen on a smaller scale in our own and other countries is well known to everyone. Boots and shoes are made in one place, hats in another. The woollen trade flourishes in Yorkshire, and different branches of it in different towns. In this country likewise different branches of the cotton trade have localised themselves in various places. Why we should deplore this state of things, as we might in adopting the principles of protection, I am at a loss to understand. Why should we not, in accordance with the principles of free trade, buy what we want where we can buy it best or cheapest? Why should we not buy silks in France and chemicals in Germany? Why should we determine to make all we require ourselves? Why should we imitate the example of the Grecian sage of whom we read in our school days, who considered it the height of philosophy to make all one wanted oneself and who appeared at the Olympic games in garments which, as well as the rings on his fingers, were of his own manufacture? These questions have often been asked and been answered by us in this country in one sense, and in other countries in a contrary sense. I believe myself that the principles of free trade are unassailable and will eventually everywhere prevail. Nevertheless, there is one article of commerce as to the introduction of which into this country the most pronounced free-trader might hesitate—I mean that of beetroot sugar, which is largely imported into this country and offers a very formidable competition to the cane-sugar of our Colonies. The exportation of this sugar from the countries where it is produced is bolstered up, as everyone knows, by heavy bounties, making the competition of cane sugar in countries such as ours, where free trade prevails, exceedingly difficult. Into the policy of this system of bounties this is not the place to enter. But from a chemical point of view, a few questions may well be put as to the properties of the various sugars entering into consumption in this country. The chemistry of sugars having attained a high degree of development, and the distinction between various kinds of sugar being, it is supposed, well understood, it may nevertheless be asked whether cane sugar and beetroot sugar are in reality perfectly identical, and whether, though their general behaviour is the same, there may not be some recondite physical properties in which they do not coincide. In the opinion of some experts beetroot sugar is much sweeter and more soluble in water than cane sugar. I have been told of one, who has worked much with sugars, and who states that there is a great difference between cane sugar and beetroot sugar as regards the rapidity with which they undergo change, the latter being inverted much more rapidly than the former. I have been informed also, that when the two sugars are presented to bees the latter prefer cane sugar to beet sugar. I do not attach much importance to these observations even if correct, since, as regards human food, differences such as those referred to would be of little importance. Differences of a serious nature do,

however, subsist between the two sugars as regards their respective mother-liquors or molasses—differences which might possibly be considered serious. The molasses of cane sugar may be and are largely consumed in the shape of treacle; those of beet sugar contain substances which render it entirely unfit for human food, and they are utilised accordingly in another way. Among these substances betaine is mentioned, and this there is good reason to suppose is a poison. Now it is quite possible that minute traces of this and other deleterious substances may be present in the finished product or sugar, and considering the enormous quantities of sugar consumed in this country the effect even of a minute poisonous impurity on the public health might be serious. However, poison or no poison, it might be maintained by purists—people who say that soda-water should contain soda, though the consumer may not want it, and arsenical soap sufficient arsenic to justify its name—that cane sugar and beet sugar should be respectively labelled as such. The whole subject is one that merits exhaustive inquiry. While on the subject of sugar, I may mention the fact, not generally known, that a distinguished chemist, Dr. Leon Marchlewski, a former collaborator of mine, has succeeded in preparing cane sugar artificially (see page 622). Following the lines laid down by Michael, who was the first to prepare an artificial glucoside, he brought together pure acetochlorhydrase and freshly prepared potassium levulose in presence of alcohol, and obtained a small quantity of a product which had the properties of cane sugar. This important discovery, though it is not likely to have any immediate practical consequences, opens out a vista stretching far away into the *terra incognita* of the constitution of organic compounds. For this discovery the Academy of Sciences of Cracow awarded a prize to its author; if every other academy in Europe had done the same it would not have been more than the discoverer merited, considering the importance of his work.

There are other subjects to which I might have referred on this occasion, but considering that this address is already long enough for my powers of speaking, and probably too long for your patience, which must by this time be thoroughly exhausted, I will bring it to a conclusion without extending it further, thanking you heartily for listening to what I feel is scarcely worthy of the occasion.

Prof. F. CLOWES (President-elect) moved a vote of thanks to Dr. Schunck for his address. Dr. Schunck, he said, might be old, but he was still in a large degree active. His reputation was world-wide, and he conferred dignity on the Society by assuming the Presidential chair. He remembered that, years ago, in Manchester, Dr. Schunck presided over Section B of the British Association, meeting in that theatre. Many foreign chemists were present, and one and all acknowledged his eminent position as a researcher. His address that day had been delightful. If there was one word that he would add to it, it was that, since the address was written, a bacterium had been found existing in strong spirits—in fact, in rum (see page 626). But that did not in any way affect the argument of Dr. Schunck.

Mr. G. BEILBY, in seconding the motion, said that Dr. Schunck had spoken of the high tone prevailing in that Society. He would say that nothing would so much contribute to the maintenance of that tone as a study (such as that they had just heard) of the biographies of the great chemists who had preceded them. They were very grateful to Dr. Schunck for the charming reminiscences he had given them of Dalton and others, and it was a matter of satisfaction that his address would be preserved in the Journal. What the President had said about foreign competition would do the greatest good.

The motion was adopted amid applause.

Dr. SCHUNCK, in responding, said he was grateful to the assembly for their great cordiality, and for the way in which they had listened to his long address. He only regretted that he had been unable to put into his paper something that might have been original, as other Presidents had done, but that could not be expected at his age. He thanked Prof. Clowes for his words, and would say with Mr. Beilby that they ought to read as much as possible of the history of the scientists.

## THE COUNCIL.

The Secretary announced that the election of the Council had resulted as follows:—

*President:*

Prof. F. Clowes, D.Sc.

*Vice-Presidents:*

David Howard.  
Prof. A. K. Huntington.  
Ivan Levinstein.  
Boverton Redwood.  
Sir H. E. Roscoe, F.R.S.  
A. Gordon Salamon.

Dr. W. Jay Schieffelin.  
Dr. Edward Schunck, F.R.S.  
G. N. Stoker.  
Dr. T. E. Thorpe, F.R.S.  
Wm. Thorp, B.Sc.  
Thomas Tyrer.

*Ordinary Members of Council:*

G. Bailby.  
R. Forbes Carpenter.  
R. Le Neve Foster.  
Sir David Gamble, Bart., C.B.  
Oscar Guttman.  
Douglas Herman.

Prof. J. J. Hummel.  
C. C. Hutchinson.  
J. S. McArthur.  
B. E. R. Newlands.  
John Pattinson.  
Walter F. Reid.

*Honorary Treasurer:*

E. Rider Cook.

*Hon. Foreign Secretary:*

Ludwig Mond, F.R.S.

## AUDITORS.

On the motion of Mr. A. E. Fletcher, seconded by Mr. F. Napier Sutton, Messrs. Miall, Wilkins, and Co. were appointed auditors at a fee of 10l. 10s.

## IMPERIAL INSTITUTE REPRESENTATIVES.

Prof. A. PEDLER proposed that Mr. E. Rider Cook be the Society's representative on the Imperial Institute. As one who had been connected with India for a quarter of a century, he said he knew the good which that institution might do if properly directed. The other day he went through the Research Department of the Institute, and noted that a line had been struck out which he thought might be of considerable advantage to India and the various colonies.

Mr. T. C. CLOUD, of South Australia, seconded the motion, which was passed.

## NEXT YEAR'S MEETING.

Sir JOHN TERNEY, speaking on behalf of the Mayor and Corporation of the city of Nottingham, invited the Society to meet in Nottingham next year. In view of the election of Prof. Clowes to the Presidency, their city would be an appropriate meeting-place, and the members would have every welcome.

Mr. F. J. R. CARULLA, in supporting the invitation, said this was the first time they had been asked to come to a place by a municipality.

On the motion of Mr. Ivan Levinstein, seconded by Mr. B. Redwood, the invitation was accepted.

## VOTE OF THANKS.

Mr. GEO. E. DAVIS proposed a vote of thanks to the Council of the Owens College for the loan of the Chemical Theatre as a meeting-place.

Dr. KOHN seconded the resolution, which was passed.

This concluded the proceedings.

## VISITS TO WORKS AND PLACES OF LOCAL INTEREST, &amp;c.

After the conclusion of the morning's business, by invitation of the Manchester Section, luncheon was served in the hall of the Owens College Union. Mr. Tyrer then proposed the health of the Chairman of the Manchester Section, Mr. George E. Davis, warmly referring to the signal services he had rendered the Society in its earliest days, as one of its original founders.

After lunch a large number of the visitors, with their ladies, were conveyed to the residence of the President, at Kersal.

## DR. SCHUNCK'S GARDEN PARTY.

On arrival, the party was cordially received by Dr. Schunck, and whilst some passed the time in the grounds, where refreshments were provided, and the noted band of Besses o' th' Barn was performing in a marquee, others went to inspect the President's splendid laboratory and scientific library, and to see the interesting exhibits there set out. Dr. Schunck's library contains about 1,000 volumes, including Liebig's *Annalen*, the *Berliner Berichte*, and the *Philosophical Transactions*, complete from the first volume of each work. The exhibits and specimens included the following, many of them, as it will be seen, serving to illustrate the President's address delivered in the morning.

*Chlorophyll Derivatives.*—Phylloxanthin, Phylloeyanin, Phyllotaonin, Methyl and Ethyl-phyllotaonin, Alkachlorophyll, and Phylloporphyrin.

*Indigo and its Decomposition Products.*—Indican, Indigotin, Diacetyl-indigotin, Diacetyl-indigo-white, artificial ludigotin, Diacetyl-dihydroxy-indigotin, O'Neill's acid, Indirubin, artificial Indirubin, Acetyl-indileucin. Isatin and substitution products, Hydrazones and Semicarbazones of isatin and substitution products, Amidophenimesatins, Indophenazines, Indoxyl and Di-oxindol, Anthranilic acid, Nitrosalicylic acids.

*Madder and Madder Constituents.*—Rubiad. Rubiadin and derivatives. *d*-Glucose from rubiadin, Ruberythric acid and acetyl derivatives. Alizarin, Purpurin, Purpuroxanthin and derivatives. Perchlorrubiadin.

*Natural Yellow Colouring Matters.*—Quercitrin, Quercetin and substitution products. *d*-Rhamnose, Soporin, Rutin, and derivatives. Xanthorhamnin and derivatives, &c.

*Natural Red Colouring Matters.*—Carminic acid (crystallised) and derivatives. Crocetin and crocin and derivatives. Carthamic acid, Brasilin and derivatives, &c.

*Glucosides.*—Phlorizin and derivatives. Salicin, Arbutin, Aesculin and derivatives.

*Carbohydrates and Allied Substances.*—*d*-Glucose, *d*-Fructose, *d*-gallactose and derivatives, Cane sugar, natural and artificial. The artificial sugar was synthesized for the first time by L. Marchlewski (see pages 594 and 622). Milk sugar, Maltose, Mannitol and derivatives. Inulin, Trahalose.

*Anthracene Derivatives.*—Anthracene and substitution products, Anthraquinone, &c., Alizarin, Purpuroxanthin, Quinizarin and derivatives, Anthraflavic acid, Isonthraflavic acid, Anthrarufin and derivatives, &c., &c.

*Naphthalene Derivatives.*—Naphthalene and substitution products. Naphthols, Naphthylamines and substitution products, &c., &c.

Mr. Chas. A. Schuuck demonstrated the spectra of Phylloporphyrin and Hæmatoporphyrin (see President's address, page 590), which, as will be seen from the figure on the preceding page, are practically the same; the only difference being, that in the case of hæmatoporphyrin the seven bands are slightly nearer the red end of the spectrum. Of these seven bands, the first in the red, as will be seen, is narrow, dark, and extremely well defined. It is the characteristic band. Then comes a very faint band near to the first, and just visible in the photograph but not in the figure, and then another faint band. After this appears a double one, in strong solutions looking like one uniform band, and finally two very dark bands. The wave lengths of the centre of the bands are approximately:—6250, 6120, 5950, 5750, 5650, 5250, 4900. The general absorption in the violet begins at about wave length 4370.

Instead of proceeding directly to the President's garden party (3 to 6 p.m.), a choice was offered of visits to several works and institutions of interest in the neighbourhood. These were as follows:—

#### THE MANCHESTER CREMATORIUM.

*Henry Simon, Esq., C.E., Chairman.*

The Crematorium is situated near Chorlton-cum-Hardy. It consists of a hall or chapel and a separate contiguous chamber containing the furnace. The hall is about 50 ft. long by 25 ft. wide, and of proportionate height. In the centre of the wall, opposite to the principal entrance, is placed the aperture leading to the furnace, which, in the separate space, occupies basement and ground floor. A vestry or record room, and a retiring room, lavatories, &c., are situated at the back of the hall. The style of the building is Romanesque, similar to that of some of the churches of Lombardy and Venice, and the material is terra-cotta. The furnace is considered to be ready for cremation as soon as the cremating chambers have attained a bright orange-coloured glow. The body can then be introduced, and after about an hour the process is complete. The intense heat is such that of the wood of the coffin (light pine wood) absolutely no trace remains in the ash of cremation. At present, when the large furnace has to be heated up specially for each single cremation, the quantity of coke used amounts to something like one ton. Each cremation immediately following, however, would only require an additional two or three hundredweight of coke. In Paris, for example, where 10 or 20 cremations take place daily in the Père la Chaise Cemetery, the cost of fuel is very small indeed.

It is worthy of mention that the coffin, from its resting place in the chapel, at a given signal, passes by invisible mechanical means through the small door of the draped antechamber, to the furnace.

The intense heat used in the furnace for the Manchester Crematorium is said to be an absolute guarantee against the possibility of nuisance of any kind. In the base of the chimney—which occupies the centre of the tower attached to the Crematorium, and has a height of 75 feet—there is a second coke fire provided, through which the gases proceeding from the principal furnace can be passed. It has so far been found totally unnecessary to use this fire.

The arguments given for the crematorium and cremation are based on statements by Lord Playfair and Sir Henry Thompson: the former to the effect that “in most of our churchyards the dead are harming the living by destroying the soil, fouling the air, contaminating water-springs, and spreading the seeds of disease”; the latter to the effect that even in the case of suburban cemeteries, “these latter rapidly become urban, and will one day be found in dangerous vicinity to our homes.”

#### THE MANCHESTER CORPORATION GASWORKS, GAYTHORN.

The Gaythorn Gasworks, thrown open to members, covers eight acres of ground. There are 65 beds of retorts, the number of mouthpieces being 776. The systems of charging are (1) by hand, (2) the Foulis-cum-Woodward system. The total carbonising power is 430 tons, and the producing power 4,300,000 cubic feet, the gas-holder capacity being 6,010,000 cubic feet. The ratio of storage to consumption is 113·5 per cent. The corresponding consumption of cannel is 18,000 tons, with 4,000 tons of coke,

and the yield of tar and ammoniacal liquor is 750,000 gallons. The largest daily consumption of gas in Manchester recently, was on January 11th, 1897; it was 23,824,000 cubic feet, the largest weekly consumption being for the week ending December 24th, 1896, with 136,000,000 cubic feet. Of the works furnishing this supply of gas, Gaythorn is only one of several, the others being the Bradford Road Works, the Rochdale Road Works, and the Droylsden and Poland Street Works.

The total area of supply is: Within the city, 12,788 acres; beyond the city, 12,382 acres; and beyond the Mersey, 4,640 acres. Total, 29,810 acres. Extreme limit of supply, 10 miles. Percentage of consumption: Within the city, 86·58 per cent; beyond the city, 12·66 per cent; beyond the Mersey, 0·76 per cent. Total number of lamps within and beyond the city, 16,000.

At the Bradford Road Gasworks a carburetted water-gas plant is being laid down on Humphrey and Glasgow's system, to make, when completed, 6,000,000 feet of gas per diem.

#### THE MANCHESTER CORPORATION ELECTRIC LIGHTING WORKS.

The generating station is in Dickenson Street, near Portland Street. The works were designed and their erection superintended by Dr. John Hopkinson, F.R.S. The generating plant had a capacity of 3,000 h.p., though the buildings were constructed of a size to admit of considerable additions. In July 1894, the resident engineer, Mr. C. H. Wordingham, took over the consulting work, and since this all extensions have been carried out to his designs. The capacity of the generating plant is now 6,200 h.p., and this will be increased to 10,600 h.p. when the extensions now in progress are completed. The system employed is entirely low-pressure, and is the multiple-wire direct current, with feeders. The greater portion is on the five-wire system, the pressure of supply to consumers being at 100 volts, whilst a portion is on the three-wire system, the pressure of supply to consumers then being at 200 volts. The following small table will indicate the rate of increase of demand for electric lighting, as well as present supply:—

Year ending March 31st.	Quantity sold.	Total Maximum Supply demanded.
	B.T. Units.	Watts.
1894 (8 months) ..	439,370	651,500
1895 .....	1,168,382	1,187,000
1896 .....	1,748,214	2,082,000
1897 .....	2,508,588	2,737,400

#### THE HYDRAULIC POWER SUPPLY, GLOUCESTER STREET.

The Hydraulic Pumping Station is adjacent to the Rochdale Canal, Oxford Street, and the mains are kept charged by means of six sets of powerful engines, each capable of delivering 230 gallons of power-water per minute. Steam is generated in five large boilers, fitted with mechanical stokers, economisers, coal conveyors, &c. The reservoir of power consists of two capacious accumulators, loaded to a maximum pressure of 1,120 lb. per sq. in., thus producing the same effect as if large supply tanks were placed at an elevation of over 2,500 ft. above the ground level. The power-water will be maintained in the mains at a pressure of 1,000 lb. per sq. in., and is available day and night within the area of supply all the year round, Sundays and holidays included.

The system of supply has been in operation for nearly two years, and upwards of 13½ miles of mains are now laid within the principal streets in the city, from which supplies are given to over 240 premises, and representing about 870 machines for various purposes.

#### THE MANCHESTER CORPORATION COLD-AIR STORES, ELM STREET.

In 1893, the Markets Committee of the Manchester Corporation resolved to establish—as an adjunct to their extensive markets—cold-air stores for the preservation of perishable goods, the main object being to minimise the hitherto great waste of the meat supplies of the city and

neighbourhood, and to furnish these supplies to the people in a sound and wholesome condition. The buildings were commenced in June 1893, and completed and equipped with machinery, &c., on January 31st, 1895. These stores consist of a square block of brick buildings, about 130 ft. long by 120 ft. wide, and 75 ft. high from the basement floor, with provision for extension upwards, should trade requirements demand it. They contain a basement, ground floor, and three upper floors. The building is constructed to accommodate 120,000 sheep, distributed as follows:—In the basement, about 20,000 sheep or other goods. In the six chill rooms on the ground floor, about 25,000 sheep, or 1,260 sides of beef or other goods. On the first, second, and third floors, about 25,000 sheep on each floor. With regard to the heights of the rooms, these are as follows:—Basement, 10 ft.; ground floor, to accommodate sides of beef, 13 ft.; the first, second, and third floors, 9 ft. each. The roadways through the building are to have a clear headroom of 17 feet, and a clear width of 19–20 ft.

The plant consists of:—Two triple-expansion vertical marine engines, each driving direct two 50-ton Linde compressors. Each engine and two compressors are capable of refrigerating the whole of the chambers in the entire building to any reasonable temperature required, as well as chilling 1,200 sides of beef in 24 hours. Three Babcock and Wilcox boilers supply the steam necessary for working the steam engines, any two of which boilers can work both the refrigerating machines simultaneously, as well as two powerful electrical plants driven by special compound condensing steam engines, which are also interchangeable—one for the purpose of driving and circulating the air through the chambers, and the other for lighting the premises.

THE MANCHESTER AND SALFORD TECHNICAL SCHOOLS, PRINCESS STREET, MANCHESTER, AND PEEL PARK, SALFORD, were also thrown open to the inspection of the members.

#### RECEPTION BY THE LORD MAYOR OF MANCHESTER AND THE LADY MAYORESS, IN THE MANCHESTER CITY HALL.

In the evening, the members of the Society, with their ladies, were cordially received and entertained in the City Hall by the Lord Mayor of Manchester, Mr. Alderman J. F. Roberts, and the Lady Mayoress, Miss Roberts. An admirable programme of music was provided. Mr. Herbert Walker, Mr. Roland Hoyle, Mr. Bertram Smith, Miss Nellie Leeson, and Miss Adela Carlton took part in the singing, while some fine instrumental music was played by the band of Messrs. Forsyth Bros. in the Great Hall. Nearly 700 ladies and gentlemen were present.

#### SECOND DAY.—THURSDAY, JULY 15.

##### SIR THOS. WARDLE'S LEEK EXCURSION AND THE MANCHESTER SHIP CANAL VISIT.

Thursday may be said to have been spent in two directions—one party of about 50 leaving the landing-stage of the Ship Canal in Manchester, opposite the Cathedral, at 9.30 a.m. for an excursion as far as Latchford; another party of over 80 accepting Sir Thos. Wardle's invitation to Leek, Staffordshire. This party was received by Sir Thos. Wardle and Miss Wardle at Leek Station, and conveyed in waggons to the Dyeworks, managed by Mr. Gilbert Wardle, where the members were divided into groups and separately conducted through the different departments of the works by Sir Thos. Wardle and his son.

At one o'clock the party was driven back to Leek, and there entertained at lunch by Sir Thos. Wardle, whose efforts to entertain and please his visitors were unceasing, and, it may be added, completely successful.

After lunch, Dr. Bowman proposed, and Dr. Clowes seconded, the health of Sir Thos. Wardle and family, and Mr. Tyrer proposed a vote of thanks to Sir Thomas for his generous entertainment of the visitors, and for so kindly throwing open his works for their benefit.

##### SIR THOS. WARDLE'S SILK DYEWORKS.

The visitors were shown here the various kinds of machinery for washing the silk; also various processes of

dyeing black, more especially those for the dyeing of the warp and weft for the sailors' handkerchiefs ordered each year by the Admiralty, in which the weighting is stipulated to be very low, and the permanence of the dyes is secured. The dyeing of silk in various colours excited considerable interest, as also the bleaching of Tus-sah silk, in which the natural yellow colour is reduced to a clear and pure white, to be followed afterwards by dyeing to a variety of the most delicate and pale shades of colour. The dyeing of the Raven black, for which the firm has maintained for long a just celebrity, was next shown to the visitors. This is an unweighted colour, resembling that of the bluish-black of the raven's wing, in the production of which an extremely dilute solution of tannate of iron, produced by a mixture of iron and the bark of the alder tree, plays an important part. The dyeing of all kinds of black colours and shades of white was also demonstrated. Apparatus was seen and explained for wringing, stringing, dyeing, and lustring of silk.

##### EXCURSION FROM LEEK OVER AVE EDGE.

At 3 p.m. the party proceeded, by carriages and brakes provided by Sir Thos. Wardle, over Ave Edge—2,000 feet high, and surrounded by lovely hill and dale scenery—to Buxton, the visitors thence journeying to Manchester at 5.30 p.m., so as to be in time for

##### THE ANNUAL DINNER.

The Annual Dinner was held on Thursday, July 15th, at 8 p.m., in the Grand Hotel. The President, Dr. Schunck, occupied the chair, and among those present were Prof. Clowes (President-elect), Sir Henry Roscoe, Mr. Tyrer, Mr. G. E. Davis (Chairman of the Manchester Section), Mr. Ivan Levinstein, Dr. Bowman, Mr. G. Beilby, Dr. Macadam, Dr. Böttlinger (Elberfeld), Prof. Alex. Pedler (Calcutta), and Mr. J. Carter Beil.

The President proposed the toast of the Queen, which was duly honoured.

Prof. F. Clowes, D.Sc., proposed "The Society of Chemical Industry." He thanked the members for the honour they had done him at the recent annual meeting in electing him to succeed Dr. Schunck as President. Dr. Schunck had regretted that the burden of years had prevented him from doing as much as he would have liked for the Society. Well, he was young enough to be Dr. Schunck's son; and if comparative youth was an advantage, he hoped to be able to justify to some extent the confidence the Society had placed in him. He felt that in selecting him as their President for the new year, they were really doing honour to the Nottingham Section, which in some measure he represented. The Nottingham Section was one of the youngest members of their large and growing family. Started in connection with the University College, it had become a centre of great interest, and included members from Birmingham, Derby, Leicester, Burton, and, in fact, all the midland towns within easy access by train. The widespread interest in the work of the Section had led the committee to arrange for occasional meetings in the various towns in which they had a body of members. He believed no other Section of the Society followed this practice, but he thought it might with advantage be imitated in other Sections. It had led, in the case of Nottingham, to a very wide interest in the work of the Section—wider, he believed, than in any other Section. He mentioned these things to show that, though a young section and a small section, they were full of energy, and had done something for the general good of the Society. The membership, as the report of Council had told them, was now over 3,000. This was a large constituency, and he was glad to say it was not confined to the United Kingdom. The success which had attended the Society must be very gratifying to the men of Manchester who founded it, and especially to Sir Henry Roscoe, its first president; and it was a proof that the Society had met a want felt by chemists, not only in this country, but in other countries as well. He trusted that the classification, sometimes attempted, into professional, professorial, and industrial chemists would not be pushed too far. All chemists were now very generally trained up to a certain point in the same way, and their qualifications and

pursuits were to a great extent identical. He coupled the toast with the name of the retiring President.

Dr. SCHUCK, in responding, said the Society was sometimes said to be on the verge of bankruptcy, but somehow or other they not only kept out of difficulty but prospered. No society ever did die of bankruptcy, and he had no fear for the Society of Chemical Industry. During his presidency he had been struck with the want of cohesion between the different Sections of the Society. In one way it was a peculiar society, consisting, as it did, of sections, each of which met separately. Between the various Sections there was far too little connection. For example, there were the Liverpool and Manchester Sections; they were not far from each other, and yet, for any connection there was between them, one of them might be meeting at Timbuctoo. Of course, the Journal of the Society helped to keep the Sections together, and let them know what was going on; but this was not enough—where it could be managed Sections should occasionally have joint meetings. They in Manchester, for example, should go to Liverpool now and then, and have an evening there, and the Liverpool Section should, in the same way, occasionally come to Manchester. Such joint meetings would add to the unity, concord, and good fellowship of the members. A good deal had been done in this direction by his predecessor in the chair, who was in the habit of making visits to the Sections. This, of course, was very good so far as it went, but could not have all the pleasant consequences one would anticipate from a visit of one section in a body to another section. Another thing which struck him as a defect in the constitution of the Society was the lack of opportunity for the discussion by the Society of important questions which cropped up from time to time. There was only one general meeting during the year, and as an immense quantity of business had to be got through in a short time, there was no opportunity for taking into consideration questions of general interest. An example of this had occurred on the previous day, when a highly esteemed member of the Society brought forward a question which had to be answered very shortly, though it might well have been discussed for an hour or two. There ought, he thought, to be a regular meeting of the Society for the discussion of such questions—questions of vital interest, and not merely business questions. These were, perhaps, the only points of importance which had struck him during his presidency. Unfortunately he had not been able, like his predecessor, to go about among the Sections, but he had done what an old man could to advance the general interests of the Society.

Mr. T. TYLER proposed the toast of "Science and Industry." He said that no technological work could be successfully carried on without the application of scientific principles; that was why in some cases chemical industries did not succeed so rapidly as they might. He believed we were rapidly getting out of the region of rule of thumb. Foremen were beginning to believe that masters knew as much as they did themselves, and it would be a happy day in the chemical industry when the workmen came to be of the same opinion. The want of success in chemical industry was often due to the obstinacy of the British workman. There was certainly great need for better discipline among the men—better discipline and a more ready and prompt obedience. A good deal was said from time to time about foreign competition, and particularly German competition. His own view was that with equal conditions we had little reason to fear; but it was worth bearing in mind that in some respects the conditions were not at present equal—for instance, in the education and discipline of our workmen. He was glad to have the privilege of connecting Sir Henry Roscoe's name with the toast, as representing the first branch of it. No worthier representative of chemistry could be found than the first President of the Society, to whom they were under a great debt of gratitude for his early work in connection with the Society. Sir Henry saw that if it was to become an international society it must have its headquarters in London. Still they could never forget that it was born in the energetic atmosphere of Manchester. Mr. Tyler also spoke of the work done by Sir Henry Roscoe at Owens College, and the large number of good men he had turned out from

his classes. One secret of his success was that, like Bunsen and Hoffmann, Sir Henry worked side by side with his students in the laboratories, and was not content with a mere perfunctory supervision.

Sir HENRY ROSCOE, in responding, said this was the third time the Society had visited this great hive of industry, and it was a fact on which both the Society and Manchester were to be congratulated. It was true, as one of the speakers had said, that he had taken some share in the work of starting the Society. He remembered Mr. Muspratt, Mr. Carey, and one or two other gentlemen interested in the chemical industry, coming to Owens College to consult with him as to how they could best bring together the men of science and the men of practice. The first idea was to make it a local institution, but he suggested that it would be better to take in the whole country. The result had been extremely encouraging. Indeed he knew of no society of an industrial and scientific character which in this generation had been so successful. Perhaps no other chemical society had so many members. The existence of the Society was of itself a proof of the need for a close connection between science and industry. But he need not preach to the converted. They all knew as well as he that industry without science was nothing but rule of thumb; and rule of thumb, he was glad to say, was dead. If we were to maintain the supremacy of England in chemical and other industries, we must unite industry with science in its latest and best forms. A good deal had been said about German industries, and particularly chemical industries. Well, they all admired the work the Germans were doing in that direction, but it was not to be supposed that we were doing nothing of the same kind. It was, indeed, not too much to say that the greatest discoveries in science had been made by Englishmen; but in saying that he had no wish to belittle the work done on the Continent. There were many things in which we could learn from our German friends; they had certainly produced some wonderful results in regard to colour.

Dr. F. H. BOWMAN also responded to the toast, speaking on behalf of industry. He said that science was, after all, only the rational interpretation of the nature of things; and if they worked contrary to the nature of things they could not hope for the best results. It was a good omen for the future of the country that we were now thoroughly aware of the fact that our success would depend on the scientific training of the rising generation. He had been asked specially to reply for cotton. At one time he employed in that industry nearly a thousand hands, and he had found many directions in which the scientific spirit could be applied. He had the same experience in the woollen industry; and, indeed, it would not be easy to find an industry in which science had nothing to say. The Society, he was glad to think, was doing much to stimulate the scientific spirit in this great country.

Mr. G. BEILBY proposed the health of "The Guests," coupling the toast with the name of Dr. Böttger, of Elberfeld, the head of one of the largest chemical works in Germany.

Dr. H. T. BÖTTGER said that though he was a member of the Society, he might, being a foreigner, fairly enough consider himself a guest in Manchester. Meetings of this kind seemed to him to be of great value, if for no other reason than that they enabled them for a time to get away from the small jealousies of commerce. England had good reason to be proud of the position it occupied in the chemical industry. So far as inorganic chemistry was concerned England had the first place; in Germany they had gone in more for the development of organic chemistry. He hoped the spirit of commercial and scientific fraternity would always be the governing spirit of the Society.

Dr. MACADAM proposed "The Local Section." He said the Manchester Section was an extremely strong one, and had done much good work. To say that it was managed by Manchester men was another way of saying that the management could not be improved.

Mr. H. GRIMSHAW and Mr. CARTER BELL responded, and this brought the speaking to a close.

## THIRD DAY.—FRIDAY, JULY 16.

## VISIT AND EXCURSION TO BEESTON AND PECKFORTON CASTLES.

Still favoured, as all through these meetings, with exceptionally magnificent weather, a very large party of members and their ladies assembled at London Road Station at 10 a.m., and took train to Beeston, *via* Crewe. After ascending the hill crowned by the ruins of the ancient castle, the party partook of lunch in a marquee. Later on a small party visited Peckforton Castle. The party then drove in wagonettes to the Iron Bridge, where the ladies and those not electing to return to the Smoking Concert, remained for tea, the rest of the party driving on to Chester direct, and then taking train for Manchester. After tea, whilst one portion walked on to visit Eaton Hall, the seat of the Duke of Westminster, the remainder were entertained, *al fresco*, with humorous recitations, readings, and songs, by Messrs. Watson Smith, A. H. Allen, Dr. Bowman, and Mr. Turner. They then sailed down the river to Chester, returning by train to Manchester at about 10 p.m.

## THE SMOKING CONCERT.

Those who left Chester for Manchester at an earlier hour, joined in a Smoking Concert at the Grand Hotel, at 8.30 p.m. This function was presided over by Dr. J. Lewkowitsch, whose name will be remembered in connection with the successful smoking concert of 1895, in Leeds. Here, as in Leeds, an attractive programme of recitations, songs, humorous speeches, and narratives was carried out, and much amusement was caused by Dr. Lewkowitsch's humorous and suggestive proposal for a "new process, based on strictly scientific principles, for treating and purifying alkali and air." In this the services of a variety of waste products, such as spent soap lyes, canal, street, and kitchen greases, and various works' residues, vapours, &c. were to be enlisted, most, if not all, the recovered or resuscitated articles of value being shown upon the table!

## FOURTH DAY.—SATURDAY, JULY 24.

## VISIT TO THE WORKS OF IVAN LEVINSTEIN AND CO., LIMITED.

By special invitation a party of about 40 assembled at the Grand Hotel at 10 a.m., and proceeded in wagonettes to Crumpsall, where the extensive works of Levinstein, Ltd., are situated. Here they alighted and were shown round the various departments of the factory by Mr. Levinstein himself, who explained in outline the leading processes involved in preparing from crude naphthalene, the naphthols,  $\alpha$ -naphthylamine, and naphthionic acid, as well as some of their azo derivatives, which form naphthalene dyestuffs.

He also showed the company that so large is the firm's business in the manufacture and export of naphthol and naphthylamine, &c., that it was deemed necessary to engage in the manufacture and rectification, on the spot, of sulphuric acid, and the sulphuric acid chambers, pyrites kilns, and rectifying plant were exhibited and explained.

Mr. Ivan Levinstein commenced coal-tar colour manufacturing at Blackley, about 30 years ago, on a very small scale, the range being then confined to Magentas, Violets, Bismarck Brown, Chrysoidine, Blackley Blue, &c. These works were then transferred to Crumpsall about 12 years ago. About 400 people are employed in the present works, and the chemical staff, inclusive of that in the dyeing laboratories, comprises 18 head chemists, 12 assistant chemists, and about 15 youths, apprentices, and boys. There are special laboratories, solely designed for scientific research, in which about eight chemists are engaged.

As the party proceeded to the inspection of the vitriol plant, attention was drawn to a large number of casks containing naphthalene derivatives intended for Germany, all of which were conspicuously marked "Made in England"—a fact which seemed to afford considerable amusement to the visitors.

The vitriol plant, which had been designed by Mr. Geo. E. Davis, was producing 100 tons of acid per week, all of

which was used on the works. The rectifying plant consists of lipped glass beakers arranged in descending series, and brings the chamber acid up to 96 per cent., 97 per cent., and 98 per cent. acid. Glass retorts are used. The remarkable freedom of the retort house from the irritating fumes of sulphuric acid was the subject of remark by several of the visitors, and Mr. Levinstein added that remarks to the same effect were made either by the district or the chief alkali inspector whenever he visited the works. Mr. Levinstein drew attention to a notable feature of the works, namely, that there was no transport or handling of vitriol in carboys anywhere, but the acid was collected in a central cistern near the rectifying house and was forced by means of air pressure and acid eggs into secondary reservoirs, situated in the various departments, where it was simply necessary to draw off into measuring boxes the required amount of acid for the individual operations. Wrought-iron pipes were used, and were preferable, on account of their lightness, for the overhead transport of the acid. The present installation had been in use six years, and was still good. After the nitric acid plant, which was of the usual type, though characterised by several minor conveniences in regard to arrangement, had been visited, the inspection of the plant for the manufacture of the organic products was proceeded to.

The naphthalene stills were first visited. These are charged with naphthalene from a separate store, and are wholly separated from the condensing and rectifying plant, thus minimising the risk of fire which always attends the distillation of this product. Between 400,000 and 500,000 lb. are rectified per month, the product obtained from the first distillation being subsequently twice distilled, finally refined, and crushed, when it is ready for use in the various departments.

The plant for the manufacture of nitronaphthalene was next visited; the importance of preventing the formation of the dinitro product was explained by Mr. Levinstein, who stated that 180,000 to 200,000 lb. of the nitro-compound were produced per month. Proceeding, the party passed through the reduction house, where the nitro-compound is reduced with hydrogen (obtained from iron filings and hydrochloric acid) to form naphthylamine. It was shown that great efforts are made to remove all vapours of the ill-smelling  $\alpha$ -naphthylamine from the atmosphere by means of a vacuum apparatus, which draws off the air of the room and forces it to a fireplace or furnace.

In the next department visited, the process has to be carried on in retorts under a pressure of a ton to the square inch, and the elaborate precautions and tests made to ensure the safety of those working in this department were explained by Mr. Levinstein. Visiting the naphthol distillery, Mr. Levinstein dwelt upon the difficulties of dealing with this product, and he showed the ingenious methods that had been exercised in devising this plant. It is significant of how greatly chemical engineering affects the progress of chemical manufactures; for, despite the difficulties of preparation, the consumers were demanding greater purity every year, although the product—which is now produced in what is practically a state of chemical purity—sells at fewer pence per pound than it fetched shillings some years ago.

On the way to the colour-making plant the central air-compressing station was passed, from whence, apart from the numerous small compressors employed on the different plants, a supply of compressed air is furnished to all parts of the works by a splendid compressor built by Messrs. Klein, Schanzlin, and Becker, of Frankenthal. At the colour-drying stores also a new vacuum drier was shown, which, besides having the advantage of occupying 15 times less space than the ordinary stove, enables the colours to be dried at as low a temperature as 30° C.

The visitors were then shown the actual manufacture of naphthol scarlet—a colouring matter which has now almost entirely superseded cochineal.

Before leaving the works, specimens of cotton and woollen materials dyed with the Company's patented colours were inspected.

As already indicated, Messrs. Levinstein's firm is chiefly concerned in the manufacture of naphthalene derivatives, and in this special line, it is said to be the largest in Europe, two-thirds of the total production being exported to foreign parts. The different departments, each of which is managed by a staff of chemists are:—

#### Intermediate Products.

	Lb. per Month.
Naphthalene, with a production of about .....	400,000
Naphthol " " " .....	100,000
Naphthylamine " " " .....	180,000
Sodium naphthionate " " " .....	130,000
Isomeric naphthol and naphthylamine sulphonic acids, with a production of about .....	80,000
	Tons per Month.
Sulphuric acid, with a production of about ..	400
Nitric acid " " " ..	70
Benidine derivatives " " " ..	10

} For the  
firm's consumption.

#### Dyestuffs.

The special dyestuffs produced, are in the main derived from naphthalene, such as diazo colours, Scarlets, Fast Red, Yellows, Oranges, Clarets, Browns, &c., and Tetrazo colours, also direct dyeing colours, such as Congo Red, Benzopurpurin, Benzo Blue, Chrysamine, and other Salicylic acid dyestuffs.

Messrs. Levinstein's own patented dyestuffs are:—

Coomassie Black; Coomassie Navy Blue, for wool; Crumpsall Yellows and Oranges, for dyers and printers; Union Fast Claret; Dianol Red; Dianol Brown; Direct Blacks, for cotton and Union cloths; Crumpsall Direct Fast Browns and Reds.

After the inspection of the works was concluded, the visitors were driven back to the Grand Hotel, where Mr. Levinstein entertained them at lunch.

In an address, Mr. Levinstein said that he had thrown open the works of Levinstein, Limited, to members of the Society of Chemical Industry for the purpose of demonstrating to them—especially to his friends from the South—that the coal-tar industry was not only in existence, but that it was expanding in this country in spite of all that had been said to the contrary. He acknowledged that we were behind Germany in the quantity and variety of products manufactured from coal tar, but we were gaining ground, and with an amended patent law which would not, as hitherto, give all advantages to our foreign rivals at our expense, our progress would be still more noticeable. He referred to the International Congress on Technical Education, and thought that some of the professors had been rather hard on the manufacturers in blaming them for our backward position in regard to the chemical industry. It was stated at the Congress that this country was suffering from the fact that manufacturers did not appreciate the importance of highly trained men, and if they would only recognise the value of such work, we could turn out men as well as any other country in the world. Mr. Levinstein was, however, of opinion that in science the maxim that "the demand regulates the supply" does not hold good—the very opposite was the truth. Long before Germany possessed a chemical industry of any importance great schools were established in different parts of the country, directed by masters such as Woehler, Liebig, Kekulé, Hofmann, Baeyer, Victor Meyer, Fischer, and others, and to them and their disciples belonged the credit that German manufacturers were in a very much better position by having at their command a large number of highly trained men to take advantage of the discovery and the development of the coal-tar industry, first founded by an Englishman. It was undoubtedly the fact that the position which Germany held to-day in the chemical industries was due to their great masters in organic chemistry, and to their patent laws; whilst we, on the one hand, did not possess the highly trained staff of men, and, on the other hand, stifled our inventive genius and handicapped our industry by absurd laws. That our manufacturers did appreciate highly trained men was best proved by the fact that many hundred foreign chemists were employed in British works. Mr. Levinstein

also disputed the statement that we at the present time could turn out, in sufficient numbers, organic chemists of such training as were required by our manufacturers. Our whole educational machinery was yet insufficient for that purpose. The only laboratory that existed in this country which was solely devoted to the study of organic chemistry was at the Owens College. Its existence was only of recent date, but in spite of that, under the direction of his eminent friend Prof. Perkin, it had already made its mark by turning out men of a very superior class compared with those of former years, and those who had devoted sufficient time to their studies could readily find suitable employment; indeed, not long ago the director had more applications from manufacturers than he could satisfy. What they required was a number of organic chemical schools under eminent masters, similar to the Schorlemmer laboratory at Owens, a better preparatory education of the students when entering, and a more prolonged term of study. An organic chemist could not be sufficiently trained and prepared for works, either in Germany or here, under five years. Our manufacturers were, however, suffering from more serious causes than the insufficient training of our chemists. They were handicapped by the iniquities of our patent laws, to which he had repeatedly drawn attention, and unless these were amended all our efforts in regard to improved education would never bring back to us an industry which ought to be solely and truly a British one.

In illustration of his point Mr. Levinstein mentioned the fact that a new organic acid was invented by a large chemical firm in Germany. That firm did not know what to do with it. Three years afterwards another chemical firm in Germany made an important use of it. The inventor brought an action against them, but the German Government upset the patent. The Government said that the first inventor did not know what to do with his patent, and it was therefore of no use to commerce and industry. But in England the monopoly of the original firm was maintained. They never manufactured an ounce of acid in England, but they threatened with proceedings any English firm that produced the article. The consequence was that our chemists here were prevented from using this acid in new combinations, and thus our inventors' genius was stifled. Our manufacturers were prevented from producing it, whilst in Germany the invention was common property. A very important industry had, in Germany, been based on this acid, but here manufacturers up to this date could not use it. It was an example of unfairness in our patent laws.

Dr. SCHUNCK, in proposing the health of Mr. Levinstein, said the day had been one of great enjoyment; it had been an intellectual day. It was most interesting to have seen what was in progress in these large and extensive works.

Mr. THOS. TYRER said he had never heard the case for British manufacturers, and why they were a step or two behind, but so well as it had been by Mr. Levinstein. There were schools admirably fitted in the country, but few schools in which quite a complete chemical training was given, including physics. Those things were wanted if they were to cope with foreign competition, and meet future needs. He regarded it as a thousand pities that Hofmann was ever allowed to leave England. We were mean in the extreme to let him go. If he had stayed our patent laws would not have been what they were to-day. In conclusion he proposed the health of Dr. Schunck and Sir Thos. Wardle.

Dr. SCHUNCK said he hoped to attend many meetings of the Society, but he was afraid, at his age, the probabilities were against it.

Sir THOMAS WARDLE said that we could only export two millions sterling of silk from this country, while we had to import 20 millions from the Continent. Manchester was the only place in which their silk students could get a proper curriculum, and without more of such institutions as the technical school, the industry would not be restored to them. Collateral chemical industries would flourish if only the silk manufacture were restored.

Mr. LEVINSTEIN proposed "The Manchester Corporation."

Mr. Alderman Hoy, in responding, said the new technical school the Corporation was building was large—some thought too large, but he was convinced that it was not more than adequate to the present and prospective needs of that great industrial centre. In regard to the remarks of Sir Thos. Wardle, while they had not been able to give him all the encouragement he wanted, they yet had done much to meet his views.

Prof. W. H. PERKIN, F.R.S., whose health was toasted, said he was grateful for the remarks made about his father. It was to be hoped that the coal-tar industry would come back to this country. It was perfectly useless for a man to send his son for three years as a student in chemistry. The least period was five years. The money laid out on a student for six or seven years would be well repaid. That he would ask the company to bear in mind. In that time a student would have a good grasp of the subject, and in the works the advantage to him and to the manufacturer would be enormous.

Mr. LEVINSTEIN proposed the health of Mr. Tyrer, who, he said, had given more time to the establishment and development of the Society than any other member. Also he proposed the health of Mr. G. E. Davis, who had done great service.

Mr. TYRER and Mr. DAVIS responded. Mr. A. H. ALLEN made a humorous reply to the toast of his health, and Mr. CARTER BELL also had response to make for his energetic services.

#### MR. COUNCILLOR FRANKENBURG'S GARDEN PARTY.

In the afternoon a large company assembled at Overbrook, Kersal, and were received by Mr. and Mrs. Frankenburg. In the grounds and also in the drawing-room, refreshments were provided for the visitors, and in a marquee an excellent band performed a selection of music. This gathering, aided by the continued splendid weather, formed a most happy conclusion to the week's proceedings, and enabled all, not only to compare notes on the events of the week, but afforded an opportunity for a general leave-taking amid most pleasant scenery and surroundings.

## I.—PLANT, APPARATUS, AND MACHINERY.

### PATENTS.

*Evaporating Solutions [Brine, &c.] with Multiple Effect, Impts. in and Apparatus for.* T. Glover and J. Brock, both of Exchange Buildings, Liverpool. Eng. Pat. 14,952, July 6, 1896.

The first part of the apparatus comprises a flat-bottomed, covered pan, in which the liquid is heated by a fire, or by a steam coil, the steam from this vessel being employed to evaporate the liquid in the second part of the apparatus. The latter consists of three superposed chambers, the uppermost and lowest of which are connected by a series of pipes passing through the middle chamber. The liquid is contained in the uppermost and lowest chambers and in the pipes, and the steam from the first apparatus is admitted into the middle chamber around the pipes. Currents of air are passed upwards through the pipes from the lowest chamber, to obtain the effect of ebullition without raising the liquid to the boiling point. The third part of the apparatus consists of a vessel or a series of vessels containing the liquid, and each provided with a coil of pipes, through which the air and uncondensed steam from the second apparatus are passed. The primary evaporation takes place in the third apparatus, and the final evaporation in the first apparatus, the liquid and steam being passed through the multiple effect in opposite directions. The apparatus is provided with suitable agitators, and with scrapers and elevators for the removal of the deposited salts.—R. A.

*Evaporating Apparatus [for Glycerin, Salts, &c.], Impts. in and relating to.* J. Foster, Pollokshields, Glasgow. Eng. Pat. 17,053, August 1, 1896.

The vapour chamber of a vacuum evaporating apparatus is provided with a number of hinged or movable plates, each of which is provided on its under surface with a series of perforated baffle plates adapted to trap and return any glycerin, &c. which may be carried off with the vapours. The inclination of the hinged plates can be adjusted to any desired angle, or they can be turned into a vertical position to facilitate cleaning, &c. When salts are deposited by the evaporation, a hopper chamber and valves are provided at the lower end of the evaporator, with a trapping chamber and pipe connection to the vapour chamber, to permit the removal of the salts without admitting air to the evaporator.—R. A.

*Distilling, Evaporating, or Concentrating Liquids [Sugar Solutions, Fats, Oils, Acids, Saline Solutions, &c.], Improved Process and Apparatus for.* W. P. Thompson, 322, High Holborn, London. From A. Testelin, Brussels. Eng. Pat. 7108, March 18, 1897.

The process described by the patentee provides for the production of a maximum of vapour (as it appears at the commencement of violent ebullition) in the previously heated liquid, by bringing the liquid by mechanical means into the state of spray (with or without the application of steam) before or after its entrance into the evaporation, distillation, or concentration space, so that the escape of the steam bubbles or of the easily volatilised constituents of the liquid takes place upon a surface increased to its maximum by the division into spray. In the apparatus described, the heat of the escaping vapours is utilised for the preliminary heating of the liquid before its entrance into the spraying apparatus, and the spraying is effected by means of an injector. Steam can also be admitted for heating the liquid, either at the commencement of, or during, the spraying process, as may be required.—R. A.

*Cooling, Concentrating, Evaporating, and Graduating Liquids; Impts. in Apparatus for.* J. Klein, Frankenthal, German Empire. Eng. Pat. 9941, April 21, 1897.

The apparatus is of the kind in which the liquid is passed downward through or over successive layers or bundles of brushwood, &c., the bundles in the lower layers being made of greater length than those in the upper layers, to prevent

liquid from dropping from the ends of the upper bundles directly into the receiver. The bundles are also arranged to break pitch vertically, the supporting rods for the bundles being arranged in the form of trellis-work.—R. A.

*Cooling Liquids [Water, &c.], Impts. in and connected with Apparatus for.* J. Klein, Frankenthal, German Empire. Eng. Pat. 10,025, April 22, 1897.

IMPROVEMENTS are described in the specification of Eng. Pat. 11,246 of 1890 (this Journal, 1890, 1024), in which the liquid is run downward between ranges of plates set at different angles, and is cooled by a current of air passed upward between the plates. In the present invention the whole or part of the ranges of cooling plates are arranged within a pit, to reduce the lift necessary for the liquid to be cooled, the plates within the pit being enclosed, except at the bottom, by open or close boarding or walling. Each lower range of plates is made of greater length than the range above, and the projecting wings are covered with hinged pent-roofs. The plates are constructed in grid form, the lowest member of the grid being notched beneath, so that the edges formed by the notches conduct the liquid directly on to the edges of the plates beneath. The top edge of the grid is provided with a narrow notched trough, through which the liquid is delivered on to the plates. The cooling plates are surmounted by a chimney-like structure adapted to induce a current of air through the apparatus.—R. A.

*Vapour Condensers, and Apparatus for Destroying Noxious Fumes, Recovering By-Products, from Distillation, and like Purposes; Impts. in.* S. G. Merriek, Philadelphia, and H. L. Washburn, U.S.A. Eng. Pat. 12,572, June 8, 1896.

THE apparatus consists of a chamber divided into two compartments by a partition, which, however, does not reach down to the floor of the chamber. Suitably suspended in the chamber is a rotary conveyor consisting of a frusto-conical casing having spiral vanes which extend from the axis to the sides of the casing, the smaller end of the casing working in an opening or stuffing box in the partition.

Water or other solution is placed in the chamber to just above the level of the axis or shaft, so that on rapid rotation of the conveyor, fumes or gases in one compartment are drawn into the casing and forced along with the water into the other compartment, whence they escape.

A modification is also described, in which the vanes are replaced by a spiral pipe.—O. H.

*Condensing, Absorbing, Heating, Distilling, and otherwise Treating Gases [Benzol, &c.], and Liquids; An Improved Column for.* H. Hirzel, Leipzig-Plagwitz, Germany. Eng. Pat. 2900, Feb. 3, 1897.

THE column comprises a series of superposed chambers or dishes, each provided with an arrangement of pipes adapted to receive or circulate the cooling or warming gases or liquids, the pipes in each chamber being either in communication with those of adjacent chambers or forming a separate series for each chamber, and in conjunction therewith a direct steam inlet arranged below the lowest dish of the column, to serve for the admission of steam for distilling, &c. purposes.—R. A.

*Smoke or Noxious Gases or Vapours, An Improved Respirator or Protective Device for Preventing the Inhalation of.* C. A. A. Miller, Syracuse, New York, U.S.A. Eng. Pat. 5512, March 2, 1897.

THE respirator consists of a mask of non-combustible material in a suitable frame, and provided in the front with a sighthole protected with mica, &c., and with a perforated cup or holder to receive a sponge, &c., through which respiration is effected. The mask has a gathered or elastic backing, to enable it to be fitted closely to the head, and may be secured in position by a strap at the back.—R. A.

*Reducing the Pressure of Liquids and Gases, Improved Apparatus for.* R. Matchett, Melbourne. Eng. Pat. 4762, Feb. 22, 1897.

A FLEXIBLE diaphragm of rubber, &c., is employed. It controls a valve on the inlet pipe of the apparatus. Spiral springs and plates bearing against each side of the diaphragm enable the pressure to be reduced or adjusted as may be desired. The apparatus is also fitted with a safety-valve and pressure-gauge.—O. H.

*Drying Moist Materials, A Method of and Apparatus for.* E. Stauber, Berlin, Germany. Eng. Pat. 9665, May 6, 1896.

THE moist material—peat, for example—is first pressed, and then fed into a revolving drum fitted with spiral vanes on the inside. Through this revolver pass the direct products of combustion from a steam-boiler furnace. After passing through this apparatus the material is lifted by an elevator (and, during its passage through the open air, cooled) into a steam drying apparatus, heated by means of superheated steam generated and superheated in the boiler and revolver. The material is carried through the apparatus on travelling bands and laths.—O. H.

*Filtering Apparatus, Impts. in.* S. K. Welch, London. Eng. Pat. 11,633, March 28, 1896.

A FRAME or table is employed, on which is stretched perforated metal or wirework, and beneath which is a shallow tank connected with an air pump. An endless band of filtering material, suitably carried on rollers, rests on the perforated metal work, so that on lowering a frame of about the same dimensions as that on which the metal sheet is stretched, a shallow tank is formed with a porous bottom. Into this tank passes the liquid to be filtered, the filtration being expedited by the air pump. When the pores of the cloth become choked, a fresh portion of the band is used, the previously used and fouled portion being in the meantime cleaned and freed from the deposit.—O. H.

*Gas [Oxygen, Hydrogen, &c.] or Gaseous Fluids under Pressure, Impts. in Cylinders for Storing.* W. Lawson, Newton-le-Willows, Lancaster, and T. Prescott, Sale, Chester. Eng. Pat. 13,331, June 17, 1896.

CYLINDERS for storing and conveying compressed gases and the like are constructed of corrugated metal, fluted either longitudinally, diagonally, or with transverse corrugations, and are provided—in addition to the ordinary inlet and outlet valve—with a regulating or safety valve, whereby any excessive pressure sufficient to cause an extension of the cylinder is automatically released. The exterior surfaces of the corrugations may be protected by india-rubber or other flexible coverings.—R. A.

*Cooling Water and other Liquids, Impts. in Apparatus for.* D. Halpin, Victoria Street, London, J. B. Alliot, Bloomsgrove Works, Nottingham, and L. Sterne, Victoria Street, Westminster, London. Eng. Pat. 11,321, May 23, 1896.

THE liquid to be cooled is made to issue under pressure in the form of finely divided jets from ejection nozzles, which are arranged in conjunction with induction nozzles at the bottom, &c. of an open tower or chimney, &c., so as to cause induced currents of cold or cooler air to be brought intimately into contact with jets of liquid, to take up the heat therefrom.—R. A.

*Still-worm Pipes, and Supports for the same, Impts. in.* Edwards and Co., London. From L. Rohrmann, Krauschwitz, Germany. Eng. Pat. 1658, Jan. 21, 1897.

THE inventor claims “the combination, with helical earthenware still-worm pipes, of short supports in which the separate coils of the pipes rest, the supports having double feet and being entirely separate from each other, and the upper part of each support being separate from the lower part.—V. C.

## II.—FUEL, GAS, AND LIGHT.

*Benzene, and its Importance as an Illuminating Agent.* G. Kraemer. Chem. Zeit. Rep. 1897, 21, 136.

THE coal tar from the gasworks in Germany is said to be the source of about three-eighths of the total consumption of benzene in that country, the remainder being imported from abroad—chiefly England. Much attention has been given within recent years to the production of coke in closed ovens, provided with means for recovering the by-products, the benzene contained in the gas being extracted by absorbing it in heavy tar oils, from which it is subsequently liberated by distillation. At the beginning of last year the quantity of benzene thus produced was put down at 4,500 to 5,000 tons per annum, which is said to represent three times the amount obtainable from the tar; so that, as regards their supplies of this material, the German colour works will soon be quite independent of foreign sources. The rapid advance in the price of benzene last year gave rise to the reconstruction of a large number of coke ovens, and it is estimated that when these, and others for which plans have been prepared, are started, at least 80,000 tons of benzene will be produced. As this quantity cannot possibly be consumed, even if, in addition to the colour industry, it were used for increasing the illuminating power of gas, the author suggests that it should be employed as a direct lighting agent. Trials made with xylene in an incandescent spirit lamp have given the following results:—

	Candles.
95 per cent. alcohol .....	6,100
Mixture of 15 per cent. xylene and 85 per cent. alcohol	6,700
"    25    "                    "    75    "    "	7,200
"    33½    "                  "    66½    "    "	8,226

For incandescent lamps the first proportion should not be exceeded, otherwise the mantle is blackened. Commercial 90 per cent. benzene gives equally good results. With regard to the illuminating effect, it is shown that for every 100 parts of alcohol *per se*, only 81.4 parts of mixture are required when adding 10 per cent. of xylene, and 73.2 parts when 15 per cent. is added. The latter represents a saving of 26.8 per cent., assuming the price of the mixture to be the same as that of denatured alcohol. In case of need a mixture of 66½ per cent. of alcohol and 33½ per cent. of benzene can be used in ordinary petroleum lamps in the place of petroleum.—D. B.

*Gas-Igniting Appliances, Automatic.* H. Drehschmidt. J. für Gasbeleucht. 1897, 40, 297—301.

ELECTRICAL appliances for igniting gas automatically are either complicated or cumbersome. Platinum sponge glows in a stream of hydrogen and air, and effects ignition. The hydrogen being much diluted in coal-gas, the latter cannot be thus ignited. The sponge, however, becomes sufficiently heated to warm a platinum wire embedded in it, so that the latter is made incandescent by the gas, and ignites it. Platinum sponge soon loses its activity, and Duke substituted for it, platinised meerschaum or other porous material, with good results. A pellet of this material with a protruding platinum wire, if suitably fixed with regard to the slit of a flat-flame burner, will ignite the gas whenever the gas-tap is opened, and will retain its efficiency for a long period, provided the wire is not displaced in cleaning.

This device is less readily applied to incandescent burners, as, if suspended above the mantle, it becomes spoilt by the hot gases. S. Elster placed the pellet above a special jet at the side of the burner, and by careful manipulation of a two-way cock he was able to first ignite the flash-jet, to ignite therefrom the principal flame, and then to extinguish the flash-jet. The intelligent manipulation of the gas-cock, which was essential to its proper working, rendered this device valueless for general use. Canellopoulos extinguished the flash-jet automatically through the expansion of a solid, a liquid, or a gas, by the heat of the principal flame. In the first application of his patent, the expansion of gas, confined in a sealed limb of a U-tube, forced mercury from the bend of the tube up the other limb, which terminated in the flash-jet. The

mercury sealed the gas inlet to this limb, and thus extinguished the jet very soon after the ignition of the principal flame. This arrangement was faulty, in that the gas flowed simultaneously to the jet and the burner, and collected in the chimney before the jet was lighted by the pellet; and thus the principal flame was ignited with an explosion which damaged the mantle. The expansion of platinum wire was then made to actuate a two-way valve on the gas supply. The normal position of the valve left the way to the flash-jet only open. On opening the gas-tap, gas therefore flowed to the latter and was ignited by the platinised pellet. The heat of the flash-flame expanded a platinum wire which supported a lever attached to the valve-plug, and its expansion partially opened the way to the burner. The principal flame ignited from the flash-jet and further expanded the platinum wire, thereby closing the way to the jet and extinguishing it. When the burner was extinguished, the contraction of the wire automatically brought the valve to its original position. A failure on the part of the pellet to ignite the gas is not dangerous, as only the small quantity of gas for the supply of the flash-jet can escape to the air.—J. A. B.

*Sulphur and Hydrogen, Conditions of Direct Combination of.* H. Pélabon. Comptes Rend. 1897, 686.

See under VII., page 610.

*Illuminating Gas, Determination of Oxygen in.* O. Pfeiffer. J. für Gasbeleucht. 1897, 40, 354.

See under XXIII., page 635.

## PATENTS.

*Ovens for Drying and Burning Tiles, Pottery, and other Plastic or Semi-dry Ware; Impts. in.* R. Stanley, Nuneaton, Cheshire. Eng. Pat. 7899, April 14, 1896.

AN oven or kiln, having a chamber underneath the floor in direct communication with the fire-holes, and openings leading from the chamber through the floor into vertical flues. The floor of the oven is carried upon fire-bricks arranged in such a way that the fire from the fire-holes may collect and combine. A casing is employed between the walls of the oven and the goods to be burnt, forming a flue or flues down which the fire, after having passed up the vertical flues, may descend and be led off to an outside chimney.—V. C.

*Metallic Threads, Refractory [Incandescent Gas-burners]; Impts. in or relating to the Manufacture of.* M. L. Ross, London. From E. Oberlé, Paris. Eng. Pat. 12,056, June 2, 1896.

THIS specification refers to the preparation of oxide threads for incandescent gas-burners. A 50 per cent. solution of thorium oxychloride ( $\text{ThOCl}_2$ ) in alcohol is mixed with a 3—20 per cent. solution of nitrocellulose in alcohol-ether if the thread is to be spun under water, or with a 20 per cent. solution if it is to be spun under pressure in the air. The oxychloride may be spun when mixed with one-fourth part of nitrocellulose. The proportion of alcohol must exceed that of ether in a homogeneous solution, because ether precipitates  $\text{ThO}_2$  or a basic salt. The spinning is effected with either a weak or a strong solution. In the former case the solution is passed through glass tubes with capillary openings immersed in water, the solution being drawn by clockwork or otherwise through the water, in which the alcohol and ether dissolve; the thread is then dried in the air. In the latter case, the solution, consisting of 20 per cent. of nitrocellulose and 80 per cent. of thorium oxychloride,  $\text{ThOCl}_2$ , with 0.75 of cerium oxychloride, dissolved in ether and alcohol, is passed under pressure into the open air. The threads are finally decomposed by heating in a closed vessel or in the open air at a low temperature, whereby the nitrocellulose is burned and the salts are broken up into oxyhydrates, which are then converted into oxides by means of a Bunsen burner. The threads may be denitrated by means of ammonium hydrosulphide if preferred. By using a salt that may be metallised, in place of thorium compounds, threads for incandescent electric lamp filaments may be made in the same manner.—W. G. M.

*Incandescing Media for Lighting Purposes, Impts. in the Manufacture of.* R. Langhans, Berlin. Eng. Pat. 14,845, July 4, 1896.

THE claims are for the manufacture of incandescence media composed of zirconia with about 1 per cent. of vanadium pentoxide. Mantles may be made in the ordinary way by impregnating a fabric with an aqueous solution of zirconium and vanadium salts, and then burning off; or a zirconia body may be first made (say according to Eng. Pat. 22,396 of 1893), then impregnated with an aqueous vanadium solution and calcined. A paste may be made by impregnating zirconia with an aqueous vanadium solution, and the bodies made from this paste are then dried and calcined in a Bunsen flame.—H. B.

*Filaments for Use in Electric Glow Lamps, Impts. in. [Impregnation with Rare Earth Oxides.]* F. de Mare, Paris, France. Eng. Pat. 16,534, July 25, 1896.

THE improved filament is formed of a vegetable fibre or thread impregnated with an aqueous solution of an organic salt of one or more of the rare earths, the object being to obtain a mixture of carbon and the oxide of the rare earth, the latter acting as the irradiating substance, and the former as the conductor of electricity. The solution preferably employed is one of the citrates obtained by precipitating with ammonium citrate, a solution composed of thorium nitrate and cerium nitrate, the proportions being 99 per cent. of the oxide of the former, and 1 per cent. of the oxide of the latter. The carbonised filament is soaked a second time in the solution, and then dried and annealed electrically. Instead of the soaking, a mixing process may be employed, in which the organic salt is mixed with the vegetable substance before it is drawn into a filament, the latter being then soaked several times in the solution of the salt, and annealed as before.—G. H. B.

*Incandescence Bodies for Illuminating Purposes, Impts. in the Manufacture of.* W. Nicholls, London. Eng. Pat. 16,966, July 30, 1896.

MANTLES are to be prepared in the ordinary way by impregnating a fabric with a solution prepared as follows:—“2 grms. of palladium chloride dissolved in 100 grms. of water and 3 grms. of platinum chloride dissolved in 100 grms. of water are each mixed with 25 grms. of tartar emetic, and 25 drops of each or 50 drops of their mixture are added to a solution consisting of” 12·5 grms. of zirconium nitrate, 6·25 grms. of calcium nitrate, and 8·5 grms. of ammonium nitrate. Other suitable soluble salts of zirconium, calcium, and antimony may be used. It is stated that a mantle so prepared, if placed on a Bunsen burner, will ignite the gas when the latter is turned on. The claims are for “a self-igniting incandescence body” and for the above-described impregnating solution.—H. B.

*Incandescent Light produced from Benzine Gas. An Apparatus for Producing and Using an.* P. W. von Gehlen, Prussia. Eng. Pat. 2194, Jan. 27, 1897.

THE single claim is for “an arrangement for the production of benzine gas incandescent light, characterised by the fact that compressed air is forced over the surface of benzine, and becoming impregnated with hydrocarbon thereby, flows to an incandescence gas-light burner of which the annular cone surrounding the nozzle is solid or imperforate.” The “annular cone surrounding the nozzle” is not perforated with air inlets, because the gaseous mixture contains sufficient air for combustion.—H. B.

[Mantles.] *Incandescent Gas Burners, Impts. in.* D. Meyer, Paris. Eng. Pat. 8759, April 6, 1897.

THE improved burner consists of incandescence material, which is formed into beads or particles of any suitable shape, these being strung upon a double wire and arranged in network form over a Bunsen burner, so as to form a mantle. The air inlets of the burner are much larger than usual, and are fitted with wire gauze.—H. B.

*Bunsen Burners and Incandescent Gas and Similar Lamps in which such Burners are Incorporated, Impts. relating to.* A. H. Catherwood, Bermondsey. Eng. Pat. 11,106, May 21, 1896.

THE combination illustrated and claimed, is that of an incandescence lamp of the usual type, with a globe surrounding the chimney, the globe resting upon a gallery which forms the upper part of an imperforate casing that surrounds the burner and passes down to a point below the air-inlet holes, where it is fastened by an air-tight joint to the burner tube. Thus the air supply—both that portion which enters by the air-inlet holes and that which passes in at the bottom of the chimney—must all pass down between the globe and the chimney, receiving a preliminary heating, and being unaffected by draughts. Another claim is for a device consisting of a tubular piece of glass filling up the space between the “lighting-back” plate and the lower edge of the chimney; in this way no air can enter at that point, and the entire air supply must enter through the air-inlet holes.—H. B.

*Incandescence Spirit Lamps, Impts. in.* E. Becker, Berlin. Eng. Pat. 10,710, May 18, 1896.

THE improvements relate to lamps of the type in which a small heating flame from a central wick, vaporises the spirit which is drawn upwards from the reservoir by two or more main wicks, the tops of the latter being in the gasifying chamber. The improvements are embodied in the claims, which are for a spirit incandescence lamp in which the heating gases of the vaporising flame pass through the Bunsen burner by means of a central pipe serving as a draught cylinder and passing through the gasifying chamber, and are led by a lateral branch pipe up into the chimney surrounding the mantle burner; the objects being to avoid smell, to heat the mixture of gas and air, to keep external parts cool, and to give a steady flame when the lamp is carried about.—H. B.

*Acetylene, Treating Prior to Combustion; Impts. in and connected with the Method and Apparatus for.* T. Thorp, Whitefield, near Manchester, and T. G. Marsh, Manchester. Eng. Pat. 12,942, June 12, 1896.

THE invention refers to methods of and apparatus for diluting acetylene with air or other gases for the supply of ordinary gas burners at low pressure. Acetylene at a pressure of about 6 ins. of water, feeds an injector which draws in the diluent, and the mixture is stored in a low-pressure holder, the bell of which actuates a tumbler arrangement which opens or closes the valve on the injector inlet pipe as required. Or the acetylene drives a motor—preferably of gas-meter type—which pumps the diluent along with the exhaust acetylene into a mixing chamber.—J. A. B.

*Acetylene Gas, Impts. in Automatic Apparatus for the Manufacture of.* J. E. Atkinson and J. M. Labonehere, both of Liverpool. Eng. Pat. 13,147, June 15, 1896.

TWO generators, automatically acting in succession, are supplied with water from a reservoir through a non-return valve. A gasometer and safety devices are provided. In another pattern the carbide is placed in a receptacle within the gasometer, which has a dished top, with door and seal for the introduction of fresh carbide. In a portable pattern, the bell of the gasometer is weighted so that it does not rise.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Generating, Storing, and Cooling.* F. S. Thorn and C. Hoddle, both of London. Eng. Pat. 15,962, July 18, 1896.

CLOSE cylindrical carbide containers with external mouth-pieces are situated at the foot of the tank of a gasholder. The fall of the gasholder bell opens a ball cock, and permits water to enter one compartment of one container. As each compartment is exhausted, the water flows on to the next. When one container is exhausted, another ball cock operates and admits water to the next container.—J. A. B.

*Acetylene, Apparatus for Generating and Storing.* G. de Roussy de Sales, Lyons, France. Eng. Pat. 2292, Jan. 28, 1897.

A CLOSE vessel contains a fixed bell with contracted upper part. The water in the bell acts, until its level is depressed by the gas produced, on carbide introduced in cartridges into projecting receivers, which can be shut off from the bell by valves. The gas passes through a non-return valve and washer to an elastic bag, and thence to the burner. Safety devices are provided.—J. A. B.

*Acetylene Gas, Impts. in Means for Generating, Holding, and Burning.* Don Carlos B. y Franco, San Gervasio, near Barcelona. Eng. Pat. 5236, Feb. 26, 1897 (under International Convention).

THE invention comprises a fixed or portable gasogene consisting of two connected reservoirs for water, the lower of which contains a carbide chamber, to which the water gains access by means of wicks of any porous material.

—J. A. B.

*Acetylene Gas, An Improved Apparatus for the Manufacture of.* H. E. Alexandre, Barcelona, Spain. Eng. Pat. 5913, March 5, 1897.

THE apparatus consists of a generator with vertically separated compartments which come into action successively; a bell gasholder with rack which operates the water-supply tap to the generator; a gas-inlet pipe sealed in the water of the gasholder tank, so that the passing gas is washed; and a signal device giving notice of the exhaustion of the carbide.—J. A. B.

*Acetylene, Impts. in Apparatus for Manufacturing.* H. Cousin, Paris. Eng. Pat. 8552, April 3, 1897.

A STATIONARY hopper containing carbide is supported above a gasholder bell which floats in an annular tank. To the bottom of the hopper is attached a small bell which dips in an annular tank riveted to the crown of the gasholder bell. The valve at the bottom of the hopper is kept closed by means of springs, until the weight of the gasholder bell in its lowest position is thrown upon it, when it is opened and carbide drops through into water at the base of the apparatus. The gas is purified in four compartments, containing, in order, sulphate of copper, oxide of iron, carbide of calcium, and chloride of calcium.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Developing.* W. P. Thompson, Liverpool. From The Deutsche Acetylen-Gesellschaft mit beschränkter Haftung, Berlin. Eng. Pat. 10,199, April 23, 1897.

A GASHOLDER bell supporting a carbide container moves in the annular space between two concentric tanks, the inner of which contains water for the decomposition of the carbide. An air lock for admission of carbide is provided.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Generating.* D. C. Morency, Levis, Canada. Eng. Pat. 10,186, April 23, 1897.

THE gas is generated by water admitted to carbide through the top of a vessel of bell gasholder pattern. It escapes to a bell gasholder, in the crown of which is a subsidiary holder, the bell of which operates its inlet valve. Burners are supplied from this subsidiary holder. Depression of the level of the liquid in the main holder cuts off the supply of water to the generator.—J. A. B.

*Carbides of the Earth Metals and Alkali Earth Metals, Impts. in the Manufacture of.* L. M. Bullier, Paris, France. Eng. Pat. 16,255, July 22, 1896.

IN the improved process for the commercial manufacture of carbide of calcium, or of any of the carbides of the earth metals and alkali earth metals, the temperature at which fusion takes place is lowered by the addition of some suitable flux, such as 10 per cent. fluor spar, fluoride of aluminium, cryolite, or other fluxes, such as alumina, silicates, &c., according to the nature and purity of the carbide required. The process may be carried out by the

method described in Eng. Pat. 2820, Feb. 8, 1895 (this Journal, 1896, 265), or by any other method, whether electrical or otherwise.—C. H. R.

*Treatment of Gas for Illuminating and other Purposes, Impts. in and relating to the.* A. Arter, Hammersmith. Eng. Pat. 12,630, June 6, 1896.

THE gas is dried and expanded before passing to the burners. This is done by passing it through a vessel heated by one or more ordinary gas burners.—R. S.

*Removal of Sulphuretted Hydrogen from Gases or Gaseous Mixtures, An Improved Process and Apparatus for the.* H. Strache, Vienna. Eng. Pat. 11,913, July 6, 1896.

THE sulphuretted hydrogen is removed by means of nitric acid, nitrous acid, or oxides of nitrogen, with or without the addition of air or oxygen. The best plan, it is stated, is to have three vessels arranged at different levels. The gas to be treated, mixed with air, is led into the lower vessel, in which it is treated with dilute nitric or nitrous acid, which is the mixture which runs away from the third vessel. It then passes to the second vessel, in which it is treated with concentrated nitric acid, and is finally washed with water in the third or uppermost vessel. The sulphuretted hydrogen is recovered as sulphur from the vessels and discharged liquid.—R. S.

*Manufacture of Gas, and Apparatus therefor; Impts. in the.* W. L. Wise, London. From Prof. E. Thomson, Swampscott, U.S.A. Eng. Pat. 16,692, July 28, 1896.

TO manufacture a combustible gas consisting mainly of carbon monoxide, hydrogen and nitrogen, a vertical, lined gas producer, having a vertical central division rising some distance from the base, is employed; or two such chambers connected together near their upper ends may be used. Instead of the usual bricks employed as regenerative material, or in addition thereto, the ashes of the fuel used in the chambers are employed. Air is passed through this heated incombustible inert material, thence upwards through a mass of combustible fuel, over the top of which water is discharged. The gases produced are then drawn downwards in the second portion of the chamber (or the second one when two are used), through the incandescent fuel and ashes therein, thereby abstracting the heat therefrom; and finally the gaseous mixture is collected, or used at once in a gas engine. The direction of inflow of air and outflow of gas is reversed from time to time, either automatically or by hand. The two forms of producer are illustrated, showing suitable valve mechanism, and, in the case where two chambers are employed, the connections with the gas engine to be driven, and the mechanism for operating the reversing valves automatically from that engine.—R. S.

*Condensing, Absorbing, Heating, Distilling, and otherwise Treating Gases [Benzol Vapours, &c.] and Liquids An Improved Column for.* H. Hirtzel, Leipzig-Plagwitz Germany. Eng. Pat. 2900, Feb. 3, 1897.

See under 1, page 602.

*Producer and Water-Gas, Improved Process and Apparatus for Manufacturing.* C. Whitfield, Kettering. Eng. Pat. 12,771, June 10, 1896.

PRODUCER gas having the smallest percentage of nitrogen, and a high percentage of carbonic oxide, hydrogen, and of the lighter hydrocarbons, is obtained by raising the fuel at the bottom of a generator or producer to a high temperature by forcing in air, and by injecting into the incandescent fuel, at a point above the combustion zone, steam and the volatile compounds given off from the green fuel at the upper part of the generator. The products of combustion of the fuel and of the decomposition of the steam and the volatile products, are withdrawn from the producer at a point—say 2 or 3 ft.—below the top of the generator and below the point where the volatile compounds are given off from the green fuel. The latter are withdrawn through a suitable connection pipe, and are passed into the column at another point along with the steam of the steam injector.

—R. S.

*Gas Furnaces, Impts. in.* T. Fletcher, and Fletcher, Russell, and Co., Ltd., Warrington. Eng. Pat. 7067, March 18, 1897.

THE gaseous fuel employed, is composed of air under pressure mixed with a light hydrocarbon, such as gasoline or benzoline. For an oxidising flame, the air is not fully saturated with hydrocarbon; for a reducing flame, it is supersaturated. The mixture is caused to come into direct contact with the material to be heated, and is injected at a tangent to the inner diameter of a ring or cylinder enclosing the articles to be heated.—R. S.

*Enriching Gas, An Improved Composition and Apparatus for.* A. A. Stephenson. Sydney, New South Wales. Eng. Pat. 7991, March 29, 1897.

THE composition consists of  $\frac{1}{2}$  of a pint of oil of cloves, 2 pints of "best ether," 2 pints of petroleum, 2 pints of gasoline, and 2 pints of kerosene, mixed with the following dry substances:  $\frac{1}{2}$  lb. of powdered camphor,  $\frac{1}{2}$  lb. of powdered resin,  $\frac{1}{2}$  lb. of powdered whiting, and  $\frac{1}{2}$  lb. of powdered glue. The enriching apparatus, which is charged with the above composition, and through which the gas is passed, consists of a box having inlet and outlet unions, a charging hole, and, in its interior, rows of wires for supporting canvas, wicks, or other similar absorbent material.—R. S.

*Lighting and Heating by Means of Hydrocarbons, Apparatus for.* S. Pitt, Sutton, Surrey. From La Compagnie Internationale des Procédés Adolphe Seigle, Paris. Eng. Pat. 8177, March 30, 1897.

THE apparatus, which is specially applicable to heating steam boilers by the use of light or heavy liquid hydrocarbons, consists, 1st, of a retort in which the hydrocarbons are gasified; 2nd, a sprayer (optional); and 3rd, a permanent lighter placed between the jet and the furnace to be heated. The retort is a cylindrical vertical column, through the hollow walls of which, or through a helical tube arranged inside the wall, the hydrocarbons are passed from above downwards, and provided with a lamp in its lowest part, which at first is fed with an easily inflammable light hydrocarbon, but afterwards solely by some of the vapour produced. The sprayer is omitted when using light hydrocarbons. The lighter is a casing having an inner metallic or refractory wall, which slightly pinches the gas, while its axis is coincident with that of the flame.—R. S.

*Furnaces for Use with Light Hydrocarbons as Fuel, Impts. in.* T. Fletcher, and Fletcher, Russell, and Co., Ltd., Warrington. Eng. Pat. 9042, April 9, 1897.

THE furnace, to be used instead of a muffle or the like, is circular in plan, with any suitable centrally perforated cover. In the centre of the furnace bottom there is a movable or permanent circular wall, or a flat-bottomed, open-topped, cylindrical container, leaving an annular passage between it and the circular wall. Into this annular passage the benzoline or gasoline flame is injected, through an opening in the furnace casing at a tangent thereto. The work—such as enamels and dentists' work—is placed in the inner container or space.—R. S.

*A Photometer for Automatically Measuring and Registering the Intensity of the Light of a Gas Flame, and Apparatus therefor.* W. and B. Cowan, Ltd., Westminster. From C. V. L. Martenson, Rio de Janeiro. Eng. Pat. 1041, April 9, 1897.

See under XXIII., page 634.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Petroleum, Caucasian; New Constituents of.* W. Markownikoff. Ber. 30, [8], 974—977.

CONTRARY to his previously published opinions (J. Russ. Chem. Soc. 1890, 23), that the fractions boiling below 60° C. consist exclusively of paraffins, the author now finds that in some of these the specific gravities are higher than

is consistent with this assumption, and indicate the presence of cyclic hydrocarbons. This is the case with the fractions boiling between 58° and 48°, and from 87° to 81°, where the sp. gr. rises continuously as the boiling point recedes; and since in the fraction 68°—70°, the sp. gr. is 0.692, whilst that of normal hexane is 0.663, and in the fraction 36°—38° the sp. gr. is 0.643, that of normal pentane being 0.6263, it is assumed that the methylpentamethylene known to be present in the fraction 68°—73° is concentrated in the fraction 71°—75°, the presence of another cyclic hydrocarbon (trimethyltetramethylene or tetramethyltrimethylene) being conjectured in the fractions between 79° and 85°.

In the fraction 50°—51° the sp. gr. (0.751) indicated cyclopentane, the secondary nitro-product obtained from this fraction yielding the characteristic benzoyl derivative (glutaric acid) indicative of pentamethylene. From this and the adipic acid obtained by nitrating the hexamethylene fractions, it is concluded that the cyclic hydrocarbons having no branch are converted on oxidation into the corresponding dibasic acids.

The fraction 91°—93° (sp. gr. 0.730) was examined and found to contain a branch chain hydrocarbon,  $C_{11}H_{22}$ , yielding a tertiary nitro-product,  $C_{11}H_{21}NO_2$ , boiling at 131°—132°, the corresponding tertiary alcohol boiling at 144°—145°. In preparing the latter, an unsaturated hydrocarbon, which can only be  $C_{11}H_{20}$ , was also formed, and yielded, on prolonged heating with hydrogen iodide, a hydrocarbon distilling at 88°—93°, the polymerised products boiling at 94°—130° and 130°—240°. When refractionated, the bulk had a boiling point of 91°—93° and a sp. gr. at 4°—20° of 0.7231, with a vapour density of 3.45, this sp. gr. being lower than that (0.7543) found for synthetic dimethylpentamethylene by Zelinsky and Rudsky.—C. S.

*Petroleum, a South American; Composition of.* C. F. Mabery and A. S. Kittelberger. Amer. Chem. J. 19, [5], 374—381.

THE sample examined was obtained from the vicinity of the Magdalena River, in Colombia. The crude oil had a sp. gr. of 0.9480 at 20° C., with 0.70 per cent. of sulphur, about 0.320 per cent. of nitrogen, and 0.011 per cent. of ash (containing much iron); the percentages of carbon and hydrogen being 85.45—85.80 and 11.79—12.02 per cent. respectively, and the bromine absorption 12.09 per cent. The colour was dark and the consistency thick and viscous. On distillation under ordinary pressure, the first fractions came over at 260°, and the highest (those distilling between 310° and 345°) were badly cracked, as evidenced by the high bromine absorption (34.96 per cent.), thus differing from North American oils. *In vacuo* the first fraction passed over at 100° C., the largest individual fractions above that temperature being those at 140°—150° and 150°—155°. On repeated distillation, under atmospheric pressure, of the fractions up to 150°, the fraction collected at 170°—172° yielded a hydrocarbon approximating to the formula  $C_{10}H_{20}$ , and that at 190°—192° a hydrocarbon corresponding to  $C_{11}H_{22}$  (sp. gr. 0.8381) or  $C_{12}H_{24}$ . The next distillate of importance came over at 212°—214°: formula  $C_{12}H_{24}$ , sp. gr. 0.8483; and as the sp. gr. of the oil after treatment gave 0.8484—the same value as the crude distillate—it appears that this petroleum consists mainly of a single series of hydrocarbons (only a trace of aromatic hydrocarbons being present): the  $C_nH_{2n}$  series, similar to the naphthenes in Russian petroleum, which is the first instance noticed of such a constitution in American oils.—C. S.

### PATENTS.

*Ammoniacal Liquor, A Process for removing Carbonic Acid and Hydrogen Sulphide from.* A. Feldmann, Bremen, Germany. Eng. Pat. 10,501, April 27, 1897.

See under VII., page 611.

*Oil [Mineral], Impts. in the Process of and Apparatus for Deodorising.* J. R. Whiting, Connecticut, and W. A. Lawrence, New York. Eng. Pat. 10,526, April 27, 1897.

THE process is one for refining and deodorising the lighter products of the distillation of petroleum and coal, such as petroleum ether, gasoline, benzine, naphtha, &c.

The light oil is converted into vapour in a steam-heated boiler, the vapour then being forced by the pressure thus generated through a vertical cylinder packed with bone charcoal. After passing through this, the vapour is led into a cylinder charged with lime water, and is discharged into a condenser, from which it may be collected.—W. P. S.

#### IV.—COLOURING MATTERS AND DYES.

*Dyeoood Extracts in Powder.* Leipziger Farber-u. Zucht. Zeit. 46, [6], 244.

SERACH, fustic, and Persian berry extracts have recently been put on the American market in powder form. These extracts are said to be very pure, stable, and to effect a saving in carriage in cases where the articles have to be forwarded long distances.—I. S.

*o-Nitro-p-phenylene Diamine.* C. Bülow and E. Mann. Ber. 30, 977—988.

By the action of nitrite on nitro-*p*-phenylene diamine, Bülow (Ber. 29, 2284) observed that only one of the amido groups is attacked, even when a large excess of hydrochloric acid is present, and the second group is only diazotised after the first has been combined with some dyestuff component. In continuing their investigation of the substance, the authors find that with regard to acetylation with acetic acid or benzylation by the Schotten-Baumann method, substitution only takes place in one amido group. Nitro-diacetyl-*p*-phenylene diamine is obtained by nitrating diacetyl-*p*-phenylene diamine in sulphuric acid solution, and one acetyl group can be very readily removed by the action of very dilute alkalis or even ammonia. The nitro-acetyl-*p*-phenylene diamine is a weak base, which, however, gives a stable diazo compound. On combining this with  $\beta$ -naphthol disulphonic acid R and hydrolysing the product, a dyestuff is obtained isomeric with that produced from the non-acetylated base and R salt. Hence the acetyl group, which is not at first attacked, is attached to that amido group which is most easily acted on by nitrous acid, *i.e.*, which has the greatest basicity. By suitably reducing nitro-diacetyl-*p*-phenylene diamine, it is converted into *p*-diacetyltriimidobenzene, which, on treatment with nitrite in an acid solution, yields diacetylamidobenzene-azimide. This substance, even on standing in acetic acid solution at the ordinary temperature, loses the imido acetyl group and is converted into acetylamidobenzene-azimide. The dyestuff obtained by combining the diazo compound of nitro-acetyl-*p*-phenylene diamine with R salt crystallises in long, thin needles and is easily soluble in water. It dyes wool bluish-red from an acid bath. The hydrolysed product has practically the same dyeing properties. When this latter substance is treated with hydrochloric acid and nitrite, it yields a very stable bluish-red diazo compound, which, on combination with R salt, gives the same dyestuff as that obtained from (nitro-*p*-phenylene diamine + R salt) + R salt. As already mentioned, nitro-*p*-phenylenediamine (obtained by hydrolysing the diacetyl compound with concentrated hydrochloric acid) gives a diazo and not a tetrazo compound when treated with nitrous acid. This substance combines with R salt in an alkaline solution, forming greenish crystalline needles, which by reflected light appear blue. The compound dissolves easily in water; alkalis produce a crystalline precipitate, whilst acids change the shade to red. The colour is, however, too dull to be of use in wool-dyeing. The diazo compound has much the same properties as its isomeride, and can be employed for the production of symmetrical or mixed dyestuffs. For instance, nitro-*p*-phenylene diamine + 2 R salt dissolves in sodium carbonate solution with a blue colour, and dyes un mordanted cotton the same shade; but on washing and soaping, this turns violet, and hence is technically of no value, as the salt is dissociated also by a large quantity of water.—T. A. L.

*Rhamnazin.* A. G. Perkin and H. W. Martin. Proc. Chem. Soc. 1897, [181], 139.

RAMNAZIN was isolated from Persian berries by one of the authors and J. Geldard (this Journal, 1895, 565), and shown to be a quercetin dimethylether. The present

investigation was instituted to determine the position of the methoxyl groups. On methylation, it yielded quercetin-tetramethylether, and from this result and other experiments described in the paper, it evidently contains no methoxyl group in the phloroglucin nucleus in the ortho-position relatively to the carbonyl group. By fusion with alkali at 200°, rhamnazin yielded phloroglucin and protocatechuic acid, and digestion with boiling alcoholic potash gave vanillin, vanillic acid, and a non-crystalline phloroglucin derivative. Oxidised by air in alkaline solution, vanillic acid and a similar phloroglucin derivative were obtained. No free phloroglucin resulted from either of these decompositions. Taking into consideration that though the dyeing properties of rhamnazin are extremely feeble, it must still be considered a colouring matter, these results indicate that it has the constitution of a rhamnetin monomethylether.

*New Orgazo Compounds and Triphendioxazine Derivatives.* K. Anwers and H. Rohrig. Ber. 30, 988—998.

REQUIRING for cryoscopic investigations some *o*-hydroxyazo compounds containing para to the hydroxyl, a strongly negative group, such as NO<sub>2</sub>, CN, CO.R, ClHO, the authors have made use of Hamberger's reaction by combining nitrosobenzene with suitable *o*-amidophenols, and have obtained in this way a number of new derivatives. The *o*-amidophenols employed, were *o*-amido-*p*-nitrophenol, the methyl and ethyl ethers of *m*-amido-*p*-hydroxybenzoic acid, and *o*-amido-*p*-cyanophenol. The method consisted in dissolving equimolecular proportions of the reacting substances in the smallest quantity of glacial acetic acid at a medium temperature, and mixing the solutions, which as a rule turned dark and after a time deposited crystals either as long reddish needles or small plates. The product generally consisted of a mixture of two substances which could be separated by their solubility in acetic acid, the soluble portion being the hydroxyazo compound, whilst that insoluble in acetic acid was insoluble also in other usual solvents, and could only be dissolved by boiling nitrobenzene, aniline, or phenol, &c. These substances formed red or brownish-red plates, having a metallic appearance, and melting above 300° C. A characteristic property is the blue or bluish-violet colour they give with acids, and this is especially marked by dissolving them in sulphuric acid. These compounds are derivatives of triphendioxazine—

and, as a matter of fact, by the action of nitrosobenzene on *o*-amidophenol, a dyestuff has been obtained identical in all respects with the above. Hence nitrosobenzene not only condenses with *o*-amidophenol, but acts as an oxidiser. The proportion in which the two substances are formed depends upon the particular amidophenol. In the case of the ethers of *m*-amido-*p*-hydroxybenzoic acid, about 50 per cent. of the theoretical amount of crude or 40 per cent. of pure azo compound is obtained, whilst the yield of triphendioxazine dicarboxylic ether amounts to 25 per cent. of the theoretical. The yields in the case of *p*-nitro- and *p*-cyano-*o*-amidophenol were not so good, and in the latter case the azo compound was not obtained pure. Other new products were also obtained, and are described.—T. A. L.

*Amido Amidines.* C. Lauth. Comptes Rend. 124, [20], 1105—1106.

THE analogy existing between the amidines—

and the thiazoles—

led to the investigation as to whether the former, like the latter, were capable of giving dyestuffs. Hübner and Stoeber, by nitrating benzenyl-phenylene amidine—

and reducing the nitro product, obtained an amido base, but its constitution was uncertain, since it was not known into which nucleus the nitro group entered. The author has prepared an amido amidine of known constitution by heating 21.4 grms. of *o*-nitraniline with 32 grms. of *p*-nitrobenzoyl chloride to 100–105° C. for six hours. The product obtained, having the constitution—

crystallises from toluene in yellow laminae melting at 216° C. In order to reduce it, 30 grms. were heated with 300 c.c. of hydrochloric acid and 75 grms. of tin for one hour. The tin was then removed with sulphuretted hydrogen, and on evaporation of the filtrate, prisms of the hydrochloride of *p*-amidobenzyl-phenylene-amidine were obtained. The base—

is slightly soluble in boiling water, easily soluble in alcohol, and melts at 240° C. On repeating Hübner and Stoecker's experiments, a base was obtained melting at 281° C., and not at 245° C. as stated. The two bases differ, not only in their melting points, but also in their properties. The base (melting point 240° C.) crystallises in long prisms, its alcoholic solution shows a violet dichroism, and its hydrochloride—sparingly soluble in water—crystallises in prisms; whilst Hübner and Stoecker's base separates in spherical granules, its alcoholic solution shows a green dichroism, it is much less soluble in water than the isomeric base, and its hydrochloride—very soluble in water—crystallises in laminae. Both hydrochlorides diazotise easily, and on combination with various amines and phenols give azo dyestuffs which dye cotton directly, the shade varying from yellow, through red, to black, according to the nature of the dyestuff component. The shades, which are very similar from the two bases, are said to be fast to ordinary reagents, but not to light.—T. A. L.

*Tetramethyldiamidodiphenylcarbinol on Para- and Meta-Sulphanilic Acids, Products of the Action of. Suais.*  
Bull. Soc. Chim. 1897, 517–519.

On heating together in a litre of water, 46.2 grms. of sodium *p*-sulphanilate, 18 c.c. of hydrochloric acid, and 54 grms. of tetramethyldiamidodiphenylcarbinol on a water-bath for six hours to 80°–90° C., a number of products are obtained in practically equal quantities. 1. A yellow crystalline substance dyeing tannin-mordanted cotton yellow, similar to Auramine; it is decolorised by acids even in the cold. 2. A sulphonated leuco base converted by lead peroxide into a green dyestuff for wool, decolorised by alkalis. 3. Hexamethyltriimidodiphenylmethane (Crystal Violet). 4. A substance soluble in water, which does not yield a dyestuff on oxidation. With *m*-sulphanilic acid the following quantities were taken:—34 grms. of *m*-sulphanilic acid, 51 grms. of hydrol, 57 c.c. of hydrochloric acid, and 530 c.c. of water. After heating on a water-bath for 10–12 hours, the liquid contains several substances corresponding to those obtained from *p*-sulphanilic acid, with, however, certain differences. 1. The yellow substance only forms about 4–5 per cent of the mass. 2. The sulphonated leuco base is the principal product. On oxidation it yields a violet dyestuff, which is turned green by caustic soda. When diazotised, boiled with water, and then oxidised, it yields a green dyestuff, which is reddened by alkalis. If, however, the diazo compound be boiled with absolute alcohol and the product oxidised with lead peroxide, a dyestuff is produced which dyes wool bluish-green shades remarkably fast to caustic soda. According to its formation the substance is to be regarded as an *o*-sulphonated Malachite Green and the two following analogously constituted acids—

are being examined in a similar manner. The author regards the stability to alkalis as due to the *o*-position of the sulphonic acid group relative to the methane carbon—a constitution also possessed by the derivatives of the Patent Blue series.—T. A. L.

## PATENTS.

*Aromatic Nitro-Derivatives, The Manufacture and Production of New Products from.* J. Y. Johnson, London.  
From "The Badische Anilin and Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,955, July 6, 1896.

By the action of slightly fuming sulphuric acid on 1.1'- or 1.4'-dinitronaphthalene, products are obtained which, by further treatment in various ways, yield dyestuffs. For instance, about 10 kilos. of 1.1'-dinitronaphthalene are gradually added to about 50 kilos. of fuming sulphuric acid (12–23 per cent.  $\text{SO}_3$ ), the whole being stirred and the temperature maintained at 40°–50° C. until a sample is soluble in dilute caustic soda with a yellow colour. The melt is then poured into water and the precipitate filtered off. It may be purified by crystallisation from glacial acetic acid. The new product is not a dyestuff, but may be converted into one by treating it with fuming sulphuric acid (40 per cent.  $\text{SO}_3$ ), preferably in presence of sulphur. It then dyes chrome-mordanted wool brownish-yellow shades fast to light and milling. Brown to red dyestuffs are produced by the action of sulphuric acid of various strengths, with or without the addition of boracic acid or similar reagents. Dyestuffs are also obtained by treating the product with caustic soda or by nitrating it. On reducing the product it yields a base which can be employed in the manufacture of azo dyestuffs.—T. A. L.

*Colouring Matters [Cotton Blacks], Impts. in.* H. R. Vidal, Paris, France. Eng. Pat. 16,449, July 24, 1896.

The patentee finds that not only does sulphur react with disubstituted benzene and naphthalene derivatives, but that certain trisubstituted derivatives, such as diamidophenols and diamidonaphthols, react in a similar manner. Thus 3.2 kilos. of sulphur and 12.6 kilos. of 1.2.4-diamidophenol are heated [at 80°–120° C. for 6–8 hours, when a product is obtained which dissolves to a blue solution in alkaline sulphides and dyes cotton black. Sodium sulphide is added preferably to the melt, in order to dissolve the sulphur and diamidophenol. The diamidophenol may be replaced by the corresponding dinitrophenol or by dinitronaphthol, but in that case it is necessary to first reduce the dinitrophenol with sodium sulphide, and afterwards add sulphur. For instance, 1.840 kilo. of dinitrophenol (1.2.4 or 1.2.6, or a mixture of the two) is heated with 3 kilos. of sodium sulphide to 140° C. in a vessel provided with an agitator. After reduction, 350 grms. of sulphur are added. When the melt is finished, it is run out, cooled, and ground.

—T. A. L.

*Colouring Matters [Blues, Blacks], Production or Manufacture of New.* 1. Levinstein and Levinstein, Ltd., Manchester. Eng. Pat. 17,064, Aug. 1, 1896.

A FURTHER development of Eng. Pat. 2946 of 1896 (this Journal, 1897, 136). By heating with glacial acetic acid and anhydrous sodium acetate, the 1.4.2-diamidonaphthalene sulphonic acid there described, it is converted into an acetyl derivative having the formula—

which can be used for the preparation of dyestuffs. It is prepared by heating 1 kilo. of naphthalenediamine sulphonic acid with 3 kilos. of glacial acetic acid and 1 kilo. of anhydrous sodium acetate under a reflux condenser for about 12 hours. The reaction is complete when a sample is completely soluble in water. After distilling off the excess of acetic acid, the product remaining is sufficiently pure for technical purposes. It yields a sparingly soluble yellow diazo compound, which gives dyestuffs with amines and phenols. These, after saponification, can be again

diazotised and combined, yielding diazo dyestuffs; or, if the amine employed in the first combination be capable of further diazotisation after combination, trisazo dyestuffs can be obtained. The following is an example of the first method:—30·2 kilos. of amido-acetnaphthalide sulphonic acid are dissolved in 300 litres of water, cooled with ice, acidified with 24 kilos. of commercial hydrochloric acid, and diazotised with 7·2 kilos. of sodium nitrite in aqueous solution. The sparingly soluble yellow diazo compound separates, and, if combined with 35 kilos. of  $\beta$ -naphthol disulphonic acid R in an alkaline solution, a deep red dyestuff is formed, which may be salted out. In order to saponify it, the press cakes are boiled with 500 litres of 10 per cent. caustic soda until a sample on adding acetic acid gives a pure reddish-violet colour. An excess of hydrochloric acid is then added, and the whole is diazotised with 7·2 kilos. of sodium nitrite at a low temperature, and combined with 14·5 kilos. of  $\beta$ -naphthol in an alkaline solution. A dark blue dyestuff is thus produced, which gives greener and brighter shades on wool than the isomeric colour described in Eng. Pat. 2946 of 1896 (*loc. cit.*), and also possesses a greater affinity for vegetable fibres. If in this example the 35 kilos. of R salt be replaced by 24 kilos. of  $\gamma$ -amidonaphthol sulphonic acid, the dyestuff, after saponification, contains two diazotisable amido groups, and, moreover, dyes wool a deep violet black from an acid bath. In order to convert it into its tetrazo derivative, it is dissolved in 10 litres of water, cooled with ice, acidified with 70 kilos. of hydrochloric acid, and treated with an aqueous solution containing 14·4 kilos. of sodium nitrite. After stirring for about 12 hours the diazotisation is complete, and the whole is mixed with an aqueous solution of 25 kilos. of *m*-tolylene-diamine, the excess of hydrochloric acid being neutralised with sodium acetate. The mixture is then made alkaline and the dyestuff salted out, filter-pressed, and dried. It dyes animal and vegetable fibres a deep black. The base can be employed for other combinations also.—T. A. L.

*Amino-oxy-carbanil-carbonic Acid, and Azo Dyestuffs [Blue] therefrom, Fixing on Chrome Mordants: Manufacture of.* O. Imray, London. From G. H. Weiss, Charlottenburg, Berlin, Germany. Eng. Pat. 17,207, Aug. 4, 1896.

The specification refers to the production of dyestuffs from the base amido-oxy-carbanil carboxylic acid—

which is obtained by the action of phosgene on nitro-amido salicylic acid (m. pt. 220° C.) (from dinitro salicylic acid by partial reduction) and subsequent reduction of the condensation product. The nitro-amido salicylic acid is dissolved in water together with 4½ times the quantity of alkali theoretically necessary for its solution, and phosgene is passed in (below 35° C.) until a sample is no longer diazotisable, when hydrochloric acid is added to the melt to complete the precipitation. After purification by recrystallisation from hot water, the product forms needles melting at 263° C., easily soluble in water and alcohol, but insoluble in benzene. It is reduced by heating together 4·23 kilos. of the nitro body, 8 kilos. of tin, and about 16 kilos. of hydrochloric acid and the same quantity of water. The tin is removed by sulphuretted hydrogen or caustic soda, and the base is separated by sodium acetate or acetic acid. It forms white needles and melts at 252° C. It can be easily diazotised, and gives azo dyestuffs with the usual components, which produce very fast shades on chrome-mordanted wool; and better results still are obtained by a subsequent treatment with potassium bichromate. By combining the base with  $\alpha$ -naphthylamine or with 1·3'- or 1·2'-naphthylamine sulphonic acid, re-diazotising, and combining with naphthol, dihydroxynaphthalene or amidonaphthol mono- and disulphonic acids, dyestuffs are produced which give black shades on chrome-mordanted wool fast to soap, light, and fulling. The following example gives the quantities employed:—19·4 kilos. of the base are dissolved in 500

litres of water by means of 12 kilos. of 33 per cent. caustic soda lye and 7 kilos. of sodium nitrite are added. The whole is then cooled to 5° C. and run into 500 litres of water and 10 kilos. of hydrochloric acid (22° B.). A solution of 18 kilos. of  $\alpha$ -naphthylamine hydrochloride in 1,000 litres of water is then added, with constant agitation, to the diazo solution, and after adding sodium acetate, the reaction is complete in about six hours, when the amido-azo compound is filtered off. The press cakes are dissolved in 1,000 litres of water, together with the calculated amount of caustic soda lye mixed with 7 kilos. of sodium nitrite and slowly run at 15° C. into 50 kilos. of hydrochloric acid (22° B.) cooled with ice. The diazotisation is complete in about four hours, and the compound is then added to a solution kept alkaline with sodium carbonate, of 35 kilos. of  $\beta$ -naphthol disulphonic acid R. The dyestuff forms at once, and is separated by salting out and filter pressing. It dyes chrome-mordanted wool a deep and fast blue-black.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENTS.

*Vegetable Fibres, Improved Method of Extracting.* W. Warburton, Stockport. Eng. Pat. 13,815, June 23, 1896.

CINNA grass and similar fibres are extracted from the plants by placing the latter in galvanised wire baskets and subjecting them in an ordinary high-pressure kiler to the action of soap, soda, and petroleum under a steam pressure of 50—55 lb. per sq. in.—R. B. B.

*Horseshair, The Manufacture of a Substitute for.* H. W. Langbeck, Loughton. Eng. Pat. 29,168, Dec. 22, 1896.

COCOON fibres or "Mexican fibres" are boiled in an alkaline solution, well washed, and then dyed. When dry they are coated with a coloured spirit varnish and again dried. When the fibres are intended for upholstery this last drying is effected at 220°—240° F., but fibres to be woven are dried at the ordinary temperature.—R. B. B.

*Textile Fabrics, An Impt. in.* T. Zimmermann, Gnadendorf, Germany. Eng. Pat. 10,077, April 22, 1897.

THREADS are manufactured, composed of metal filaments and textile fibres twisted together, and these are woven or knitted into fabrics, being used either as warp or weft threads, or for both warp and weft.—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Turkey-Red Oil, Importance of, in Fixing Dyes.* P. Wolff. Chem. Rev. Fett- u. Harz-Ind. 4, [8], 103—106.

ALTHOUGH in some cases the action of the oil in brightening colours on the fibre appears to be due to a merely mechanical envelopment of the particles of dyestuff, in others (alizarin, for example) it would seem that the fatty acid enters into combination with the alumina and alizarin forming the colour lake, the result being in accord with the law that the brightness and fastness of a colour increase with the complexity of the molecule. Confirmation of this chemical action of the oil is afforded by the resistance towards discharging agents exhibited by Alizarin-red when oil has been used in the dyeing. Analogous results are obtained with the Diazo-red prepared from *p*-nitrodiazobenzene and  $\beta$ -naphthol, the use of oil being found to develop the brilliant blue shade characteristic of Turkey red.

Additional confirmation of the part played by the oil in the formation of a lake is afforded by the very fast brown produced by treating the *p*-Nitraniline red with cupric salts, warm, and the resistance of this red to stannous chloride when developed with oil.

It is also found that Turkey-red oil in conjunction with a cupric salt is essential in the production of a marine blue colour from tetrazodianisol, the resulting dye being said to be superior in fastness to all other blues; and, moreover, the shade obtained is in close relation with the oil used, ordinary Turkey-red oil giving reddish shades, ammonium ricinoleate

greener shades, and still greener and darker shades being produced by desulphurised oxyoleic acid. No action, however, is exerted by the oil on the developed colour—a circumstance pointing to a reaction between the oil and the naphthol, which is confirmed by an observation made in connection with cloth impregnated with sodium-naphthol. This was found to turn brown when exposed to air, and in this condition gave impure shades; but when the sodium naphthol was associated with Turkey-red oil or antimony oxide, or both, the oxidation of the first-named was retarded, especially in the latter case, when pure shades were obtained on development after four weeks' exposure to the air.

To judge of the quality of samples of Turkey-red oil, the dyer is recommended to have recourse to sample dyeings with *p*-Nitraniline Red, employing an oil of known quality for comparison.—C. S.

*Calico Printers' Blanketing, Floor-Cloth Printers' Blanketing, and the like: Impts. in the Method of and Means for Cleansing.* A. B. Wimpenny, Hayfield. Eng. Pat. 23,642, Oct. 24, 1896.

The blanket is brought into light contact with a revolving highly polished metal roller, which removes from it the greater part of the dirt and colouring matter. The colour, &c., is taken from the roller by one or more "doctors" and led into a trough. The blanket, after this treatment, is further cleansed in the ordinary washing machine by means of revolving or reciprocating brushes.—R. B. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Sulphur and Hydrogen, Conditions of Direct Combination of.* H. Pélabon. Comptes Rend. 1897, [13], 686.

M. HAUTEFEUILLE has shown that when sulphur and hydrogen are heated together at a temperature near to 440° in a closed vessel, they combine to form sulphuretted hydrogen, and also that sulphuretted hydrogen is dissociated at 440°. Furthermore, that at temperatures above 440° the combination is prevented by the inverse reaction (Comptes Rend. 64, 610).

Below 215° there is no combination.

Between 215° and 350° the combination is limited, but this is not owing to any inverse reaction. The author has already shown that when sulphur and hydrogen are heated together, the quantity of sulphuretted hydrogen produced increases as the mass of sulphur employed is more considerable, owing to the fact that molten sulphur is capable of absorbing H<sub>2</sub>S and gives it off again on solidifying (H. Pélabon, this Journal, 1897, 142).

The direct combination is quicker in proportion to the elevation of temperature.

The maximum quantity of H<sub>2</sub>S produced (that of the sulphur employed being the same) increases very rapidly as the temperature employed is higher. Thus, taking in each case 0.02 grm. of sulphur, when the temperature was 220°, only 2.10 per cent. of the hydrogen present was converted into H<sub>2</sub>S, even after 624 hours of heating; while, with a temperature of 350°, 97 per cent. was so converted on 27 hours' heating.

When, however, these same experiments were made, using 50 times as much sulphur, very different results were obtained, owing to the absorption of H<sub>2</sub>S by molten sulphur already referred to.

Beyond 440° the results are the same, whether a mixture of sulphur and hydrogen or the gas H<sub>2</sub>S alone be employed. If, instead of pure H<sub>2</sub>, a mixture of H<sub>2</sub> and N be used, the quantity of H<sub>2</sub>S produced at any given temperature, is lessened, but, other conditions remaining the same, the difference is less as the temperature is increased.—J. H. C.

*Aluminium Chloride, The Preparation of.* R. Escales. Ber. 1897, [10], 1314—1317.

In the preparation of aluminium chloride by the action of hydrochloric acid gas on aluminium, it is not necessary to apply heat during the whole process. If the metal be heated at the commencement, the heat generated by the reaction is sufficient for its completion. A bell-jar with two tubulures is placed air-tight on a glass plate; on this plate is a glass dish, which should be as large as possible; above the dish, supported on a glass tripod, is an asbestos sheet covered with 20 grms. of aluminium filings. Through the lower tubulure, hydrochloric acid gas is introduced; when most of the air is expelled, 0.5—1 grm. of heated aluminium is thrown in through the upper tubulure. This is conveniently heated in a crucible, and must be as hot as possible; if the reaction does not commence, a second quantity is added. The aluminium chloride produced sublimes on to the sides of the bell-jar. If the stream of acid be carefully regulated, very little chloride issues from the tubulure; to prevent any loss, this may be fitted with a tube.—A. C. W.

*Metastannyl Chloride.* R. Engel. Comptes Rend. 1897, 124, 765—768.

It is well known that the reactions of stannic chloride vary according to the nature of the solution used, a freshly prepared aqueous solution of the anhydrous chloride not giving the same reactions as a similar solution when old, or as one prepared by the action of hydrochloric acid on metastannic acid ("β-chloride"). Regarding the distinctive reactions and true nature of the β-chloride, different observers are, however, by no means in agreement. Schützenberger considers it to be a chlorhydrin of metastannic acid. This view the author confirms, but at the same time concludes, from his observations, that there exist two distinct β-chlorides, differing in properties, and corresponding to two distinct metastannic acids. One of these chlorides is obtained when metastannic acid (prepared by the oxidation, at a comparatively low temperature, of tin by nitric acid) is treated with one-fourth of its weight of hydrochloric acid, and the resulting solution, after slight dilution, precipitated with an equal volume of hydrochloric acid. The precipitate, when dried *in vacuo*, forms translucent masses having the composition expressed by the formula Sn<sub>2</sub>O<sub>3</sub>Cl<sub>2</sub>.4H<sub>2</sub>O (*Metastannyl chloride*). The salt is deliquescent in moist air, and is very soluble in water and absolute alcohol. The aqueous solution remains bright when diluted, providing a few drops of hydrochloric acid be added. But if largely diluted, the acid being omitted, a white gelatinous precipitate of metastannic acid (Sn<sub>2</sub>O<sub>3</sub>.11H<sub>2</sub>O.4H<sub>2</sub>O) is obtained, from which, when dried, the chloride may readily be regenerated.

Stannic chloride, in dilute solution, is gradually converted into the meta-chloride in accordance with the equation 5SnCl<sub>4</sub> + 9H<sub>2</sub>O = Sn<sub>2</sub>O<sub>3</sub>Cl<sub>2</sub> + 18HCl.

An acidulated solution of metastannyl chloride is not precipitated by dilute sulphuric acid. In a note to follow, the author will describe the properties and mode of preparation of another chloride, corresponding to a second metastannic acid, the solution of which does yield a precipitate on addition of sulphuric acid.—H. T. P.

*Magnesium Sulphate, An Adulteration of.* P. A. Lamanna. Boll. Chim. Farm. 36, 198; Chem. Central-Bl. 1897, 1100.

*Electrolytic Decomposition of Liquids [Alkali Chlorides, &c.], Impts. in or connected with Apparatus for the.* G. and G. W. Bell, Liverpool. Eng. Pat. 11,133, May 22, 1896.

See under XI. A., page 617.

*Water-Glass, Impts. in the Manufacture and Production of, with Valuable By-Products [Hydrochloric Acid, Chlorine, Nitric Acid] of the said Manufacture.* H. Propfe, Mannheim, Germany. Eng. Pat. 14,953, July 6, 1896.

WHEN it is desired to obtain hydrochloric acid as a by-product, a mixture of 100 parts of sand, 60 parts of sodium chloride, and 4 parts of charcoal is heated, and 60 parts of sulphuric acid are admitted. The HCl is evolved at 200° C. The residual mixture is then transferred to the melting furnace and fused to water-glass. Saturated brine may replace the salt; sawdust or peat, the charcoal; and sodium bisulphate, the sulphuric acid.

To obtain chlorine, a mixture of sand, rock salt, and saltpetre is treated with sulphuric acid, and charcoal is added to the residual mixture before fusing it to water-glass. Nitric acid is obtained by similarly treating a mixture of sand and saltpetre, charcoal being, as before, added to the residue before fusion. To obtain nitrobenzene or similar nitro compounds, by a corresponding method, benzene is added to a mixture of sand and saltpetre, and then, slowly, sulphuric acid. The use of the spent sulphuric acid of the mineral oil industry for obtaining hydrochloric acid as a by-product is claimed; and in this case the impurities present serve to replace the reducing agent otherwise required.—E. S.

*Oxalic Acid, Improved Process for Producing.* G. F. Zacher, Hamburg, Germany. Eng. Pat. 2308, Jan. 28, 1897.

SAWDUST or other cellulose material is placed in a steam-jacketed vessel connected with an air-pump. After exhaustion of air, the temperature is slowly raised to about 70° C., to deprive the sawdust of moisture and air. Hot alkali lye is then admitted, and stirring is maintained, and the vacuum kept constant until a temperature approaching 180° (but not exceeding that) is reached. Near the end of the process, either an oxidiser, such as sodium peroxide or hydrogen peroxide, is added; or air enriched with oxygen is slowly sucked in. The finished product is dissolved in water in the same vessel, and the solution is forced into an open stirring cylinder, in which it is thinned and treated with lime. The calcium oxalate obtained, practically free from carbonate, is decomposed by sulphuric acid; and it is stated that "a good white oxalic acid is produced by this improved process with only one cry-tallisation."—E. S.

*Ammoniacal Liquor, A Process for Removing Carbonic Acid and Hydrogen Sulphide from.* A. Feldmann, Bremen, Germany. Eng. Pat. 10,501, April 27, 1897.

GAS LIQUOR is heated in distilling columns to from 94° to 97° C., at which temperature "a simultaneous and sufficiently complete removal of carbonic acid and hydrogen sulphide will be effected." It is supposed that at the stated temperature ammonium carbonate is dissociated, and that the carbonic acid set free, decomposes ammonium sulphide, liberating hydrogen sulphide. A column apparatus suitable for the conduct of the process is shown.—E. S.

*Acetates of Lead, Copper, and the like; Process and Apparatus for the Production of the.* A. Schmidt, Cassel, Germany. Eng. Pat. 7192, March 19, 1897.

THE apparatus employed to produce neutral lead acetate consists of a pair of closed iron cylinders, lined internally with acid-resisting materials, connected at the lower part by tubes worked by an intermediate pump, and above by a valved arched pipe. Each cylinder has a steam-heating compartment at the bottom, a man-hole at top, and other accessories. The cylinders are half-filled with shot or small pieces of lead, and the second of them is charged until about three-fourths full with dilute acetic acid, and heat is applied. When the upper space of the cylinder is full of the acid vapour, the man-hole is closed, and the acid is pumped into the first cylinder, while oxygen under pressure is admitted. After the oxygen has acted upon the moist lead surfaces for about half an hour, the acid is pumped

back, and the oxygen passes into the other vessel, where it acts similarly; and the process is continued, at a temperature of from 50 to 60° C., as long as necessary. After withdrawing the solution of lead acetate, fresh acid is added and the process repeated. Neutral copper acetate is similarly obtained, copper being substituted for lead.

To obtain subacetate of copper, a single cylindrical vessel, having a perforated false bottom above the steam-heating compartment, is used. Thin copper plates, separated by wooden laths, are placed upon the false bottom, below which acetic acid is introduced, the vapour of which, on applying heat, displaces air; oxygen is then forced in, to act jointly with the acetic acid vapour on the copper surfaces. By regulating the proportions of the oxygen and acid, a salt of any required basicity is produced.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

*Pottery, Studies in the Art of; especially the Influence of the Furnace Atmosphere on the Colours given by Metallic Oxides.* M. E. Damour. Bull. Soc. d'Encouragement, 1897, 322—325.

THE author finds (1) that the coloration varies in a regular and continuous manner with the composition of the furnace atmosphere: excellent plates are given showing the colours obtained in the experiments; (2) that the tints obtained are constant with a constant atmosphere; (3) that with a naked fire the coloration is uncertain and unequal even when the greatest care is exercised.

The opinion is expressed that for fine porcelain the attempt should be made to introduce in commercial practice a muffle furnace heating to 1,300° C. The question of heating is still the key of all important progress in the potter's art, and an exact knowledge and control of temperature are subjects demanding the closest attention.

—V. C.

*Glass, Colouring by Direct Penetration of Metals or Metallic Salts.* L. Lemal. Comptes Rend. 124, [20], 1097—1099.

THE author finds that by applying a salt of silver to the surface of glass at a temperature of 500° to 550° C., the glass becomes coloured pale to dark orange-yellow according to its composition, the former shade being produced in ordinary glass and the latter in glass prepared from:—sand 100 parts, lime 10, sodium chloride 20, sodium sulphate 34, sodium carbonate 5, arsenic 0.5, alumina 3, and carbon 1.5 parts, the colouring agent in both cases being a mixture of 10 grms. of silver sulphide and 100 grms. of red ochre.

The amount of silver salt required is very small, a 1 per mil. solution of silver nitrate sufficing to reproduce in dark yellow the design of a piece of lace dipped therein, and, after immersion in potassium sulphide, applied to the heated glass. The same result was obtained from a collodion photographic print.

The penetration effected by the silver salt increases with the strength of the solution and the time of exposure to heat. After heating for 5 minutes the glass was penetrated to a depth of 0.17 mm., and, after another hour's heating, to 0.32 mm.; and by renewing the colouring composition at intervals of 6 hours, a sheet of glass 1.57 mm. thick was found completely permeated after heating for 18 hours.

The coloured glass is dichroic, reflecting a phosphorescent tinge ranging from yellowish-green to bluish-violet—a property intensified by the addition of powdered copper (reduced from copper sulphate by zinc). In the case of glass coloured red by means of  $\text{Cu}_2\text{O}$ , a photographic reproduction by the new process, gave the dichroic image by reflected light, but it was invisible by transmitted light, the colour being masked by the copper red.

Coloured glasses, except those coloured with manganese oxide, transmit the imprint produced by the new process, and analogous results to those in the case of silver are obtained by using gold, copper, or iron.

In a note to the paper, A. Gantier states that he has already, in conjunction with Helier, observed a penetration of glass by metallic silver in vessels containing hydrogen

(or oxy-hydrogen) gas when exposed for several hours to a temperature of about 450° C. The silver disappeared, leaving the glass opaque, but the latter afterwards recovered its transparency.—C. S.

### PATENTS.

*Glass-Etching Plates for Use in Reproducing Designs on Stone, Zinc, Copper, Brass, and the like: Method of Producing.* T. Löhler, Mannheim. Eng. Pat. 9901, May 9, 1896.

A METHOD for producing a non-transparent white coating upon glass plates for etching, in which the plate is first covered with a layer of "collodion and iodine," then treated with a solution of silver nitrate, next with an aqueous solution of green vitriol containing sulphuric acid and alcohol, and finally with a solution of mercury and albumin. The plates can be removed by treating with "the dry vapours of volatile chemicals."—V. C.

*Glass, Impts. in the Manufacture of Sheets, Cylinders, and other Forms of.* P. T. Sievert, Dresden. Eng. Pat. 17,391, Aug. 6, 1896.

THE inventor claims the employment of a glass-melting furnace with slits of the required shape for the molten glass to pass through by gravity, in order to be drawn into a form corresponding to the slits, in combination with an arrangement of furnace for heating the glass at its exit.—V. C.

*Glass-melting Furnaces or Troughs, Impts. in or connected with the Construction of.* W. P. Thompson, Liverpool. From M. Mühlig, Teplitz, Bohemia. Eng. Pat. 2315, Jan. 28, 1897.

THE inventor claims glass-melting furnaces constructed of an improved brick, "which is provided with recesses or

bulgings, with the object of producing a more intense cooling of the walls of the furnaces or troughs and the joints of the bricks."—V. C.

*Ceramic Masses, Improved Process for Producing.* C. C. Schirm and O. Lessing, Berlin. Eng. Pat. 4539, Feb. 19, 1897.

THE process consists in mixing fired, powdered materials (porcelain, earthenware, &c.), plaster of Paris, and flux, firing the mixture, and subsequently saturating it in a water-glass solution.—V. C.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Puzzolana and its Practical Use.* J. Zervas. School of Mines Quarterly. 18, [3], 226.

As its name implies, puzzolana was formerly found principally at Puzzuoli, in the neighbourhood of Naples, though at the present time a similar material is obtained from many other places, as from the valley of the Rhine (where it is known as tuffstone, or in the powdered condition as trass), the Azores, Schemnitz, Auvergne, &c. The Italian puzzolana is mostly obtained from shallow open pits, but large deposits are also found. Besides being indifferently manufactured, the material itself is inferior to the products from the Rhine and the Azores. French engineers use less of it than they formerly did in their marine constructions, and Dutch engineers employ "trass," which is selected and manufactured with greater care. Both puzzolana and trass are the products of former volcanic eruptions, and, though different in appearance, are substantially the same in chemical composition, as will be seen from the following table of analyses:—

Trass (Germany).							Puzzolana.

All that is needed to make a good hydraulic mortar is lime, and this is added with the sand. Probably equal parts of puzzolana (or trass), lime, and sand give the best results. The proportions used in the Kiel harbour works were:—

Trass .....	3 parts by volume.
Fat-lime paste .....	2 " "
Sand .....	7 " "

In Holland the following are the standard formulæ for hydraulic works:—

	Trass.	Shell-lime Paste.	Sand.	Stones.
Strong trass mortar.....	1 vol.	1 vol.	..	..
Second quality .....	2 vols.	4 vols.	1 vol.	..
Third quality .....	2 vols.	6 vols.	3 vols.	..
Concrete .....	1 vol.	1 vol.	..	1½ to 1 vol.

As trass and puzzolana commence to harden only after the addition of the lime, they can be stored, even in damp places, without deterioration; and this renders it possible to

export them without the risk incurred in shipping Portland cement, whilst it also enables the engineer to make better arrangements with regard to purchase and storage. If the lime used be perfectly slaked, mortars made with puzzolana or trass do not suffer the expansion or contraction so commonly observed with cement. Mixed with 20 per cent. of water, puzzolana mortars composed of 1 volume each of puzzolana, lime, and sand, 28 days old, break at more than 200 lb. per sq. in.

To test impermeability to water, a circular conical disc of 20 cm. surface at the smaller face and 15 mm. thick, is made of standard mortar and hardened in water. By means of a rubber ring, the disc is tightly fitted into a cylinder, and while water is filled into the cylinder above the disc, the air is exhausted from below. After 24 hours, the percolated water is weighed. Comparative experiments made with puzzolana and trass, and with slow-setting cement, show results greatly in favour of the former, and this important quality is fully recognised by Dutch and German engineers in the construction of sluices and basins.

Experiments made to test the adhesive strength of mortar to stone in concrete, showed that, unlike cement, puzzolana and trass mostly yield a higher strength by the

addition of the stones. The same experiments also showed that a larger addition of lime should be made to puzzolana or trass when made into concrete than when used without stones.

In order to test the adhesive strength of separate layers of mortar, experiments were carried out as follows:—Specimens, prepared in the same way as for testing tensile strength, were made and immersed in water to harden. After lying in water for certain definite times, some of the specimens were taken out and divided into halves, the remainder being allowed to remain in the water, to be used later on for testing for tensile strength. Each of the halves was placed again in a mould, the empty half of the mould filled up with fresh mortar, carefully pressed to the old half specimen, and the whole re-immersed in water. The results obtained are shown in the following tables:—

TABLE I.

Mixture.	Medium Temperature of Water.	Tensile Strength after 28 Days. Kilos, per Square Centimetre.	
		Regular Specimens.	Specimens joined after 24 Hours.
1 trass, 1½ fat-lime paste, 3 sand, without water.	19½	15.00	12.00
Cement, standard mixture ..	19½	11.25	6.25

TABLE II.

Mixture.	Temperature.	Regular Specimens.	Joined after 36 hours.
	° C.		
Trass. The same as in Table I.	15½	13.25	9.25
1 trass, 1 fat-lime paste, 1 sand, and 5 per cent. of water.	15	14.50	11.00
Cement, standard mixture ..	15	9.50	4.00

Puzzolana or trass mortar sets harder in sea-water than in soft water. Taking the tensile strength of the mortar hardened in soft water at 100, the same hardened in sea-water showed the following results:—

Trass.	Fat-lime Paste.	Sand.	After 28 Days' Hardening.
2 parts by weight 1 part 1 part by volume	1 part by weight " " volume	1 part by weight 2 parts by volume	111 168 132

Trass has been used in the construction of most of the bridges over the Rhine, Weser, and Elbe, in the maritime works of the German Government, and in Holland and Belgium, 60,000 tons having been used in the construction of the Antwerp docks alone.—H. H. B. S.

*Cement Water Pipes for Dye-works.* Leipziger Färber-u. Zeugdr.-Zeit. 46, [6], 257.

WATER pipes made of hydraulic cement will stand a high pressure, and buried in moist ground are indestructible. They are made locally, where wanted, as follows:—On the well-prepared foundation a gutter is made by means of two boards. In the centre of this, lengthwise, a smooth sheet-iron pipe, of the thickness of the desired bore, is laid, and the prepared cement, consisting of two parts of hydraulic cement to one part of pure sand mixed with water, is poured over it. After about 15 minutes, when the cement has partly set, the iron tube is carefully turned round and pulled out, leaving the end only in the casting, and the previous operation is repeated. In this wise a pipe of any length can be made in one piece. Pipes of larger diameter may be

constructed in a similar manner, by using for the core a tube consisting of wooden staves, so constructed that one of them can be pulled out when the cement is sufficiently hardened, whereupon the others can be easily removed.

—I. S.

## PATENTS.

*Silica Bricks or other Highly Refractory Bricks, Impts. in the Manufacture of.* J. Dixon, Oughtibridge, and A. Reynolds, Bolsover Hill, near Sheffield. Eng. Pat. 11,682, May 29, 1896.

To suitable siliceous material is added "half-stuff," cellulose, or other like fibrous material, which acts as a binding agent during the process of moulding.—V. C.

*Artificial Stone, Marble, and the like; An Improved Manufacture of.* W. Owen, Brixton. Eng. Pat. 12,368, June 5, 1896.

A METHOD of manufacturing artificial stone and the like, in which the component parts are subjected to pressure under water free from air. A cylinder of special construction, which is described and figured in the specification, is also claimed.—V. C.

*Paving Blocks, Tiles, and the like; Impts. in the Manufacture of.* W. S. Wilkinson, Baltimore, U.S.A. Eng. Pat. 5439, March 1, 1897.

IN the manufacture of compressed paving blocks, &c., the inventor claims a preparatory treatment of the asphalt, which consists in pulverising it and then macerating and agitating it in water. The ingredients besides the asphalt, are non-calcareous hard-stone debris and powdered limestone.—V. C.

*Fillings for Coating Wood before Painting the same, Impts. in.* Ph. Phillips, Baku, Colony of Victoria. Eng. Pat. 8686, April 5, 1887.

"Tun white lead," ground pumice stone, and varnish are mixed, either alone or with powdered asbestos. Pyrites are added when more durability is required.

The proportion used for an ordinary coating is 8 lb. of white lead, 4 oz. of pumice stone, 8 oz. of asbestos, and 1¼—1½ pints of varnish.—E. A.

## X.—METALLURGY.

*Dredge-Work in the Siberian Placers.* E. D. Levat. Eng. and Mining J. 1897, 63, 541.

THE author, in his report on the gold-fields of the Trans-Baikal, describes the use of the dredge for working the second level of placers where the subsoil is yielding and marshy. He describes the bucket dredge used by the Verkhne-Zeya Company, which, owing to its large weight and the difficulty of moving it from place to place as desired, had to be mounted on a barge or pontoon, and floated in an artificial basin, filled with water from a stream flowing through the placer. The bedrock, on and in the cavities of which, nuggets are generally found, is worked over by hand as it is uncovered by the dredge. The gravel brought up by the buckets is deposited in a sluice carried on the dredge-boat; the water for the sluice, which is provided with riffles at the bottom, is furnished by a centrifugal pump. The tailings from the sluice are discharged into a wooden float, which, when full, is hauled to the side of the excavation and there discharged. The chief defect is the shortness of the sluice, which prevents the complete washing of the gravel. The author suggests the use of a Z-shaped sluice, with one or two under-currents.—A. S.

*Furnace, The Bolthoff-Wetley Improved Roasting.* Eng. and Mining J. 1897, 63, 545.

THIS is a modification of the Wetley multiple-deck calcining furnace, arranged for the desulphurising of ores for chlorination and cyanide mills where a "dead roast" is desirable. The furnace is of rectangular form, and being supported by the same means on both sides, is not liable to injury from expansion and contraction. The design is such that no iron-work is exposed to the fire except the rabbles, which are

constructed of heavy pipe, to which steel ploughs are clamped, and are supported at both ends by carriages and driven by wire rope and sprocket wheels. The carriage is so constructed that the rabble pipe and ploughs can be lifted out and replaced without disturbing the connection between the carriage and the rope. Half of the ploughs on each rabble are set at one angle and half at an opposite angle, thus overcoming all end thrust. The ore is charged into the furnace at the driving end, and after travelling the full length of the roasting hearth is dropped to the cooling hearth and carried back to the charging end, thus allowing the ore the same length of time to cool that was required to roast it. In order to facilitate the cooling of the ore and ensure its temperature being sufficiently low to prevent injury to the conveyors and elevators, water pipes are laid the full length of this hearth, flush with the top: the amount of water necessary for the cooling of the ore can be regulated by the discharge from these pipes. The pipes are laid loose in grooves between the brick in such a manner that they can expand and contract without injury to the hearth or themselves. A valve is provided for shutting off the stream of ore from the feeder while the rabble is passing under it. All the ironwork of the furnace is exposed to the atmosphere, and is thus less liable to injury from the corroding action of the fumes than where the ironwork is enclosed or passes through the brickwork. It is claimed that this furnace is cheaper and requires less space than other types of furnaces.

—A. S.

*Zinc-Box Precipitate, The Treatment of.* T. H. Leggett. Eng. and Mining J. 1897, 63, 541. From the J. Inst. of Mining and Met., London.

THE author describes a process for the cleaning up and drying of the zinc-box precipitate from the cyanide process. The slime sediment from the zinc extractor boxes is placed in a wooden tank, into which the zinc shavings are also washed through a coarse screen. The cyanide solution brought into the tank with the slimes and shavings is then pumped out by means of an india-rubber hose pipe attached to the pump-suction. It is forced through a press, leaving the slimes at the bottom of the tank in the form of a thick mud. Concentrated sulphuric acid is then poured on, a bucketful at a time, until all the zinc is dissolved, a hood being lowered on to the tank for the purpose of leading the fumes outside the building. Boiling water is now run on to the slimes, which are kept agitated, until the tank is filled, when the hot slimy solution is drawn off by the pump, and forced through a filter press; the solution is kept stirred all the time, and more hot water is run in as required until the tub is empty. The slime cakes in the filter press are further washed by hot water until all acidity and zinc sulphate are removed, after which air is pumped through and the cakes finally taken out and dried in a closed muffle without stirring, so that no dust is made.

The following results were obtained by this method at the Treasury Mine, Transvaal. Weight of dried slimes, 108 lb. av. = 1,575 oz. troy; sulphuric acid used, 234 lb. av.; flux used—borax 5 parts, soda 3 parts, precipitate 10 parts; slag produced, 48 lb.; gold produced, 446.81 oz. fine; silver, 55 oz. fine. The bullion produced assayed 750.3 fine gold and 92.9 fine silver, or 843.2 total per 1,000. The solutions escaping from the filter press assayed 8 c. per ton in gold; and 400 gals. of hot water per 1,000 oz. of precipitate were used for washing. The total losses by this method are under 0.1 per cent., while much less and far cleaner slag is produced than by the nitre method, together with a higher grade of bullion.—A. S.

*Metallic Sulphides, Formation of, by Mechanical Means.* L. Franck. Bull. Soc. Chim. 1897, 504—506.

A NUMBER of instances are quoted in which small quantities of metallic sulphides are obtained by rubbing together, between paper, flowers of sulphur with certain metals in powder. When aluminium powder is rubbed together with flowers of sulphur, sulphuretted hydrogen is given off, and a similar reaction occurs with magnesium. On rubbing a silver plate or coin with flowers of sulphur, a yellow and then a black colour is produced, due to the formation of

silver sulphide. On continuing the friction, the surface becomes uneven, and excrescences are formed, which, on removal, are found to contain silver sulphide. A gold coin shows a similar reaction, whilst with copper the effect is even more distinct. A freshly-cut surface of lead, when rubbed with flowers of sulphur, gradually turns black from the formation of lead sulphide.—T. A. L.

*Metallic Sulphides [Cu, Bi, Ag, Sn, Ni, and Co], Influence of a High Temperature on.* A. Mourlot. Comptes Rend. 1897, 124, 768—771.

THE author has submitted various sulphides—mostly prepared artificially—to the high temperature of an electric tube furnace, as used by Moissan. The conclusions are as follows:—

1. Copper and bismuth sulphides are completely desulphurised—in the case of copper, with distinctly greater difficulty than with bismuth.
2. Silver sulphide is similarly decomposed, but the reduced metal obstinately retains traces of sulphur.
3. Cobalt and nickel sulphides are reduced to relatively stable CoS and NiS respectively, which at the maximum temperature of the furnace are further desulphurised, but not completely, a trace of sulphur being obstinately retained.
4. Stannous sulphide is not decomposed at the highest temperatures attainable, but is partly volatilised, partly converted into a crystalline mass of SnS, and must therefore be classed along with zinc, cadmium, and aluminium sulphides, which are stable at high temperatures.—H. T. P.

*Nickel Steel, Metrological Properties of.* E. Guillaume. Comptes Rend. 1897, 124, 752—755.

THE author has previously referred (Comptes Rend. 1897, 124, 176) to the very small expansibility by heat of certain alloys of nickel and steel, and he pointed out the value of such metal for the construction of scientific apparatus, &c. The resistance of nickel steel to corrosion by moisture increases with the percentage of nickel present, and is already sufficiently marked in case of the alloy possessing minimum dilatability (containing about 36 per cent. Ni). Polished bars of this metal retain their lustre for months in a damp atmosphere, and even for a considerable period when submerged in water. Unpolished surfaces, however, rust in the course of a few days; and in any case, the attack, when once initiated, proceeds rapidly. All the alloys are very readily attacked by dilute hydrochloric acid.

As regards density and elastic modulus of nickel steel, it appears, roughly speaking, that minimum dilatability is accompanied by low density (as compared with the calculated mean density) and low modulus, and *vice versa*. (The most expansible alloy contains about 24 per cent. Ni). In order to determine the effect of annealing, test bars were repeatedly heated, and their length measured at intervals when cool. At 100° C. the alloys containing less than 25 per cent. of nickel contract permanently, whilst those richer in nickel expand. The absolute amount of expansion is greater at low than at high temperatures; but the rapidity with which the change takes place is greater, and the time required for a fixed and definite length to be attained, shorter at high temperatures. In confirmation, the curious fact is cited of a bar, which, when annealed at a given temperature, again expands when subsequently heated to a lower temperature, or contracts at a higher temperature. As regards the least dilatable alloy, a condition of equilibrium is arrived at in 20 hours at 150° C., 100 hours at 100° C., 300 hours at 60° C., 700 hours at 40° C., and in about two months at the ordinary temperature.—H. T. P.

*Silver-Copper Group of Alloys.* F. Osmond. Comptes Rend. 124, [20], 1094—1097.

FROM the curves of fusibility obtained by Heycock and Neville (Trans. Roy. Soc. 189, 25), it appears that the silver-copper alloys are merely mixtures of the two metals, and the existence of Levor's alloy, Ag<sub>3</sub>Cu, as a definite compound is thus called in question. By subjecting this alloy to microscopic examination the author finds that the metals are distinctly separate, being recognisable by their colour, especially if the oxide colours of the copper be developed by heating; and that the structure of the alloy

resembles that of perlite, the copper being distributed in curved lamellæ, like the  $\text{Fe}_3\text{C}$  in iron, and producing a similar iridescence when slightly oxidised and viewed by oblique light. A power of 1,000 diameters is necessary to detect the grains of primary consolidation, which are enveloped in grains of coarser structure of the secondary order. When the cooling of the alloy is hastened, the lamellæ are still rendered visible by the iridescence, but their structure is not easy to distinguish, even under the highest powers. The results obtained, confirm the inferences drawn from the plotted curves of fusibility, and disprove the existence of  $\text{Ag}_2\text{Cu}$  as a definite compound. —C. S.

*Alloys, Metallic: Constitution of.* G. Charpy. *Comptes Rend.* 1897, 124, 957—958.

*Eutectic Alloys.*—These alloys have often been considered chemical compounds because they are homogeneous and solidify at a constant temperature; but the microscope shows that they consist of crystalline lamellæ of two constituents juxtaposed, and so minute that the structure is evident only under great magnification. The minuteness of the structure explains the apparent homogeneity and the conchoidal fracture. These alloys have the constitution of euhydrides; they are not definite compounds, but resemble the mixtures of liquids distilling at definite temperatures studied by Berthelot. The pearlite in steel shows all the characteristics of such an eutectic mixture, and this is in opposition to Arnold's contention that the pearlite is a definite alloy of carbon and iron, corresponding to  $\text{Fe}_2\text{C}$ .

*Definite Compounds.*—The existence of definite compounds of metals has been denied, and few besides  $\text{Cu}_3\text{Sn}$  and  $\text{Cu}_3\text{Sb}$  have been completely investigated. Micro-metallurgy shows the existence of these compounds. Thus,  $\text{Cu}_3\text{Sn}$  is seen in alloys containing more than 5 per cent. Cu in the form of white, very hard crystals forming six-branched stars (like snow crystals), increasing in number as the proportion of copper is gradually approximated to that contained in  $\text{Cu}_3\text{Sn}$  itself.  $\text{Cu}_3\text{Sb}$  is shown in the same way by the presence of hard violet-coloured crystalline forms. Microscopy also shows the existence of other definite compounds not yet isolated, and is of great use when the physical properties of the alloy give no clear indications, probably owing to phenomena connected with isomorphism. It has given evidence of the existence of the following compounds, which, however, remain to be isolated:—Of antimony and tin, with about 50 per cent. of Sn, and isomorphous with Sb; of antimony and silver, containing about 20 per cent. of Sb, isomorphous with Ag; of tin and silver, with 30 per cent. of Sn, isomorphous with Ag. The first-named of these gives beautiful crystals, with clear outline, in alloys rich in tin. In micro-metallurgy the form of the constituents of an alloy gives only an approximate indication, and better information is yielded by the colour, hardness, and by their behaviour towards various reagents.

Two types of structure are indicated by microscopic examination. In the first, crystals of a pure substance (element or compound) are enveloped in another substance, which is usually an eutectic mixture formed from two finely divided materials, of which one is identical with the substance of the crystals. In the second, isomorphous mixtures give a single type of crystals, which occupy the whole space, the composition and properties varying uniformly in each crystal. This type is of frequent occurrence; for, although but few metals are able to form isomorphous mixtures, there are many examples of definite compounds capable of forming such mixture with one or other of the constituent metals. —W. G. M.

*Phosphor Bronze, The Manufacture of.* M. H. Wickhorst. *J. Amer. Chem. Soc.* 1897, 19, [5], 393—395.

PHOSPHOR BRONZE is bronze containing a small amount (from a few hundredths to over 1 per cent.) of phosphorus, which may be added in substance as phosphorus, or in the form of a high phosphorus alloy. The latter method is the one described, and the high phosphorus alloy or "hardener" is made in the following manner:—90 lb. of copper are melted in a crucible under charcoal, 11 lb. of tin added, and the mixture heated.

The phosphorus to be added to the metal is weighed out in the following manner:—A stone jar half full of dilute copper sulphate solution is weighed, and phosphorus, in sticks about 4 ins. long, is added until the weight is increased by 7 lb. At the end of about half an hour the phosphorus is covered with a coating of metallic copper, which prevents ignition when it is dried and exposed to the air. The phosphorus is dried on blotting paper, placed on wire netting supported from ledges along the inside of a shallow, square, galvanised iron pan, containing about 2 ins. of water; the pan is provided with a lid, which may be put down in case of fire.

The crucible containing the molten metal is placed on the floor, and a cup-shaped instrument, called a retort or phosphoriser and fitted with a long handle, is held just over the brim. Two or three pieces of the prepared phosphorus are then placed in the retort and the latter immediately plunged into the metal before the phosphorus can fall or flow out. This operation is repeated, and after the 7 lb. of phosphorus have been thus added, the mixture is poured into thin slabs about 1 in. by 3 ins. by 1 in.

The phosphor bronze is prepared by melting the copper under charcoal, adding the tin and lead, and then enough "hardener" to obtain a sufficient amount of phosphorus. —A. S.

*Metals, Deformation of, under Strain.* M. Menzin. *Comptes Rend.* 1897, 681.

THE author refers to M. Hartman's experiments on steel and other metals (*Acad. des Sciences*, 1894), which proved that deformations under compression, flexion, &c. were produced in a series of waves in discontinuous zones, geometrically distributed according to well-determined laws.

The author's experiments on aluminium, nickel-steel, delta-metal, and brass, show that they obey the same general laws as steel, but he notes certain interesting peculiarities.

1. *Aluminium.*—When a bar is stretched, regular waves are produced on the surface in two conjugate systems, as with steel. But while the waves in the steel form a network of narrow furrows, in the aluminium a series of broad bands appears for a moment; the bands are not permanent, however regular the strain, but appear intermittently in certain zones, equally inclined to the direction of the strain. This phenomenon continues until one of the waves is converted into a permanent groove. Finally the bar is ruptured either along such a groove, or following the bisectrix of the angle formed by two conjugate depressions, if they are of equal depth. As in the case of steel, the undulations produced on the two sides of the bar are exactly the same, so that they are not mere surface phenomena.

2. *Nickel-steel* (25 per cent. nickel).—The phenomena are similar, the surface being covered with a network of lines, all making the same angles with the direction of strain. These lines are produced almost continuously, and sometimes they take the form of an X the branches of which have the same inclination as those of the isolated lines. Finally a permanent groove is produced in some well-determined zone of undulations. Outside this zone, the bar retains no traces of molecular movements. When the strain is relieved for an instant, the undulations in progress are abruptly arrested, but are reproduced when the strain is again exercised.

3. *Delta Metal.*—The same peculiarities as nickel-steel, but with this difference, that the X form undulations are more numerous and are propagated more continuously. The rapidity of propagation is a function of the speed of transmission of the strain, and the number of oscillations increases with this speed of transmission.

4. *Brass.*—With hammered brass a series of clearly defined rectilinear deformations is produced immediately and abruptly, which rigorously preserve the same angle with the direction of strain, and spread over the surface as the strain increases—not lines in the geometric sense of the word, but veritable depressions, of sometimes many millimetres, and which exhibit a network of very fine striæ parallel to the two conjugate systems of deformation.

#### PATENTS.

*Gold and Other Metals from their Ores, A New or Improved Process for Extracting, especially applicable to the Treatment of Refractory Ores.* J. A. Bruce-Fraser, London. Eng. Pat. 9524, May 5, 1896.

THE gold is extracted by nascent chlorine produced by any convenient means. In the process cited, the pulverised ore is roasted if necessary, mixed with about 5 per cent. by weight of barium peroxide, placed in a closed vat with sufficient hydrochloric acid to cover the mixture, and allowed to stand for 12 hours. Water is then added till the solution contains only 3 per cent. of acid, and the whole is well agitated, allowed to settle, the liquor decanted, and the gold precipitated by a ferrous salt. If silver be present, common salt is added to the solution to dissolve the chloride, and the metal is precipitated with copper, whilst any copper present may be removed by scrap iron.—A. W.

*Metals on Silver Coatings, An Improved Process for Depositing.* The Improved Electric Glow Lamp Syndicate, Ltd., London. From C. Schwabe, Berlin. Eng. Pat. 9656, May 6, 1896.

IN the deposition of copper or other metal on a thin film of silver deposited on glass for glow lamps, &c., it is found that the silver, together with the copper on it, flakes or scales off. This is now found to be due to traces of the silvering solution, contained in the pores of the silver and between it and the glass, reacting with the solution used for depositing the copper and producing movements of the liquid, heat, &c., which cause the silver film to become torn. To prevent this the author adds to the depositing solution of the copper or secondary metal, the remains, or the essential constituents of the same, of the silvering solution in adequate quantity, thus neutralising the secondary bath and preventing its reaction with the traces of primary solution in the pores of the silver.—A. W.

*Metal or Admixture of Metals [Alloys of Al, Cu, Sn, Zn, Ag, and Sb Regulus], A certain New or Improved.* W. Van Wart, F. W. Popp, and J. J. Bradley, all of Birmingham. Eng. Pat. 12,287, June 5, 1896.

TO obtain an alloy which shall give sound castings, and which shall be of very low specific gravity, but strong and workable, and suitable for spinning, stamping, rolling, casting, and drawing,—85 to 100 parts of aluminium are alloyed with 1 to 7 parts of copper,  $\frac{1}{2}$  to 5 parts of tin, 1 to 7 parts of zinc, 1 to 5 parts of silver, and  $\frac{1}{4}$  to 1 parts of antimony. The copper and silver are first melted together (or the copper alone, if silver be omitted from the mixture), the zinc and antimony are then stirred in very

rapidly, the aluminium is then gradually introduced, and when the whole mass is thoroughly alloyed, the pot is removed from the furnace and the tin is added.—W. G. M.

*Alloys, Chromium and Similar, Impts. in the Manufacture of.* E. A. G. Street, Paris. Eng. Pat. 13,111, June 13, 1896.

ALUMINIUM is added to molten iron or steel in quantity just insufficient completely to deoxidise it; the desired proportion of chromium is then introduced, with a slight surplus to effect the removal of the last trace of oxygen. In this way a perfectly fluid metal is obtained free from aluminium.—W. G. M.

*Bessemer or Thomas Process for the Treatment of Low Qualities of Crude Iron, Impts. in the.* L. Pszczolka, Krompach, Upper Hungary. Eng. Pat. 13,451, June 13, 1896.

THE difficulty of refining white crude iron, containing insufficient silica and phosphorus to produce the necessary heat in the ordinary process, is now overcome by blowing compressed and heated air upon, or laterally into, the crude iron bath. The hot air may be obtained from a Cowper blast-furnace apparatus, working at the usual blast-furnace pressure, and the furnace may be a converter or hearth of any kind. The surface of the metal is freed from slag in places by the blast, and thus exposed to direct oxidation by the hot air.—A. W.

*Metallic Alloy, An Improved Manufacture of.* C. Parnacott, London. Eng. Pat. 14,006, June 24, 1896.

THE composition is as follows:—Copper, 85·15 parts by weight; iron, 2·15; magnesium, 1·0; zinc, 10·45; tin, 1·10; sal-ammoniac, 0·5; and "crude tartar," 0·1. The copper and iron are mixed by melting and pouring the former into the latter in a crucible, adding the sal-ammoniac, and well stirring. The magnesium is then added. The zinc and tin are melted together and poured into this mixture through a tube which dips under its surface. The crude tartar is then added, the whole well stirred, and the alloy cast. The result is a yellowish-red or yellowish-gold metal possessing great tensile strength and elasticity.

—A. W.

*Annealing Metals, and for other like Purposes; Impts. in Muffles for.* Elkington and Co., Ltd., Birmingham, and H. T. Fellows, Accock's Green. Eng. Pat. 16,756, July 28, 1896.

THE improvements "consist essentially in arranging in or combining with a closed chamber, or arranging under a closed hood, a rotating or stationary bed or pan, in which bed or pan the ignited fuel for the heating of the metals to be annealed, &c. is placed, the combustion of the fuel in the said bed or pan being maintained by a bottom forced draught of air supplied to the said bed or pan." "The combination with annealing muffles of the kinds just referred to, of a cooling chamber provided with a slowly rotating table," is also claimed. On this table "the heated articles from the annealing chamber are placed."—A. W.

*Steel, Impts. in the Manufacture of.* J. de Moya, Paris. Eng. Pat. 5926, March 6, 1897. (Date claimed under International Convention, Aug. 10, 1896.)

SODIUM chloride, calcium carbonate, and plumbago are added to the bath of Bessemer or open-hearth steel before pouring, in order to produce a fine-grained homogeneous metal. In the case of an 8-ton basic Bessemer converter, 12 kilos. of NaCl and 20 kilos. of CaCO<sub>3</sub> are added immediately before removing the slag. The converter is rocked with the blast on to expel fumes; it is then allowed to remain at rest for about two minutes; the slag is removed, ferro-manganese is added to the extent of half the quantity ordinarily used; and finally 6 kilos. of plumbago are introduced, the converter being still at rest with the blast turned off. After a minute the charge may be poured. In the acid Bessemer converter, the same process is followed, excepting that the slag is not removed. The use in the open-hearth furnace is similar to that above described.—W. G. M.

**Lead and Lead-Zinc Ores, Impts. in the Method of Decomposing.** A. J. Boulton, London. From S. Ganelin and J. Block, both of Philadelphia, U.S.A. Eng. Pat. 1179, Feb. 16, 1897.

The sulphides of lead and zinc are mixed with an equal weight of calcium (or magnesium) chloride, both ingredients being thoroughly pulverised. They are then treated for two days in the cold with concentrated commercial hydrochloric acid (22° B.). Galena is thus decomposed and the lead forms a double chloride with the calcium or other chloride, and under these circumstances does not prevent the further attack upon the galena; the hydrogen sulphide evolved is sufficiently free from hydrochloric acid gas to be used for conversion into sulphuric acid. The added chloride accelerates the solution of zinc sulphide in the ore, and for this purpose, ammonium chloride is to be preferred. With ammonium chloride, the greater part of the zinc is left insoluble in the acid liquid, probably as a double salt. After drawing off the solution, from which zinc and silver are to be recovered by existing processes, the ore is dried to remove  $\text{H}_2\text{S}$  and  $\text{HCl}$ . Instead of employing a solution of hydrochloric acid, the ore may be mixed with calcium chloride and from 2 to 4 molecules of  $\text{H}_2\text{O}$  per molecule of  $\text{CaCl}_2$ , and then treated with hydrochloric acid gas in the cold. Or the  $\text{HCl}$  gas may be passed through a concentrated solution of a chloride containing the ore in suspension. The ease with which the reaction of the hydrochloric acid with the sulphide is completed is due to the porosity of the double chlorides formed, rather than to chemical energy; for less heat is evolved by the action of hydrochloric acid upon galena when calcium chloride is present than when the sulphide is alone; and, further, a chemically inert, porous substance, such as coke or pumice, may be substituted for the calcium chloride. Lead zinc ores often contain silicious matter, and are then capable of being treated without foreign admixture.

The chloride residue is freed from hydrochloric acid by exposure to the air for two or three days, or by blowing air through the mass, and is then leached with water, which dissolves the added alkaline earth metal chloride and all soluble chlorides formed, including silver chloride, which becomes dissolved in the resulting salt solution. The residual lead chloride may be used either as it is left, or after recrystallisation (following filtration) from a boiling alkaline earth metal chloride solution, the mother-liquor being used repeatedly for successive recrystallisations. The purity of the crystals depends upon the strength of the liquor, calcium (or other) chloride being deposited with the lead chloride; but this impurity is soluble in water, and may thus be removed. The presence of zinc chloride in the solution is advantageous, as it renders the lead chloride less soluble, the maximum of insolubility being attained when the solution contains 12 per cent. of the former compound. There are 15 claims.—W. G. M.

**Alloy of Copper and Iron, Manufacture of an.** A. F. M. V. Baron. Eng. Pat. 4202, Feb. 16, 1897.

A COPPER-IRON alloy of any desired composition is made by heating the copper in a plumbago pot to a temperature varying between a cherry- and a very bright red heat. A mixture of two-thirds of oxalic acid and one-third of resin is then added, in the proportion of (say) 50 grms. of mixture per 100 kilos. of alloy. When the copper is melted the iron is added. Other organic acids which evolve carbon monoxide and carbon dioxide on heating, may be substituted for the oxalic acid. A comparatively soft alloy would contain 5 per cent. of Fe; as the iron is increased up to 50 per cent. the alloy becomes harder. These alloys may be rolled or drawn with a facility which depends upon the proportion of iron.—W. G. M.

**Copper, Obtainment of, from Ores and other Copper-bearing Substances; An Impt. in.** W. Noad and W. Agate, both of London. Eng. Pat. 8873, April 7, 1897.

The crushed ore is agitated with a (5 per cent.) ferric chloride solution until the copper is dissolved. The liquid is then run into a second vessel, in which is a porous com-

partment containing sodium chloride solution and a zinc or other electro-positive metal electrode; in the outer vessel is a copper or other electro-negative electrode, to complete an electric circuit. When the deposition is completed the solution is returned to the first vessel to treat another batch of ore. Sulphide ores must be roasted prior to treatment.

—W. G. M.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A.)—ELECTRO-CHEMISTRY.

**Ferric Chloride Battery.** F. W. Küster. Zeits. Elektrochem. 3, 1897, [17], 383—385.

This is a criticism of a recent paper (see this Journal, 1897, 245), in which H. Pauling recommends a form of battery wherein iron, carbon, and ferric chloride are used, and in which the following reactions are said to take place when the battery is producing a current:—

Küster says it is *a priori* improbable that ferric chloride should be formed at the anode and should then give up part of its chlorine at the cathode; and he adduces an experiment to show that only ferrous (and not ferric) chloride is produced when the cell is in action. He further criticises Pauling's sanguine estimate of the economical working of the cell. Such iron as would be used in making these cells always contains finely divided carbon or iron carbide. One would therefore expect local action to be set up between these particles and the iron in which they are embedded. The following experiment shows that such wasteful action does occur:—A cell consisting of a carbon plate, a clean iron plate of 40 sq. cm. surface, and a 50 per cent. solution of ferric chloride was closed through a galvanometer for 40 minutes. The galvanometer showed that during this time 0.297 ampere-hour had flowed through it. On the assumption that it forms ferric chloride, the corresponding amount of iron dissolved should be 0.297 grm.; or 0.310 grm., on the assumption that it forms ferrous chloride. As a matter of fact, the iron plate was found to have lost 1.66 grm. in weight. Thus only one-sixth of the iron dissolved was usefully employed in producing current. And when simply left to stand by itself in the (partially reduced) ferric chloride solution for another 40 minutes, the iron plate suffered a further loss in weight of 1.2 grm. In Pauling's battery the iron is used as the containing vessel; and it would probably come to grief before long, even on open circuit.

—D. E. J.

### PATENTS.

**Electric Batteries [Using Air, &c.] and Appliances connected therewith, Improved.** L. B. Atkinson, Penarth, and F. G. Treharne, Llanishen. Eng. Pat. 8906, April 28, 1896.

The object is the production of electrical energy from coal, coke, or other fuel, or from hydrocarbons, solid, liquid, or gaseous. The inventors say: "Broadly, our invention is as follows. We form a battery or cell having electrodes [metals, or oxides of metals; fused or moving electrodes] which have a different affinity for oxygen: we place these in an electrolyte [one or more, or mixed: solutions of salts, or fused salts, as hydrates, nitrates, chlorates, phosphates, borates, or oxides (lead, &c.); porous partitions may be employed] capable of transferring oxygen. The electro-negative element is oxidised by means of atmospheric air, either directly, or indirectly by means of a chemical transfer. The electrodes now being connected by a conductor, an electric current is set up, the electro-negative element loses oxygen, the electro-positive element is oxidised. To maintain the action, the electro-negative electrode is oxidised at the expense of atmospheric oxygen, the oxidised portion

of the electro-positive electrode is deprived of oxygen or reduced by carbon monoxide, hydrogen, hydrocarbon gas, or mixed producer gases derived from carbonaceous or hydrocarbon fuel."—J. C. R.

*Electrolytic Decomposition of Liquids [Alkali Chlorides, &c.], Impts. in or connected with Apparatus for the* G. and G. W. Bell, Liverpool. Eng. Pat. 11,133, May 22, 1896.

THE improvements relate to "covered-in or hollow anodes, that is, anodes having a cover or roof above, by which all the gas liberated at the surface under such roof or cover is collected, and in which the gas so collected is conveyed away by suitable conduits." Apparatus for the decomposition of liquids (alkali chlorides, &c.), with the cathode chamber directly above the anode chamber and a diaphragm separating the two, is fully described and shown. Eng. Pat. 20,540 of 1895 (this Journal, 1896, 908) is referred to.—J. C. R.

*Electrodes [Detachable] for Electrolytic Purposes, Impts. in.* E. A. G. Street, Paris. Eng. Pat. 11,338, May 23, 1896.

"A CATHODE for use in the electrolysis of substances producing a solid deposit on the negative electrode, the characteristic feature of this cathode being that after the deposit having been effected thereon, it can be reduced in size—the object being to enable the deposit to form a film or layer which can be very easily detached; the said cathode being for this purpose formed by a thin sheet, preferably of metal, wound one or several times upon itself; the reduction of the cathode in size being subsequently obtained, after the deposit has been formed thereon, by winding the sheet constituting the cathode upon itself."—J. C. R.

*Anodes [Carbon-Platinum] for Electrolytic Purposes, Impts. in.* P. Jensen, London. From H. C. F. Störmer, Christiania, Norway. Eng. Pat. 14,393, June 29, 1896.

THE claim is for "carbon anodes for electrolytic purposes, coated or covered with foil of platinum or other metal which is not acted upon by the electrolyte."—J. C. R.

*Secondary Electric Batteries, Impts. in. [Reticulated Frame.]* M. O. A. Garreau, Paris, France. Eng. Pat. 16,270, July 22, 1896.

THE electrodes are composed of a reticulated frame formed of an alloy of antimony and lead, the rectangles of which are filled with flat or corrugated bands or strips of lead of suitable length, the edges of which are connected midway of their length and held in place by an autogenous solder, so as to limit their expansion to the direction of their length. Each plate is provided with long legs or supports of insulating material which is unaffected by the electrolyte, and they are wrapped in parchment paper to secure the active material. When set up in the cell, the plates are pressed closely against each other.—G. H. R.

*Pasted Plates for Accumulator Batteries, Impts. in. [Helically wound Cores.]* J. and H. H. S. Vaughan-Sherrin, Ramsgate. Eng. Pat. 16,516, July 25, 1896.

EACH element is in the form of a bar, and consists of a solid or tubular core of ebomite or other suitable non-conducting material, round which is wound helically a lead strip, which may be crimped or plain. Round this conducting strip, and in the opposite direction, is wound an insulating helix of ebomite or the like, and the active material is pressed into the interstices between the parts. The non-conducting core may be dispensed with, and the elements be formed of a cruciform, straight, or twisted lead conductor, round which is wound an insulating helix, the interspaces being filled with active material as before. An inner springy insulating helix may be wound between the core and the conductor, or between the coils of the latter. The electrodes may consist of one or more of the elements suitably connected up.—G. H. R.

*Ozone or Ozonised Air, Impts. in Apparatus for the Production of.* A. Verley, Paris, France. Eng. Pat. 17,228, Aug. 4, 1896.

THE apparatus consists of a sheet of polished copper or the like and a sheet of glass or equivalent material silvered on the side furthest from the metal sheet, the two sheets being separated by distance pieces capable of adjustment, and so arranged that the air in passing between them to the outlet at the centre is forced to take a spiral or other circuitous course, during which it is ozonised. The two metal sheets are respectively connected to the poles of a source of electric supply, and means are provided for cooling the apparatus, either by a stream of water or of other liquid passing over the surface of a slate table on which the copper sheet rests, or by the expansion of compressed air or other gas.

—G. H. R.

*Electric Accumulators, Active Material for the Plates [Pyridine, &c.] or Electrodes of; The Manufacture of an Improved.* S. Hammacher, Berlin. Eng. Pat. 17,161, Aug. 4, 1896.

THE claims are for the manufacture and use of active material for the electrodes of accumulators by mixing an oxide or oxides of lead [minium or red lead or litharge] with substances or bodies of the pyridine group [pure pyridine or crude, as in bone- or animal-oil] in the presence of water, whereby the said oxides of lead are solidly bound together, so that after drying they may be subjected to the "forming" process.—J. C. R.

*Electric Accumulators or Storage Batteries [Felt between Electrodes], Impts. in.* D. Young, London. From La Société Anonyme "Accumulateur Eclair," Brussels. Eng. Pat. 22,069, Oct. 5, 1896.

"THE manufacture of an electric accumulator in which the active material or paste is scraped off above the surface of the grids, and the plates or electrodes so formed are placed one against another, with a sheet of felt or analogous material intercalated between them . . . ."—J. C. R.

*Plates (Planté) for Secondary Batteries or Accumulators, Impts. in or relating to. [Lead Ribbon.]* H. T. Cheswright, Paris, France. Eng. Pat. 9563, April 14, 1897.

THE plate consists of a series of lead strips or ribbons, plain, corrugated, or embossed, arranged in groups, and depending from a conducting bar, the lower ends being left free. To prevent any chance of short-circuiting between the plates, these are enclosed in a framework, bands, cage, or perforated envelope of insulating material.—G. H. R.

*Electrodes for Electric Accumulators, A Manufacture of. [Use of Butyrate or Lactate Paste.]* E. Marckwald, Berlin, Germany. Eng. Pat. 9913, April 20, 1897.

THE plates consist of frames or moulds filled with a paste made of a basic lead salt formed by stirring into a 10 to 12 per cent. aqueous solution of butyric acid, 5 to 7 times the percentage of finely powdered lead oxide. When the plates have hardened, they are formed in dilute sulphuric acid in the usual way. Instead of butyric acid, the same proportion of lactic acid or of the two acids may be employed.

—G. H. R.

*Electrodes for Electric Accumulators, A Manufacture of. [Use of Milk Paste.]* E. Marckwald, Berlin, Germany. Eng. Pat. 9914, April 20, 1897.

THE electrodes consist of gratings, frames, or moulds filled with a paste made by mixing 1 kilo. of lead oxide or of red lead with about 200 c.c. of milk. The hardening of the paste may be accelerated by careful warming, and the formation of the plates is then completed in the usual way.

—G. H. R.

*Accumulator Plates, An Improved Process for the Manufacture of.* W. A. Boese, Berlin. Eng. Pat. 10,254, April 24, 1897.

1. "A PROCESS for the manufacture of accumulator plates, which consists in causing red lead to be reacted on within

a frame by an organic or inorganic acid which combines with red lead or which decomposes the red lead, forming an insoluble or hardly soluble lead salt, with or without the use of a binding material, in order to produce a mutual wedging of the particles of the mass in the frame by the resultant expansion of the reaction product."

2. "A process for the manufacture of accumulator plates, which consists in mixing red lead with acetic acid and a binding material soluble in the latter, such as asphalt or catechin, and allowing it to react in a frame divided into one or more parts."

3. "A process for the manufacture of accumulator plates, which consists in dry lead formed into plates being inserted in sulphuric acid, or an acid having a similar reaction, and allowing it to stand therein uninterruptedly, the acid consumed being replaced until the said plates are sufficiently hard."

Eng. Pats. 11,532 of 1892 and 4610 of 1895 are referred to (this Journal, 1893, 527, and 1895, 757 respectively).

--J. C. R.

### (B).—ELECTRO-METALLURGY.

*Alloys, Electrolytic Methods of preparing Metallic.* J. Walter. Zeits. f. Elektrochem. 3, 1897, [17], 385—388.

SUPPOSE the object is to prepare an alloy of a heavy metal, such as lead, with a light metal, such as sodium. The most obvious method is to use fused lead at the bottom of a crucible as the negative electrode; on this is placed the fused salt, into which the positive electrode (carbon) dips. The process goes on satisfactorily at first; but, after a while, globules of sodium rise to the surface in increasing quantity, and then burn or unite with the chlorine. Furthermore, after the crucible has cooled, it is found that at the bottom we have nearly pure lead, and just below the fused salt an alloy which is very rich in sodium. The alloy, being very light, does not mix readily with the bulk of the lead. The author schedules a number of methods for overcoming this difficulty. The methods depend upon one or other of the following principles:—I. Mechanical stirring of the metal which forms the negative pole. II. The use, as negative electrode, of a fluid (mercury) or fused metal, which is allowed to trickle through the electrolyte. III. In some cases the temperature of the electrolyte (fluid or fused) may be kept below that of the metal to be alloyed, but above that of the alloy; the metal may then be suspended as the negative electrode in the liquid electrolyte. The alloy as formed, melts away and a fresh surface of the metal is continually exposed. IV. In other cases the salts of two metals which are to form the alloy can be arranged in separate layers; the negative pole can be raised or lowered so as to dip alternately into the one layer or the other, while the positive pole makes contact with both. Or temporary changes can be made in the composition of the fused electrolyte; e.g., if the alloy contain an insufficient proportion of a certain metal, a salt of that metal can be brought into contact with the cathode for a time. Among the applications of these methods described, the following may be given as examples:—A. Preparation of the alloy mentioned at the beginning of this abstract. The fused lead is stirred up by passing through it hydrogen or nitrogen (from a tube provided with minute apertures), so that the alkali metal meets fresh surfaces and forms a uniform alloy with the lead. B. Preparation of an alloy of aluminium and tin from the double chloride of aluminium and sodium. C. Preparation of silicon-bronze by electrolysis of water-glass. D. Preparation of aluminium-bronze by electrolysis of cryolite and copper chloride.—D. E. J.

## XII.—FATS, OILS, AND SOAP.

*Cholesterin Bromides.* C. Cloez. Comptes Rend. 124, 864—866.

WHEN bromine is added to cholesterin, both in carbon bisulphide solution, the body  $C_{25}H_{41}OBr_2$  is obtained; but

if to 5 grms. of cholesterin in 50 c.c. of carbon bisulphide a solution of 2 c.c. of bromine in 10 c.c. of carbon bisulphide be gradually added, small crystalline needles form abundantly when 2 c.c. of the bromine solution have been added, and redissolve as more is added, disappearing completely when 4.3 c.c. (the amount needed to convert all the cholesterin into dibromide) is reached.

This suggests the formation of a mono-bromide; but in point of fact, the compound is probably a molecular combination of cholesterin with the dibromide—

Solvents could not be found to separate the new body into these two substances; but support is given to this view of its constitution from the fact that it is easily obtained by mixing carbon bisulphide solutions of cholesterin and its dibromide in molecular proportions.—J. T. D.

*Castor Oil, Chemistry of.* H. Meyer. Pharm. Zeit. 42, 326.

See under XX., page 632.

*Stearin in Spermaceti, A Simple Test to Detect.* E. Hirschsohn. Pharm. Central-Bl. 38, 2.3.

### PATENTS.

*Spent Lyes, An Improved Process for the Purification of.* C. H. Simpson and F. H. T. Allan, Wakefield. Eng. Pat. 16,129, July 21, 1895.

THE improvement claimed is the treatment of spent lyes with electricity. The lyes are neutralised, although this is not absolutely essential, and a current of electricity is passed through the liquid, an iron cathode and anode being used. The strength of the current should be not less than  $2\frac{1}{2}$  volts. By this treatment the lower and less stable compounds of sulphur and oxygen are oxidised, and the arsenic and organic impurities are precipitated. The result is a very pure form of lyes suitable for concentration and distillation for the manufacture of pure glycerin.—W. P. S.

*Liquid Soap, A New or Improved.* T. H. Bateman, London. Eng. Pat. 24,090, Oct. 29, 1896.

THIS consists of a solution of soft soap in spirits of rosemary and lavender oil, with the addition of glycerin.

120 parts of soap are digested in 30 parts of a solution composed of 20 parts of spirits of rosemary and 1 part of lavender oil. After filtration, about 10 per cent. of glycerin is added to the compound.—W. P. S.

*Glycerin, Improved Method of Concentrating.* E. A. Rueh, Paris. Eng. Pat. 1355, Jan. 18, 1897. (Under Internat. Convention, First Foreign Appl., July 18, 1896.)

THIS method is one for distilling glycerin liquors under pressure. The liquors, clarified and filtered as usual, are introduced into a copper digester of any suitable shape, and provided internally with a coil, through which a current of steam circulates. The contents of the digester are quickly raised to boiling point at the desired pressure, which should not be less than 6 kilos. above the pressure of the atmosphere.—W. P. S.

*Oil from Peat, A Process for the Production of.* F. Rapp-Rosenthal, Berlin. Eng. Pat. 9314, April 12, 1897.

THIS process has for its object the production of an oil from peat, and consists in boiling the peat for about an hour, if necessary with the addition of water, and then pressing it in bags. The resulting liquid is allowed to stand until an oil separates, which oil is then drawn off from the extract. The oil may be used as an embrocation.—W. P. S.

### XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS, &c.

#### PATENTS.

*Drying White Lead, Colours, and other Powdery Granular or Nodular Substances; Impts. in Apparatus for.* T. C. Sanderson, Norwich. Eng. Pat. 7868, April 14, 1896.

The apparatus consists of a long closed heating chamber containing a travelling band or a series of trays for carrying the material through the apparatus. Heating pipes are arranged in side chambers, communicating with the main chamber at top and bottom, so as to heat and circulate the air. The material is fed into the apparatus through steam-heated rollers, and when the dust is noxious, the dried material is discharged into a hopper in connection with a dust chamber and exhaust fan.—O. H.

*White Lead [Dutch], Impt. in the Manufacture of.* A. H. Sandiland, London. Eng. Pat. 10,462, May 15, 1896.

SINCE "Dutch" white lead as usually prepared contains a certain amount of soluble lead salts, this portion of the substance dissolves and is wasted during the washing and grinding in water. To prevent this loss, the inventor adds 7 oz. of an alkali carbonate or hydrate, or a mixture of the two, to every 20 galls. of the water employed in the treatment of the material; claiming by this device to obtain an increase of 0.5 per cent. in the yield.—F. H. L.

*White Lead [Dutch], Impts. in the Manufacture of.* H. C. Webster and R. Crawford, Glasgow. Eng. Pat. 14,428, June 30, 1896.

SOME or all of the earthenware pots usually employed in the manufacture of white lead by the "Dutch" process are replaced by similar vessels made of lead, in order to avoid loss by breakage, &c.—F. H. L.

*[Coloured] Zinc Pigments, Impts. in the Manufacture of.* A. M. Clark, London. From W. Hampe and C. Schnabel, Clausthal, Hanover. Eng. Pat. 17,931, July 31, 1896.

THESE pigments are prepared by intimately mixing together zinc sulphate with 6 to 30 per cent. of the sulphate of some other metal (or metals) which yield a coloured oxide—e.g., nickel, cobalt, manganese, and iron—drying the whole, adding finely-divided carbon, and igniting carefully at 650° C. In the manufacture of the more delicately tinted samples, the zinc sulphate should be purified by stirring zinc oxide into its solution, and passing a current of chlorine through it, by which process the iron, cobalt, and manganese present as impurities are thrown down.—F. H. L.

(B.)—RESINS, VARNISHES.

#### PATENT.

*Treatment of Wood, Paper Fabrics, Fibres, and like Materials, to render them Impervious and Inalterable by Moisture and Climate and other Influences; Impts. in the.* S. Bennett, London. Eng. Pat. 12,695, June 9, 1896.

AFTER being thoroughly dried, the materials to be treated are first coated with a mixture of equal quantities of castor or linsed oil and turpentine, and then with 1 part of nitro-cellulose, 2 parts of turpentine, and 3 of ether-alcohol or amyl acetate. Or the two operations may be combined by adding 5 to 20 per cent. of nitrocellulose in a state of solution to the oils selected.—F. H. L.

(C.)—INDIA-RUBBER, &c.

#### PATENT.

*Treatment of India-rubber, Gutta-percha, and their Compounds; Impts. in the.* E. Horning and S. Hansel, Vienna. Eng. Pat. 9464, April 13, 1897.

AS vulcanised india-rubber and gutta-percha, if not freed from excess of sulphur, gradually become hard and brittle on exposure to air or high temperatures, the inventors prefer

to precipitate gelatin from its aqueous solution, mix it with 10 to 50 per cent. of "vulcanised oil," dry the whole, and incorporate it with the rubber; the proportions employed depending on the quality of the rubber, and also on the filling materials contained in the mass.—F. H. L.

### XIV.—TANNING, LEATHER, GLUE, SIZE.

*Fermentation Phenomena in Tan Liquors.* F. Andreasch. Imp. Research Laboratory, Vienna. Der Gerber, 527, 186; 534, 275.

THE preceding research has shown that the tannins have no direct antiseptic action. The carbon required by the micro-organisms is drawn from the soluble non-tannins. The yeasts draw their supply of carbon from the carbohydrates, and cease to grow as soon as these are used up. For the bacteria, the supply of N is of more importance than C.

The amount of non-tannin in a tanning material is a fairly exact measure of the quantity of acid it will produce. In an unused tan liquor only alcohol and acetic acid are usually produced, lactic organisms not being able to develop for want of sufficient N.

In order to ascertain the exact measure of fermentable substances, the author conducted a series of experiments on nine different materials, the results of which are given in Table I. The materials employed contained an average amount of tannin, non-tannin, and sugars as compared with the mean of a large number of samples.

N was added in the form of mineral salts, so as to introduce no fresh carbon; but, as a matter of fact, peptones and similar albuminous bodies furnish no carbon to the bacteria.

The organisms used were: (1) A *Saccharomyces*; (2) a lactic bacillus; (3) a lactic yeast. The alcohol was estimated by Duclaux's physical method (*Comptes Rend.* 70). Owing to the many ethers produced, it gives slightly erroneous results; but if the amount of alcohol be compared with the percentage of sugars, the results are concordant enough. The sugars and lactic acid were estimated as before described (this Journal, 1897, 248 and 249).

It will be seen that the whole of the sugar is decomposed by alcoholic fermentation, and that the lactic bacteria can transform almost all the non-tannin into lactic acid. These results hold good for all materials examined by the author. The dextrins and soluble starches of some materials (pine and hemlock barks, canaigre) are as important a source of carbon for bacteria as the sugars are for the yeasts.

In practice, the fermentation takes place in two stages: (1) all the sugars are fermented by yeasts; (2) fresh hides coming into the partly decomposed liquor, supply the lactic and other bacteria with nitrogen, and enable them to continue the production of acid from other carbon compounds than the yeasts can utilise.

In accordance with the table, p. 621, the materials examined may be arranged in order of acid-producing value, as follows:—1. Pine bark. 2. Sumac and oak bark. 3. Myrabolams. 4. Valonia and hemlock bark. 5. Oak wood. 6. Knopperrn and quebracho wood. Knopperrn liquors are remarkable for a short, quick fermentation, owing to the presence of an easily fermentable sugar. Glucose may be added with advantage to such materials as quebracho, but addition of fresh pine bark produces a quicker fermentation, owing to the fact that suitable yeasts exist on the bark, which cause a natural fermentation, like that of wines. Alcohol has been added with success to the liquors of an Italian sole-leather tannery when the acidity was insufficient. The author has investigated the action of addition of glucose, alcohol, and pine bark to tan liquors; the results are shown in Table II.

The research, so far, may be summed up as follows:—

1. In the alcoholic and acid fermentation of tan liquors, the carbon is derived from the non-tannin, in some cases the whole of it being used up.

2. The tannin is *not* decomposed by the micro-organisms taking part in the fermentation.

*Huill's Iodine Solution, The Behaviour of Tannic Acids and Tannic Extracts towards.* C. Boettinger. Chem. Zeit. 21, [16], 450.

See under XXIII., page 640.

#### PATENTS.

*Soluble Colloids of the Gelatine Class, Impts. in Formation and Preparation of.* E. J. Mills, Glasgow. Eng. Pat. 17,536, Aug. 8, 1896.

This comprises modifications of or improvements on the process described in Eng. Pat. 8847 of 1895 (this Journal, 1896, 462) for converting gelatin, or a gelatin-containing, or gelatinous substance, into a compound permanently soluble in cold water.

One method is to take 100 parts of glue, preferably comminuted, 5 parts of slaked lime, and 100 parts of water. These are stirred together and allowed to remain at the ordinary temperature until perfectly soluble in cold water. With glue of good quality and moderate hardness, the conversion takes place in a week or ten days.

An alternative method is to dissolve the glue in water with the aid of heat, and allow the solution to cool and become a jelly. The comminuted jelly is mixed thoroughly with the slaked lime. In the course of an hour or more, perfect liquefaction will have been attained.

Instead of caustic lime, other caustic alkali earths may be employed, or caustic alkalis or their carbonates.

—L. J. de W.

*Tanning of Hides and Skins, Impts. in the Preparation for and.* E. O. Daniel, London. Eng. Pat. 11,111, May 4, 1897.

In the process of preparing hides and skins for tanning, a revolving drum is used having an entrance and exit for liquid, and the continuous passage therethrough of liquid in which the hides or skins are treated previous to going through the "bating" process; and the internal periphery of the drum may be fitted with stays or struts, or backwardly curved pegs or projections, or with pegs and struts combined, to assist in keeping the hides or skins separated from each other.

Another portion of the invention relates to the method of application of the tanning solution. The hides or skins are allowed to soak in a comparatively dilute tanning solution in suitable vats or pits, and the solution is gradually increased in strength; or the hides or skins are put into a stronger solution or gradually stronger solutions. Up to this point there is no novelty in the treatment; but the skins are next placed in a drum containing a strong tanning solution, which, when revolved, brings the solution into contact with every part of the hides or skins, by which greatly improved results are obtained.—L. J. de W.

#### XV.—MANURES, Etc.

##### PATENT.

*Fertilised and Fertilising Materials, Manufacture of Improved.* C. H. Thompson, Teignmouth. Eng. Pat. 9794, April 15, 1897.

In the manufacture of an improved fertiliser of the kind described in Eng. Pat. 20,971, 1894 (this Journal, 1894, 1246), to serve as a substitute for earth, in which plants may be grown without earth, or raised from seeds, or struck as cuttings and brought to maturity quicker than in earth, or to be used as "mulching" or manure—peat-moss is used, or other suitable fibrous or spongy material, impregnated with a "solution" of soot, gypsum, bone-meal, or the chemical or functional equivalents of these substances, phosphoric acid, potash (pearlash), and nitrate of soda. After boiling, the fibre is removed, dried, and fermented, so as to cause a complete chemical interchange of the ingredients.

The liquor is also fermented with yeast or other ferments, after the addition of saccharine matter, to produce a concentrated liquid fertiliser.—L. J. de W.

#### XVI.—SUGAR, STARCH, GUM, Etc.

*Synthesis of Cane-Sugar.* L. Marchlewski. Rocznik Akad. Umiej. Krakowskiej. 1896.

CANE-SUGAR may be obtained by the action of acetochlorhydrose upon the potassium salt of *d*-fructose. The reaction is expressed by the following equation:—

Pure acetochlorhydrose is dissolved in alcohol, and to the solution freshly prepared sodium levulose is added. The mixture is left to stand for about seven days at ordinary temperature; to complete the reaction it is heated for half an hour on the water-bath; next the potassium chloride formed is filtered off, the filtrate evaporated at 80° C., and the residue dissolved in boiling water. The solution obtained is next treated with a solution of  $\text{Ca}(\text{OH})_2$ , and the gradually formed precipitate filtered off, stirred in some water, and decomposed with  $\text{CO}_2$ . The  $\text{CaCO}_3$  obtained is filtered off, and the filtrate purified by means of  $\text{Ca}(\text{OH})_2$  in a similar manner. Finally, the aqueous solution of the sugar is extracted with ether in order to remove the saccharin, and then evaporated *in vacuo*. After some days' standing, the cane-sugar formed, crystallises in the well-known forms. All the reactions and physical properties agree with those of natural cane-sugar.—L. M.

*Juice and Liquor [Beetroot], Filtration of.* L. Beaudet. Bull. Assoc. Chim. 1897, 14, 967-969.

Most sugar manufacturers are convinced of the necessity of filtering the juice carefully after each purification, but in some factories this is only incompletely carried out, either for want of space or on account of cost. The author thinks that no expense should be spared to effect this object, for fear of redissolving precipitates already formed, through alteration of temperature or alkalinity.

Contradictory results were obtained on examining liquors which were produced from diffusion juice filtered before carbonating, but this failure is attributed to the filtration having been too slow.

The filtration of the juice in filter presses is effected either with or without decantation. Decantation has the disadvantage of cooling the juice, and is thus one cause of the formation of calcium salts. As soon as a precipitate is formed, it should be separated as rapidly and completely as possible, and the juice should be exposed as little as possible to the air. This condition is far from being realised in the case of decantation.

One of the principal difficulties in filtration arises from incomplete carbonating, or from the juice being allowed to cool after the first carbonation. Another cause is the use of well- or river-water for washing, instead of distilled water, the former rapidly obstructing the pores of the cloths, through deposits which are formed.—L. J. de W.

*Juice [Beetroot], Filtration of.* L. Beaudet. Bull. Assoc. Chim. 1897, 14, 973-977.

THE filtration of the juice should be applied at the following stages:—(a.) After the filter presses from the first carbonating. This operation is indispensable; for, whatever care may be exercised at the presses, the juice will still contain precipitates in suspension. The juice of the first should be completely freed from precipitate before going to the second, or the whole principle of double carbonating is disregarded. (b.) To the filtration of the juice of the second carbonating previously passed to the filter press. (c.) To the filtration of the juice of the third carbonating. (d.) To the liquors between the second and third effects. This, although not indispensable, is to be recommended. (e.) To the filtration of liquors from the multiple effect.—L. J. de W.

*Diffusion Juice, Conditions of Inversion of Sugar in Acidity of Beetroot and Diffusion Juice.* H. Pellet. Bull. Assoc. Chim. 1897, 14, 1038—1040.

JESSEN concludes (this Journal, 1897, 451) that diffusion juice possesses an invertive power, and that this power varies from year to year with the temperature to which the juice is heated, the method of culture, and the soil on which the roots are grown, &c. Consequently, from the point of view of diffusion, the greatest attention should be paid to every circumstance which may increase the invertive power, and extremes should be avoided. The author, however, sees no disadvantage in strongly heating a juice if the duration of diffusion is thereby lessened, or if the practical conditions are otherwise favourable. The best guide is to follow the quality of juice obtained by different methods of working, examining not merely the raw diffusion juice, but every stage down to the low products. It is not always diffusion juices of greatest purity which give masscutes easy to work and the highest yield. It is only after purification by lime and carbonic acid that we can have an indication of this by chemical analysis and the physical properties of the masscutes.

It is not acidity alone that determines the invertive power of a diffusion juice, but it is probably the result of all the foreign matters acting on the sugar. In diffusion juice from the sugar cane, much higher acidities are found than in that from beetroots, and no formation of invert sugar results. This has been verified the last few years in several factories in Java, Guadeloupe, and Egypt.

According to Panzenko (Bull. Assoc. Chim. 1897, 829), diffusion juice has a higher acidity than that of the beet slices from which it is produced. This does not appear to be the fact. On reducing 100 grms. of coss-ettes into pulp suitable for instantaneous cold aqueous digestion, and making up the liquid to a litre, it will be found to be of the same acidity as diffusion juice of the same dilution, the total acidity being calculated to 100 grms. of sugar, and not to 100° Brix. In actual work the varying character of the water used may influence the acidity very considerably. Beetroots also are not always equally clean, and if the earth adhering to them be of a calcareous character, the acidity of the juice may be affected. Unless all these conditions are taken into account, it is not possible to conclude with certainty that there is formation or destruction of acidity in the diffusion process.—L. J. de W.

*Potato Starch and Potato Flour.* Saare. Papier Zeit. 1897, 30, 1059.

POTATO starch, of which 200,000 to 300,000 tons are annually produced in Germany, is sold in two qualities. The best, termed "superior," is singularly white, glossy, and pure, and consists of large grains, being the first to deposit in the settling tanks. The deposits are lower in quality in succession, until only a brown powder is deposited, known as slime sand.

Potato flour is made by grinding and sifting the dried potato starch. If dried on frames in a state of repose, it is known as "burdle" starch, or if dried on endless webs kept in motion, it gets small-grained, and is known as "machine" starch.

The best quality of starch is used for the manufacture of starch sugar and dextrin. A soluble starch has been recently made, giving in water a clear colourless solution. Another recently introduced article is ozone gum and ozone starch, in which the aromatic odour is removed, rendering the product similar to wheat starch. Attempts have also been made to obtain a nitro starch as an explosive, but without much success. Some French chemists have also tried to obtain alcohol from starch.

Good starch must be free from chlorine and acids, and the moisture must not exceed 20 per cent. It must be of a pure white colour, slight shades of yellow, grey, or blue indicating insufficient washing or bad drying. Potato starch has a peculiar smell, due to volatile oils, which may be extracted by alcohol. A sour smell indicates wrong treatment in manufacture, and the starch is deteriorated as a foodstuff. The gloss of starch, which is much esteemed, depends on the size of the grains—the larger the grains the better the gloss; and the determination of the average

diameter of the grains under the microscope forms a good test for starch: a superior article having an average diameter of grain of 35.5  $\mu$  ( $\mu = \frac{1}{25,400}$  mm.), the "Ordinary Prima" starch 32.5  $\mu$ , the ordinary or "Prima second" 21  $\mu$ , and the inferior kinds 17 to 12.5  $\mu$ . The condition of the grains also affects the gloss, some kinds of starch which show a tendency to agglutinate having no gloss.

Of considerable importance is the amount of impurity present, consisting of such foreign substances as coal dust, potato skin, soot, sand, iron particles from wheels, slag from water, particles of wool, &c. The amount is ascertained by smoothing a sample on white paper, and counting the number of particles in 1 sq. cm. The superior contains 15 to 30; average starch, 27—170; while some kinds contain as many as 800 upon 1 sq. cm. These particles affect the manufactories, showing in paper as dark dots, &c. The nature of the impurities ("stippen") may be sometimes ascertained by means of the microscope. A sample is spread smoothly out on white paper, and under the microscope the number of fine particles of foreign substances is counted in 1 sq. cm. A "Superior" starch should only contain 15 to 30, whilst "Medium Prima" may contain 27 to 170. In potato flour, hard lumps sometimes appear, due to bad drying.

If not free from acids, especially mineral, it is liable to affect clothes when used as a dressing material. The use of acids in the manufacture is necessary, but they must all be removed again. Calico-printers test for acid by printing on coloured cotton a pattern with the starch paste and observing whether any change of colour takes place. To test for acids, drops of neutral Bordeaux red litmus solution are sprinkled upon the starch. Superior starch turns the colour light blue, most starches do not affect it, slightly acid ones turn it wine red, and strongly acid ones turn it to an onion-red colour. The test for acid by titrating the alcoholic extract with decinormal alkali is not accurate, owing to the starch grains retaining some of the acid in their parenchyma. The following is recommended:—25 grms. of starch are ground up with 25.30 c.c. water and titrated with decinormal KOH. The alkali is added by drops, until a drop of the solution placed on filter paper prepared with litmus gives the same colour as a known neutral starch. If 100 grms. of starch need 5 c.c. of  $\frac{1}{10}$  normal KOH, the slight acidity should be mentioned; if 8 c.c. KOH be required, the starch is acid, and if more than 8 c.c. be required, the starch is strongly acid.

The amount of water in starch varies from 13 to 30 per cent.—S. P. E.

*Starch, Control of the Manufacture of.* Hébert. Bull. Assoc. Chim. 1897, 14, 1003—1011.

THE results of the extraction of starch from potatoes appear to be identical in France and Germany; yet, in spite of the efforts made in both these countries, smaller factories, in the case of what is considered "good work," still leave behind 60 to 65 per cent. of starch on the solid matter of the pulp, and the author has found pulps containing 75 per cent. The various mills brought out as improvements on the old rasping process have reduced the loss to 45 per cent., but at the cost of a considerable amount of power. No great advance can be expected in apparatus for subdivision of the material, but fermenting the pulp for several months allows 15 to 20 per cent. of inferior starch to be recovered. The fermentation having altered some of the starch grains, this secondary starch is scarcely fit for anything except the manufacture of glucose; and the offensive smell communicated to the waste water gives trouble. Woelker attempted to cultivate ferments which would attack only the cellulose and leave the starch untouched; rasping is thus totally suppressed. The author adopted Woelker's process, and in three days obtained a pulp containing 18 per cent. of starch; the starch obtained, however, deposited incompletely and was always greyish and difficult to dry, but no lesion of the grains could be detected under the microscope. A large French factory, after trying a similar process, abandoned it in favour of rasping.

Few French factories are prepared to admit that they lose 15 to 20 per cent. of starch from defective methods. Antiseptics are little used, whilst in Germany the use of sulphurous acid and calcium bisulphite is general.

The determination of starch in potatoes by saccharification with acids is far from exact from the point of view of the starch manufacturer, as a portion of the cellulose is said to be saccharified, and the sugars, glucoses, carbohydrates, and soluble starches present, are counted as starch. The error from this cause may amount to 2 per cent. of the total dry starch. Maereker and Saare found in potatoes 0.58 to 6.07 per cent. of soluble carbohydrates calculated on the starch, and one of them found 35 per cent. in immature tubers. Aimé Girard showed by photomicrography that when potatoes sprout, starch is rendered soluble and passes into the expanding portion of the tuber. Baudry's method of estimation is equally inexact, for, in addition to the bodies above mentioned, the dextrins produced, affect the rotatory power of the starch rendered soluble by the salicylic acid. He has proposed a correction for pectin which has passed into solution, of 0.2 when the acid is used alone, and 0.35 when zinc chloride is also added. The solution is boiled for 50 minutes. As tubers of the same variety may show differences of 10 to 12 per cent. in starch, it is doubtful if the other constituents are more fixed.

After maturity the tubers rapidly change, starch becoming soluble and nitrogenous matters being transformed partially into solanine, the proportion of 41 mgrms. of solanine per kilo. for healthy tubers rising rapidly to 90 and 112 mgrms. The eyes contain 2,700 mgrms. per kilo. Baudry's method is rapid, the figures obtained being constantly higher than those given by saccharification and titration with Violette's solution.

For the determination of starch by density, preference should be given to an apparatus operating on 5 to 10 kilos., and the tubers should be cut to avoid air bubbles. The tables established in Germany by Behrend, Hildebrands, Maereker, and Heidepriem (the latter being most highly approved) are far from being universally applicable. The author is of opinion that in each district observations should be made over several years and special tables prepared for each region. 170 samples of blue giant of the Nord gave by Heidepriem's table 2 per cent. less than by saccharification. 29 samples from the Oise showed 3 per cent. too high.

For control of the pulps and waste water, the author saccharifies by acids, defecates by acetate of lead, and, if necessary, filters through char. Maereker's method for the examination of pulps demands much time and manipulation, and Baudry's is slow and liable to considerable error.

Many starchworks have been closed for want of a practical method of dealing with the waste water, 10 to 13 litres of water being rejected per kilo. of potatoes worked.

—L. J. de W.

*Carbohydrates, On the Thermal Phenomena attending the Change of Rotatory Power of Freshly Prepared Solutions of Certain; with some Remarks on the Cause of Multi-rotation.* H. T. Brown and S. Pickering. *Proc. Chem. Soc.* 1897, [181], 129—130.

During an investigation of the thermal changes attending hydrolysis under enzyme action, the results of which are described in the next abstract, it became necessary to inquire whether the change in the multi-rotation of certain sugars is attended with any heat disturbance, as it is now well known that, at any rate, dextrose and maltose are liberated by hydrolysis in the "birotatory" state. The authors find that the changes of rotation experienced by dextrose, levulose, and milk-sugar in passing from the optically unstable  $\alpha$ - to the optically stable  $\beta$ -form, are accompanied by distinct thermal effects, which, although taking place slowly in the solutions under ordinary conditions, can be produced, like optical stability, almost instantaneously by the addition of traces of an alkali. A full account is given of the apparatus employed, of the method of experiment, and the nature of the corrections to be applied. In the cases of dextrose and milk sugar, there is a liberation of heat accompanying the change of rotatory power; with levulose there is a very decided absorption; and with maltose no thermal disturbance is recognisable. The following are the values obtained:—

	Per Grm. of Sugar.	Per Grm.-Molecule.
Dextrose.....	+ 0.588	+ 106
Levulose.....	- 1.64	- 835
Milk-sugar.....	+ 0.19	+ 34
Maltose.....	0	0

The authors discuss the various explanations which have been given from time to time to account for multi-rotation, and consider that their experiments favour the view that it is conditioned by chemical rather than physical causes, and that Fischer is probably correct in his suggestion that dextrose, for instance, in passing from the optically unstable to the optically stable modification in solution, passes from the aldehyde,  $C_6H_{12}O_6$ , to the heptahydric alcohol,  $C_6H_{14}O_7$ . They believe, however, that the analogy which Fischer suggested, of the change of a lactone into its acid, is less close than that afforded by the gradual change of acetic aldehyde, in contact with water, into ethylidene glycol, where the CHO group becomes CH(HO)<sub>2</sub>.

*Carbohydrate Hydrolysis, On the Thermo-Chemistry of. (I.) The Hydrolysis of Starch by Vegetable and Animal Diastase. (II.) The Hydrolysis of Cane Sugar by Invertase.* H. T. Brown and S. Pickering. *Proc. Chem. Soc.* 1897, [181], 130—131.

THE attempts made to determine the thermal effects of hydrolysis have hitherto been confined to indirect methods, based on the heats of combustion of the hydrolysable substance and its products. Such methods, it is shown, cannot give results of any real value, as the thermal changes to be measured, are considerably within the experimental errors of the combustion values.

The paper describes the results obtained by direct measurement of the heats of hydrolysis of starch and of cane sugar. Lintner's soluble starch was for the most part used, as there are certain mechanical difficulties in employing starch paste in the calorimeter, owing to its viscosity. The hydrolytic agents used for starch were: (1) malt diastase, (2) pancreatic diastase, (3) Taka diastase, and (4) saliva. With malt diastase, the heat of hydrolysis was found to be +2.60 calories per gm. of amylin converted into maltose. The amount of heat is proportional to the water fixed, and is independent of the molecular complexity of the amylin attacked. The breaking down of the starch molecule prior to hydrolysis does not appear to be attended with any thermal disturbance.

With pancreatic diastase the heat liberated per gm. of amylin hydrolysed amounts to +1.8 cal., a value sensibly less than that deduced from the action of the malt diastase. With Taka diastase the heat disturbance is still less than with the other two agents. The possible causes of these differences are discussed.

Cane sugar was hydrolysed with invertase, and was found to give a thermal effect of +11.21 cal. per gm. of cane sugar inverted when the products were in the optically stable  $\beta$ -form, and 13.34 cal. per gm. at the moment of liberation of the products, i.e., when they are in their "birotatory" or optically unstable form. It is the larger number which correctly represents the heat of hydrolysis of cane sugar.

*Glucose, A Study of the Direct Production of, from Raw Material.* F. Lippmann. *Chem. Zeit.* 21, [46], 458—460.

THE author reviews the different modern methods of producing glucose from raw material without previous production of starch. In Europe the potato only need be considered. In order that the preparation of glucose from potatoes without the previous manufacture of starch may be practical, the following conditions must be fulfilled:—

1. The final product must be of equal value to that prepared from pure starch.

2. A larger quantity of final product must be obtained from the same quantity of raw material than by preparing starch from it and then working this intermediate product.

3. The cost must be no greater than by the starch process.

These conditions are difficult when one considers that purified starch is almost a chemically pure body, whereas the potato has the following average composition:—

Water, 73–78 per cent.; protein, 2–2.5 per cent.; fat, 0.1–0.3 per cent.; starch, 18–22 per cent.; cellulose, 1–2 per cent.; ash, 1–1.5 per cent.

The author passes by processes previous to 1831, in which the finely divided potatoes directly underwent inversion. The action of the  $H_2SO_4$  on the cellulose and colouring matter of the potatoes, produced a bad-coloured and bad-smelling product. He then discusses the processes of Anthon (Diöglers Polyt. J. 1859, 154, 69) Cordis-Verniceis, Bondonneau (La Féculerie, 1893, 2, 188), Pieper (Chem. Zeit. 1891, 18, 1956, and Ger. Pat. 77,158, Aug. 22, 1891), Lassmann (Wagner, Die Stärkefab., 2 Aufl., 383), Colas, and Davoine (Dist. Franç. 1890, 474).

Bondonneau's method gives a product of better quality than the others, though Pieper's is very worthy of notice. The principle of Bondonneau's method consists in washing out the albuminous bodies with pure water from the very finely divided material; this is then pressed and the pulp inverted with dilute acid under pressure, but below the boiling point; the object being to prevent the decomposition of the cellulose.

From 1,000 kilos. of pressed pulp (75 per cent.  $H_2O$ ), Bondonneau obtains 3,000 litres of glucose syrup of sp. gr. 1.030.—J. T. W.

#### PATENTS.

*Refining of Sugar [Barium Peroxide]. Process for the Complete.* G. Ranson, Phalempin, France. Eng. Pat. 11,790, May 30, 1896.

"This is a process to obtain colourless syrups, derived from raw beetroot or cane sugars, by taking from them the chief part of the coloured molecules, by oxidising those that are poor in oxygen or that do not contain any, and by reducing those which are rich in oxygen." Barium dioxide, capable of being regenerated several times according to the quantity of syrup to be treated, is used either alone or by preparing a special solution of it with the addition of a very small quantity of bone-black. From 2 to 5 per cent. of the solution at 20 to 25° B. is added to the syrup "at a temperature of triple effect," mixed, and left in contact until the whole of the gas has been given off, and then carbonated. Or, for refining raw products sufficiently pure—say of the commercial type known as No. 3—the sugar is not dissolved, but broken into grains of the size of the refined product. A clairce is also prepared with No. 3, at 36° B., which is treated cold with about 3 per cent. of barium dioxide in the form of oxidised water, and  $\frac{1}{2}$  per cent. of fine or impalpable bone-black.

The barium carbonate is attacked with nitric acid to give carbonic acid and barium nitrate, which will be easily decomposed by heat and yield pure baryta, and the nitric acid be recovered.

For making tablets, the decolorised and refined syrup is run into a mould, or some modified forms thereof, in which wedges and vertical blades or partitions and reglets, with perforated sheet-iron plates placed horizontally, form a series of rectangular partitions, on which a space is reserved for brushing off and adding the quantity of claire determined upon. Under the mould is situated a liquoring table, with which, by means of a vacuum, the operations of liquoring, sucking out, and the like are carried on when the syrup is partly solidified. There is a modification to suppress the horizontal perforated iron sheets, and an apparatus to be placed on the mould to convey damp air to facilitate the rapid detachment of the tablets, and a lifting table with an arrangement of screws to remove the vertical plates. The metal blades are loosened from the tablet block by a lever press. There are six sheets of drawings.—L. J. de W.

*Molasses, Impt. in Extracting Sugar from, by means of Barium Hydroxysulphide, and Recovering the latter.* W. Feld, Honningee a Rhein, Germany. Eng. Pat. 16,441, July 24, 1896.

In extracting sugar from molasses by means of barium hydroxysulphide alone, there is this disadvantage, that only

half the barium introduced is utilised in producing barium saccharate, whilst the other half passes into the residual liquid, from which it has to be recovered.

In the present invention this disadvantage is obviated by the use of a mixture of barium hydroxysulphide with an equivalent quantity of alkali hydroxide, or by treating the molasses with these reagents successively.

Sulphuretted hydrogen is separated from the residual liquor containing alkaline sulphhydrate by means of carbonic acid and heat, and the carbonised residue is again converted into alkali hydroxide by the action of caustic lime.

—L. J. de W.

*Adhesive Compounds, Impts. in or relating to.* A. J. Boulton, London. From C. M. Higgins, Brooklyn, U.S.A. Eng. Pat. 9108, April 9, 1897.

THE object of this invention is to produce an adhesive compound in the form of a dry or nearly dry powder, put up in bulk or in small packages or masses, which may be used for the production of sizes, pastes, or mucilages when dissolved in hot water, and will give the effect of manufactured dextrin, or a superior effect, at much less cost than dextrin, and in a manner which will enable the desired quality of the resulting paste or size to be more readily controlled and determined by the user or consumer than is possible with manufactured dextrin.

To this end a new article of manufacture is produced, consisting essentially of raw or unconverted starch or flour in a dry or powdered state, impregnated with some digestive or converting acid, or agent adapted in the presence of heat and moisture for the conversion of the starch or flour into a soluble or dextrin state, so that when such impregnated starch is dissolved in hot or boiling water it will produce a solution of actual dextrin, or more or less approaching actual dextrin, according to the temperature and time employed in making such solution, which is under the control of the user. This acidulated starch powder is put up in suitable receptacles or packages, and included in the same package a separate mass of neutralising alkaline powder duly proportioned to the contained mass of acidulated starch, but enclosed in a separate receptacle or envelope. After a quantity of the impregnated starch has been dissolved in hot water, a due proportion of the alkaline powder may be added to neutralise the acid and perfect the product. It is preferred to impregnate the starch with sulphuric acid and boric acid, and to form the neutralising powder of caustic soda or borax in a powdered form. The use of a solid dry digesting acid, such as oxalic acid in a powdered form, is also claimed, and the addition of an essential oil perfume or flavouring substance to the neutralising powder.

—L. J. de W.

#### XVII.—BREWING, WINES, SPIRITS, Etc.

*Kilned Malt, Storage of.* L. Aubry. Zeits. f. d. ges. Brauw. 20, [25], 265–267.

COMPARATIVE experiments were made on the influence of temperature during storage, by filling three adjacent bins, each of 12 cb. m. capacity, with malt, Nos. 1 and 2 (the latter jacketed to prevent radiation) being filled with malt fresh from the cleaning heap, three days after unloading from the kiln, at a temperature of 119.7° F., and the former left open for 40 days, the temperature then registering 70–25° F. Bin No. 3 was filled from the same heap, 16 days after the others, and also left open, No. 2 being closed all the time. The temperature in 1 and 3 remained below 70° F. during the six months' duration of the experiment, whereas that in No. 2 only fell to 99.25° F. at the end of three weeks, and remained above 77° F. the rest of the time.

When analysed, the warm-stored sample revealed a rather lower water-content than the others, and the percentages of extract and maltose were also lower, but that of nitrogen higher; these conditions being, however, reversed in the wort after mashing. In the matured beer, the attenuation and percentage of alcohol were lowest in this sample, and conversely, the content of residual extract and maltose was greatest. The actual attenuation of the three

beers, in numerical order, was 50.0°, 48.0°, and 51.3° respectively, but there was no apparent difference in their flavour, brilliancy, gas content, &c.

The conclusions drawn by the author are to the effect that the filling of malt warm into silos of not excessive dimensions will not lead to any deterioration of flavour or production of rancidity, provided the conditions permit of gradual cooling and subsequent storage at normal temperature. If, however, the temperature be allowed to remain at over 100° F. for long, bad results may ensue, particularly with malt containing much moisture, since oxidation and other reactions, resulting in alterations of flavour, are thereby facilitated. The free circulation of air is also a factor of some weight, and accounts for the rancidity of malt stored warm in sacks. Exposure to air, as in the case of sample No. 3, favourably influences the rendering soluble of the extract and the clarification of the wort.—C. S.

*Brewing Utensils, Disinfecting Power of Sodium Carbonate Solution in Cleaning.* L. Steuber. Zeits. f. d. ges. Brauw. 20, [19], 253—255.

From experiments made on the action of 5 per cent. and 10 per cent. solutions of pure calcined sodium carbonate on culture- and wild-yeasts, it appears that cells of both kinds of yeast are able to withstand 15 minutes' exposure to the 5 per cent. solution at 45° C., but are all killed at 55° to 60° C., whilst the 10 per cent. solution accomplishes the same result at 5° lower. Hot water used alone, with an exposure of half an hour, was without effect at 50° C., but above 60° C. destroyed the vitality of the cells.

Similar tests were applied to yeasts containing spores, the resisting powers of which were found to be greater, some even withstanding a short exposure at 75° C. In its influence on this form of growth, hot water is almost superior to the soda solution, and the action of the two strengths of the latter is nearly identical. Since fission fungi appear equally able to resist the action of soda (a germ of this order having been found to grow 14 days in a 5 per cent. solution in the laboratory), the disinfecting properties are presumably low, and it is therefore deemed advisable, when employing soda in brewery practice for cleaning out pipes and utensils, to make the minimum exposure 30 minutes and the minimum temperature 80° C., and to supplement its more mechanical property of loosening adherent matter by the sterilising influence of steam, with or without the conjunction of calcium sulphite, bleaching powder, &c.—C. S.

*Amylomyces Rouxii, and other Starch-fermenting Moulds.* J. Sanguinetti. Ann. Inst. Pasteur, March 1897; La Bière, 5, [4], 49—52. (See also this Journal, 1897, 348 and 154.)

From the results of comparative experiments made with *Aspergillus oryzae*, Gayon's *muco alternans*, and *Amylomyces Rouxii*, the author finds that the energetic saccharifying power possessed by all three is greatest in *A. oryzae*, the *Amylo. R.* taking second place. On the other hand, the latter leaves behind in a given time a larger amount of unconverted carbohydrates than either of the others—a circumstance which, combined with its greater fermentative power, renders it alone, out of the three, suitable for industrial employment, whether for the direct fermentation of starchy bodies or for utilising distillery residues.—C. S.

*New Vinegar Bacterium.* Zeidler. Centralbl. für Bakt. und Parasitenkunde, 1896, No. 23—24.

This bacterium has been named *Thermobacterium aceti*; it converts alcohol into acetic acid, and subsequently converts a portion of the acetic acid into carbonic acid and water. If sugar is also present in the solution, a fixed acid—lactic acid—is also produced. In appearance it greatly resembles Kohn's *bacterium termo*. In old cultures, spirillum forms are frequently found. When grown in wort gelatin, glistening transparent patches are formed and the gelatin is not liquefied; as it is aerobic, it only grows on the surface.

The most suitable temperatures are between 70° and 85° F. It will not grow below 40° or above 120° F.

As this bacterium cannot grow without a free supply of air, there is little risk of its causing any trouble in beer.

—A. L. S.

*Laccase: Its Oxidising Power, Influence of Manganese upon.* G. Bertraud. Comptes Rend. 1897, 124, 1032—1035.

In his researches (this Journal, 1895, 374 and 1074; 1896, 561) on laccase, the author has already remarked that this oxidising ferment is relatively rich in manganese (0.1 per cent. Mn). Continuing his investigations, he has made the interesting discovery that the oxidising power of the ferment varies directly as the percentage of manganese present. The coincidence is not merely accidental, but is shown to be due to a specific accelerating influence of manganese upon laccase. Comparative experiments were made with a specimen of laccase (derived from lucerne grass), containing only a minute trace of manganese, the volume of oxygen absorbed by a solution of hydroquinone (this Journal, 1895, 1074) under the influence of the ferment, being measured.

	Volume of O absorbed.
1. Manganese alone (blank experiment).....	0.3 c.c.
2. Laccase alone .....	0.2 c.c.
3. Laccase + 1 mgrm. of manganese as sulphate....	6.3 c.c.

The manganese cannot be replaced by other metals. A number were tried, but in no case was any accelerating action observed. This fact enormously increases the physiological importance to be attached to manganese, especially when it is considered that traces of this metal exist in many plants.—H. T. P.

*Rum, A Bacterium in.* V. H. Veley, M.A., F.R.S., and L. J. (Mrs. V. H.) Veley. (Communicated by the Authors.)

It is well known that considerable pecuniary loss has resulted to the manufacturers of rum in Demerara owing to "faultiness" in certain samples. In these, assessed as at 42 o.p. (equivalent to 74.6 per cent. alcohol by weight), when examined with a magnification of 1,200 diameters, cocci surrounded by gelatinous envelopes were found, not only in deposits, but also disseminated through the liquid. These cocci multiplied by division, and increased with greater or less rapidity, when transferred to suitable media. So far as the study of the life-history has proceeded, it appears that the bacterium belongs to the group of Coccaceae, adopting the classification of Zopf. The organism has been found in 19 samples obtained from various sources.

Previous writers on "faulty rums" have observed in them flocculent precipitates, which have hitherto been considered as of a chemical nature; they, however, consist of aggregates of cocci in various stages of development. As these have been found invariably in "faulty" but never in "sound" rum, it seems reasonable to conclude that they form one of the principal causes of faultiness.

The authors hope shortly to publish a full account of the micro-organism based upon the investigations of its life-history, as exhibited by cultures in various media.

—V. H. V.

*Alcohol, Denaturing of.* E. Barillot. Comptes Rend. 124, [21], 1163.

THE Swiss revenue authorities employ, for rendering alcohol non-potable, the "oils of acetone" resulting from the destructive distillation of the acetates and other organic salts of the alkaline earths. The author shows that this method is useless, since by treating the alcohol so denatured with bisulphite of sodium, the added oils are almost wholly precipitated and may be removed by simple filtration. This filtrate, on fractional distillation, gives 70 per cent. by volume of potable spirit. The minute trace of acetone which this distillate may still retain is readily removed by treatment with iodine or chlorine in alkaline solution, after which the recovered spirit is undistinguishable from duty-paid alcohol.—J. O. B.

*Wines, Loss of Colour in (Casse des Vins), Properties of the Ferment Producing.* P. Cazeneuve. *Comptes Rend.* 1897, 124, 781—782.

In a preceding note (this Journal, 1897, 347), the author has shown that the disease known as "casse des vins" (attended by loss of colour and bouquet) is due to a soluble ferment—*œnoxydase*—under the influence of which, the colouring matter of wine is oxidised and precipitated, and the ethers, &c. similarly changed or destroyed. The ferment, although greatly weakened by contact with strong alcohol, retains its activity unimpaired for months in dilute alcoholic solution (9 per cent.) or in wine. Like other ferments, however, its activity appears to diminish in proportion to the amount of work done by it. *œnoxydase* is powerfully affected by sulphurous acid: a mere trace (0.008 grm. per litre) of the latter added to wine entirely prevents the development of the "casse," the action of the acid being a directly destructive, and not merely a preservative one. On the contrary, formaldehyde, in comparatively large doses (0.08 grm. per litre), has no restrictive influence whatever. The colouring matter of the wine, although precipitated by the formalin, is, nevertheless, oxidised and rendered insoluble in dilute sulphuric acid, in which reagent the precipitate, produced by formalin in a sterile wine, is readily soluble. The activity of *œnoxydase* is neither increased, nor diminished, by blowing a current of oxygen or ozone through its solution.—H. T. P.

*Maltine Wines [Malt Wines], Preparation of.* J. Sauer. *Zeits. f. Spiritusind.* 1897, 20, 156—157.

THE so-called Maltine wines do not in the least resemble a mixture of wine and beer, as is frequently alleged. They owe their peculiar character to the method of preparation, which differs essentially from that adopted in the production of beer, and especially in the following points:—(1.) In the lactic fermentation of the malt wort. (2.) In the selection of the yeast and the degree of attenuation brought about by the latter. (3.) In the method of storage. The wort is prepared by the infusion method from the best barley malt, and under conditions yielding the highest proportion of maltose. A pure culture of the lactic acid bacillus is added to the wort, and the lactic fermentation allowed to proceed for 18—24 hours at 50°—51°; when the acidity has reached 0.6—0.8 per cent., the product is sterilised by heating it to 88—94°. It is subsequently cooled and a pure culture of a specially selected wine yeast is introduced. Fermentation proceeds vigorously and the fermentable sugars soon disappear; more maltose in the form of malt extract is then added, and at a later stage pure cane sugar is introduced. By carefully conducting these fermentations, it has been possible to obtain over 19 per cent. by volume of alcohol. When at the end of the fermentation the yeast has settled and the wine is clear, the latter will still possess a decided malt aroma, which has yet to be removed, and this is effected in 3—4 weeks by warm storage and free contact with air.—A. K. M.

#### PATENTS.

*Pasteurising Liquids, New or Improved Apparatus for.* J. H. W. Ortmann and C. W. C. Herbst, Hainburg, Germany. Eng. Pat. 21,203, Sept. 28, 1896.

THE object is to pasteurise beer and other liquids containing gas whilst the liquid is passing from the storage or other vessel, and in such a manner that the gas is not lost. This is effected by causing the liquid to pass through a series of horizontal, undulating, ascending, and descending pipes contained in heating and cooling tanks. The gas, which separates during the heating process, is carried forward by the current of liquid, and becomes re-absorbed during the cooling operation.—A. K. M.

*Mashing and Brewing, Impts. in the Process of and Apparatus for.* L. Procházka, Turnau, Bohemia, and E. Frischauer, Vienna. Eng. Pat. 5582, March 2, 1897.

THE object aimed at is a shortening of the time required for carrying out the process previously described by one of the patentees in Eng. Pat. 17,246, 1896 (this Journal, 1896, 915). The process consists in straining the mash after having brought it to a temperature of 50—70°, boiling the grains with water to gelatinise the starch, and then reuniting the grains with the diastatic wort, in order to saccharify the remaining starch. The whole mash is finally boiled, to destroy the diastase, and the wort strained from the grains.—A. K. M.

*Drying Substances [containing Aromatic Oils], Improved Process for.* H. Humbser, Furth, Bavaria. Eng. Pat. 6065, March 8, 1897.

THIS process is more particularly intended for the treatment of substances, such as hops, which contain aromatic oils readily volatile at comparatively low temperatures. The drying is effected by means of a current of air, which is first passed through a cold chamber, in which it deposits its moisture, then through a warming chamber, from which it passes through the substance to be dried. After taking up moisture from the latter, the air is again dried in the cold chamber, and the process continued as long as desired. The temperature to which the air is raised should be below that at which volatilisation of any aromatic constituents would occur.—A. K. M.

*Non-Intoxicating Drinks, New or Improved Compounds for Making.* J. H. Brodriek, Northfield, Worcestershire. Eng. Pat. 15,004, April 7, 1897.

A FERMENTED, non-intoxicating drink, in imitation of stout, is made from the following constituents:—Hops (2 oz.), roasted malt (8 oz.), caramel ( $\frac{1}{4}$  oz.), ground ginger (1 tablespoonful), which are well mixed and compressed into a solid cake, the quantities given being sufficient to make two gallons of beverage. The cake is boiled with the water, sugar ( $1\frac{1}{2}$  lb.) added, the product is allowed to cool, and is fermented and bottled in the usual way. For imitation ale, the caramel is omitted, and crystallised, or brown or amber malt is used in the place of the roasted malt.—A. K. M.

*Mead, New or Improved Process for the Preparation of.* M. van Look, Cologne, Germany. Eng. Pat. 10,180, April 23, 1897.

PURE honey is dissolved in water, boiled, and skimmed; lemon juice is added, the boiling and skimming being continued, whilst, if desired, spices, fruit syrups, &c. are introduced and stirred in. The liquor is allowed to cool, poured off from the sediment, and yeast is then added to it. After fermentation, it is poured into a fresh cask, in which it is allowed to remain for 3—4 months or longer, after which time it is ready for bottling.—A. K. M.

*Barley, Impts. in Treating, for Alimentary Purposes, including Brewing and Distilling.* J. Dunn, Kelse. Eng. Pat. 16,671, April 27, 1897.

See under XXIII. A., page 628.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A.)—FOODS.

*Cows' Milk, On the Albuminoids of.* K. Storch. *Monatsh. f. Chem.* 1897, 18, [1], 244—281.

THE author's experiments confirm Hammarsten's conclusion that only one kind of casein is present in cows' milk. When the milk is saturated with sodium sulphate, magnesium sulphate, or sodium chloride, the precipitate is not this unaltered casein, but one of two decomposition products, each of which contains phosphorus and is of similar composition to casein. Acetic acid precipitates milk casein

in an unchanged form, and it is possible that simultaneous saturation with two of the three above-named salts might also cause it to separate without decomposition.—C. A. M.

*Milk, The Cause of the Coagulation of Heated.*

B. Bardach. *Monatsh. f. Chem.* 1897, **18**, [4], 199–216.

FROM the results of his investigation, the author came to the conclusion that the view of Cazeneuve and Haddon, that the coagulation of milk was caused solely by the action of acids produced by the oxidation of the lactose present in milk, was untenable. Preliminary experiments showed that the length of time required for complete coagulation of fresh milk was: at about 100°, about 12 hours; at 110°, five hours; at 120°, 1½ hour; at 130°, one hour; at 140°, 20 minutes; and at 150°, three minutes. The partial separation of albuminoid substances which occurred on heating fresh milk for many hours at a little below 100°, was regarded as quite distinct from coagulation proper. Throughout the subsequent experiments, the time and temperature adopted were one hour and 130° respectively, the milk being heated in an autoclave to avoid frothing.

Fresh milk coagulated by heating at this standard temperature, and the clear serum distilled, yielded, as the result of many determinations, not more than 0.003 gram of formic acid per 100 c.c. of milk. On adding 3 c.c. of 20 per cent. sulphuric acid to the filtered liquid before distillation, the amount of formic acid in 100 c.c. increased to 0.03 gram. A subsequent determination of volatile acid by distilling fresh milk, before coagulation, with the same proportion of sulphuric acid, gave 0.004 gram, the difference between this result and the preceding one being ascribed to the volatile acid produced in a state of combination by heating the milk to 130°. This amount of acid was too small to produce coagulation in the cold, which first occurred when the acidity, expressed as acetic acid, exceeded 0.13 per cent. (Hammarsten, 0.075 to 0.1 per cent.). With regard to the combined action of heat and acid, fresh milk boiled with gradually increasing quantities of acetic acid, first showed signs of coagulation when the percentage reached 0.055; but coagulation was not complete until the milk contained 0.07 per cent.—an amount considerably in excess of that of the volatile acids produced by heating the milk by itself at 130°. This result excluded the possibility of the volatile acids being the sole cause of coagulation.

Moreover, on mixing the acid liquid formed by heating a 10 per cent. aqueous solution of lactose containing 1 gram of hydrogen disodium phosphate for an hour at 100° or 130° with an equal volume of fresh milk, no alteration, beyond the discoloration, appeared in the latter, either in the cold, or on heating on the water-bath, or on once boiling. Hence the author concluded that neither the volatile acids nor the total acids produced from lactose were the exclusive cause.

The behaviour of pure casein was next studied. A 10 per cent. aqueous solution containing 1 per cent. of hydrogen disodium phosphate heated for an hour at 130° partially coagulated, but a further deposit could be obtained from the filtrate by the addition of acetic acid.

The further experiments described in the paper, proved, in the author's opinion, that the casein was so altered by heating that it could be completely coagulated by the small amount of acid formed on heating lactose solution containing an alkali at 130°, and he considered that the coagulation of milk was dependent on the simultaneous action of both these factors.—C. A. M.

## PATENTS.

*Mineral Waters, Impts. in or relating to Artificial.* J. K. Anderson, Waukesha, Wisconsin, U.S.A. Eng. Pat. 8779, April 6, 1897.

Any good drinking water is charged with carbon dioxide. Lithium carbonate and boric acid are then dissolved in separate quantities of pure water, the solutions are mixed, filtered if necessary, and the carbonated water is added in such proportion that the resulting mixture shall contain about 35 grains of lithium carbonate and 15 grains of boric acid to the gallon.—L. A.

*Barley, Impts. in Treating, for Alimentary Purposes, including Brewing and Distilling.* J. Dunn, Kelso. Eng. Pat. 16,671, April 27, 1897.

THE barley is first treated as in the ordinary operations for forming "pot" barley, and the grains are then cut or broken by means of grooved rollers. The product is sifted, moistened with water, and passed between smooth and heated rollers, the flakes obtained being finally dried in the usual way.—A. K. M.

*Milk and certain other Classes of Fresh Foods, An Improved Process and Apparatus for Preserving, by Sterilisation.* A. J. Vause, Tempe Sydney, New South Wales, Australia. Eng. Pat. 11,637, May 22, 1897.

THIS specification describes an apparatus into which milk or other article of food may be introduced and sterilised by heating, and then, without being again brought into contact with unsterilised air, may be hermetically sealed up in vessels which have been sterilised in another part of the apparatus.—L. A.

## (B.)—SANITATION; WATER PURIFICATION.

*Arsenical Wallpapers, Cause of the Poisonous Action of.* B. Gosio. Ber. **30**, 1024–1026.

A REPLY to Emmerling (Ber. **29**, 2728; this Journal, 1897, 158). No doubt there are many moulds and bacilli which can flourish in an arsenical culture-solution without giving off gaseous arsenic compounds; but some, though it may be few, certainly do evolve such compounds. *Mucor mucedo* and *Aspergillus glaucus* are among these, and Emmerling's failure to obtain evidence of such gaseous products must be ascribed to his having used unfit or unacclimatised varieties. Much more active than either of these is *Penicillium brevicaulis*; this microbe works so energetically on all arsenical compounds that it can be used for the qualitative detection of arsenic. The author has not yet been able to identify the gas given off by the action of this microbe, but it is highly poisonous—a mouse shut up with a culture of the mould in an arsenical solution died in a very short time. *Penicillium brevicaulis* develops with great rapidity on wallpapers; and this fact, coupled with the extremely poisonous character of the product, demonstrated as above stated, leaves no room for doubt that poisoning may occur through volatile arsenic compounds. Of course, this does not exclude the possibility of poisoning by arsenical dust.—J. T. D.

*Arsenical Wallpapers, Cause of the Poisonous Action of.* O. Emmerling. Ber. **30**, 1026.

A REJOINDER to the above. The volatile compound of arsenic which one would expect is arsine, but in none of the author's experiments could a trace of this be found. Gosio has failed to identify any volatile product given off; and that the mouse in question referred to, died from arsenical poisoning has not been proved.—J. T. D.

## PATENTS.

*Water-softening Apparatus, Impts. in.* H. L. Boulton and W. A. Manger, London. Eng. Pat. 11,559, May 27, 1896.

THE hard water entering the apparatus is used to drive a wheel or motor suitably connected with stirring apparatus in the reagent tank, this tank being fitted also with floats and overflow pipes for removing the clear reagent. After leaving the wheel, the water flows through a pipe into a receiver and funnel, where it mixes with the reagent. The supplies of hard water and reagent are controlled by ball-valves and floats, which are also so arranged that when from any cause the supply of hard water ceases, the valve on the reagent supply is automatically shut.—O. H.

*Impure Water and other Liquids, Impts. in the Manufacture of Materials for Use in the Filtration and Purification of.* A. Angell, Southampton, and F. Candy, London. Eng. Pat. 14,125, June 25, 1896.

A highly porous filtering material is produced by mixing the following ingredients with sufficient water to make them cohere, then stoving and baking the material and afterwards granulating it. The proportions may be varied, and instead of tar and water a solution of treacle may be used:—

Dust or powder of the porous substances described in Eng. Pats. 13,818 of 1884 (this Journal, 1886, 38) and 15,948 of 1885 (this Journal, 1886, 671), 100 parts; powdered or granulated manganese, 5 parts; dried and powdered clay, 100 parts; tar, 2 parts.—L. A.

*Sewage and other Polluted Water, Improved Preparations for Use as Precipitants in the Treatment of.* A. Angell and F. Candy, Southampton and London. Eng. Pat. 14,124, June 25, 1896.

THE essential feature of this invention is the use of nitre cake as an economical source of sulphuric acid. By grinding up bauxite with a solution of nitre cake, with or without the addition of more sulphuric acid according to the proportion of nitre cake used, a mixture of sulphate of alumina with sulphate of soda or potash is produced. This may be mixed with a solution of ferric sulphate, made by heating together ferrous sulphate, nitre cake, common salt, and manganese peroxide; or the ferric solution may be used alone.—L. A.

## (C)—DISINFECTANTS.

*Corrosive Sublimate, Disinfecting Properties of.* Borchow. *Pharm. Zeit. Russland.* 36, 162; *Chem. Centralbl.* 1897, 1099—1100.

THE varying results obtained by different workers on the disinfecting powers of corrosive sublimate are explained by the different conditions of the experiments. The author found that the cultures mentioned were destroyed by different solutions in the times stated, the conditions being those which would obtain in the disinfection of living-rooms.

	0.1 Per Cent.	0.2 Per Cent.
<i>B. subtilis</i> spores .....	6 days	5 days
Anthrax spores .....	9—10 hours	3—5 hours
<i>Staphylococcus aureus</i> ....	2½—5 "	3½ "
<i>Typhus</i> bacilli .....	50—90 minutes	30—80 minutes
<i>Diphtheria</i> bacilli .....	70—80 "	60—70 "

	0.5 Per Cent.	1.0 Per Cent.
<i>B. subtilis</i> spores .....	22 hours	12 hours
Anthrax spores .....	70—80 minutes	60—70 minutes
<i>Staphylococcus aureus</i> ....	60—70 "	50—80 "
<i>Typhus</i> bacilli .....	20—50 "	15—25 "
<i>Diphtheria</i> bacilli .....	25—30 "	15—20 "

Cholera bacilli and anthrax cultures free from spores were killed in 15 seconds. The addition of 1 per cent. of sodium chloride, 0.5 per cent. of tartaric acid, or 0.5 per cent. of carbolic acid, and also the action of light, decreased the sterilising power of the sublimate solution.—A. C. W.

*Arthritine: A New Disinfectant.* *Pharm. Zeit.* 1897, **42**, 118.

ARTHRITINE is a new proprietary bactericide and disinfectant. Its composition is represented by the formula—

and it is therefore monohydrophenolethyl-diethylenediamine-amido-acetonitrile. It is prepared in tablets, each containing 25 centigrams. It is almost insoluble in cold, but is readily dissolved in boiling water. A 1 per cent. solution prevents the development of bacteria, but the spores of anthrax bacillus retained their vitality unimpaired after contact for several weeks with a concentrated solution of arthritine. It is therefore only a weak antiseptic.

—J. O. B.

*Formaldehyde on Urea, The Action of.* *Disinfectant.* C. Goldschmidt. *Chem. Zeit.* XXI., **46**, 460.

WHEN formaldehyde is allowed to act on urea, various condensation products are formed, according as the solution is acid, neutral, or alkaline.

In acid solution the body  $C_5H_{10}N_2O_3$  is formed (Ber. **29**, 2438). When urea is allowed to stand for 24 hours with an excess of 40 per cent. formaldehyde solution, which has been rendered alkaline, a white precipitate is formed, soluble in hot water, from which it is precipitated as a jelly by alcohol. Mineral acids, on long boiling with water, separate formaldehyde; the latter is also slowly given off when the body is exposed to the air, so that it could be used as a disinfectant.

In neutral solution a mixture of a soluble and an insoluble body was formed. The latter appears to have the composition  $C_5H_{12}N_2O_3$ , the former to be the body above mentioned. The results of the analyses show that methylene urea is not formed from formaldehyde and urea, as Tollens and his co-workers suppose.—J. T. W.

*Heavy Tar Oil Miscible with Water.* Jégon. *J. de Pharm. Chim.* 1897, [6], **5**, 328.

By admixture with an alkaline resin soap, the author renders heavy oil of tar readily miscible with water, so that when diluted, an emulsion is formed in which the disinfectant is evenly distributed. The soap for this purpose is prepared from: resin, broken small, 100 grms.; soap makers' lye, 95 grms.; distilled water, 200 grms.; commercial oleic acid, 40 grms. Dissolve the resin by boiling in the lye mixed with the water, and evaporate to produce 200 grms. of resin soap, cool, and add the oleic acid. Soft soap, 80 grms., may be substituted for oleic acid, in which case, 10 grms. less of lye is taken, and the evaporation is carried only to 240 grms. Of this oleo-resin soap, 240 grms. are dissolved in sufficient heavy oil of tar to produce 1 kilo.; the soap is first warmed and intimately mixed with 400 grms. of the tar oil; the temperature is then raised, but not to boiling, until complete solution is effected; the rest of the oil is then added, and the whole covered during cooling, to avoid too great loss by evaporation. When cold the product is filtered, or strained through a cloth.

—J. O. B.

# XIX.—PAPER, PASTEBOARD, Etc.

*Paper, Specific Weight of.* Papier Zeit. 1897, 22, [31], 1098.

THE difference in weight between a square metre of papers of equal thickness may be due to the different treatment of the fibres in grinding, pressing, drying, &c., but is most probably due to the difference in the specific gravity of the fibres of the raw materials, and we are therefore entitled to speak of a "specifically light paper." A great difference may be observed between soda- and sulphite-cellulose fibres, soda-cellulose fibres being probably the lightest in use for paper-making. In sulphite pulp the ennersting matter is not entirely removed from the fibres, thus rendering them specifically heavier, and it has also the appearance of being sized, rendering it unsuitable for copying- or blotting-papers. The fibres treated with soda-lye swell, and thus appear lighter. The different kinds of wood have not much effect on the weight, though soda cellulose from hard-wood trees was found lighter than soda cellulose from pine wood. The cleaner the pulp, the lighter it will be; and considerable care should be taken when a heavy and light pulp are worked together, the latter tending to float, and sometimes it may be recognised in the paper by the fibres being on the surface, and in the direction of the running of the wire on the machine.

The editor of the *Papier Zeitung* remarks that:—The specific gravity of cellulose is 1.6, the specific gravity of pine wood being 0.4 to 0.6. As the wood fibres are freed from ennersting matters, they approach nearer to the purer cellulose, and therefore become specifically heavier. Consequently, the soda-cellulose fibres are specifically heavier than the sulphite, the paper made from soda cellulose being erroneously termed "specifically light"—a term which should be avoided, and the paper marked "light" or "thin."—S. P. E.

*Soda Cellulose, Silk Gloss of.* Papier Zeit. 1897, 22, [29], 1020.

It was observed by Mercier in 1844 that on treating cotton with soda lye, the fibres shrink, and their structure is altered from a ribbon-like form to a cylindrical one. The internal canals also disappear almost entirely—due to the thickening of the parenchymous cells. The mercerised cotton is also stronger and more elastic, and absorbs colouring matters much better than the ordinary material. Thomas and Prevost (Ger. Pat. 85,564) have found that when mercerised cotton is stretched to its original length, a rich silk-like gloss appears, which is unaffected by the drying processes. The fibres are converted into a cylindrical form like silk, and the transparency becomes increased. The gloss, colour absorption, and blotting qualities of soda cellulose are already highly appreciated; and the question whether a paper with a rich silk gloss could be manufactured by the Thomas and Prevost method is worthy of experimental trial.—S. P. E.

*Soda Cellulose, Formation of a Calcium Soap during the boiling of.* Papier Zeit. 1897, 22, [29], 1020.

At a North American soda-cellulose works, A. Zimmermann noticed the formation of black lumps of a wax-like substance, about the size of hazel nuts, which appeared in the lye, and which was insoluble in alkalis or alcohol. On analysis this substance was found to consist of raw fibres and a resinous calcium soap. The water used contained very little CaO (0.3 in 100,000); the lye did not contain a trace of CaO, the wood being therefore almost the only source of lime. The appearance was observed only when fresh pitch-pine was treated, old dry wood or fir not causing the formation. The formation was not affected by altering the strength of the lye.—S. P. E.

*Sulphite Lye, Utilisation of, as a Waterproofing Solution for Paper.* P. Remy. Papier Zeit. 1897, 22, [13], 426.

NEUTRAL or acid waste sulphite lye is treated with iron or lead salts, in quantities equivalent to the calcium salts present, when a waterproofing solution is obtained. As

lead salts are poisonous and also discolour the paper, the iron salts are the more suitable. These solutions contain salts of other metals, according to the salt added, such as calcium chloride, if ferric chloride has been used. These may be removed before treatment, either by adding sulphuric acid, a soluble sulphate, or by treating with soda or ammonia, filtering, and then adding the iron salts. As the lye is generally dark-coloured, the paper is discoloured, but this may be reduced by washing with water, until the colouring matter—a combination of iron with a substance resembling tannin—is removed, the wash water being no longer coloured. The paper is then dried. The solution of lye may be evaporated before treatment, to remove some of the free sulphurous acid.

(1.) 100 c.c. of the unevaporated lye, containing about 0.83 grm. of CaO, are treated with a solution of 2½ grms. of 66 per cent. ferric chloride or 4½ grms. of crystallised ferrous sulphate, and neutralised with a little lye, soda, ammonia, milk of lime, &c. For concentrated solutions the lye is evaporated down, the alkali added, the whole filtered, and then the iron salt added.

(2.) 100 c.c. of the lye are mixed with sulphuric acid and placed in contact with the precipitate obtained by treating 3—4 grms. of ferric chloride or 5—6 grms. of ferrous sulphate with an alkali until the sour smell disappears.

(3.) 100 parts of the lye, after evaporating down to 34°—35° B., containing about 53 per cent. of solid matter and 4.4 per cent. of CaO, are treated with sufficient water to enable the lime (precipitated by adding 9 parts of soda ash) to precipitate easily, decanting, and adding to the clear liquid a solution of 30 parts of crystallised sugar of lead.

Paper treated with any of these solutions, after being subjected to a dry heat, or 70°—130° C., is rendered waterproof (Ger. Pat. 90,798).—S. P. E.

## PATENT.

*Paper Pulp from the Broom Plant, Impts. in the Manufacture of.* H. H. Lake, London. From E. Berland and J. Girard, France. Eng. Pat. 210, Jan. 3, 1896.

THE thick wood is first separated from the small stems, and the separated materials cut up in the usual way. The material is then digested in an open vessel with weak caustic soda, and afterwards, under pressure, with strong caustic liquors. The digested material is washed first while hot, and afterwards in the cold, and bleached in the ordinary manner.

The undecorticated broom may also be treated—after being cut, as before, into small pieces—in a disintegrator provided with an exhaust fan, which draws the light fibres of the bark from the machine and discharges them into a dust- or settling-chamber.

The crushed material, fine and coarse, is boiled with dilute caustic soda solution (1°—2° B.) for one or two hours, and passed through crushing rollers, provided with rotary cleaning brushes, after which it is further digested at a low pressure with alkaline liquor. The pulp is then treated in the usual manner.

The treatment of the decorticated broom is similar. —O II.

# XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Ethylsulphuric Acid, Preparation of, from Gases charged with Ethylene.* P. Fritzsche. Zeits. Anal. Chem. 1897, 36, 303—306.

HAVING freed the gas from tar, ammonia, benzene, and hydrogen sulphide by treating it at 70°—80° C. with sulphuric acid containing not over 80 per cent. of pure acid (whereby homologues of ethylene, such as propylene, butylene, &c., if present, are simultaneously removed), the purified gas is heated to 110°—120°, by passing it through chambers maintained at this temperature. It is then conveyed to absorption apparatus, which consists of a group of scrubbers filled with acid-resisting material, over which strong sulphuric acid, heated to 116°—120°, flows in a

continuous stream. Fresh acid is introduced at the exit of the last scrubber of the series, where the gas leaves the apparatus. The acid collected at the bottom of the last scrubber is pumped into the last but one scrubber, and so on, until it reaches the first scrubber, into which the gas is introduced. By this arrangement an acid containing from 50 to 60 per cent. of ethylsulphuric acid can be obtained.

—D. B.

*Ether, Free from Alcohol; Preparation of.* P. Fritzsche. *Zeits. Anal. Chem.* 1897, **36**, 298—302.

SINCE on treating gas containing ethylene with strong sulphuric acid, ethylsulphuric acid is obtained, the direct preparation of ether therefrom is of importance. The author has devised a method which admits of the conversion of ethylsulphuric acid into ether and sulphuric acid according to the equation—

Four distilling vessels, A, B, C, and D, are connected in such a manner that the gas evolved in A passes into the bottom of the vessel B, thence into the bottom of C, and, finally, into the bottom of D. On leaving the latter, the gas is conducted through a suitable condenser, and eventually the condensed product is collected. Each vessel is charged with the same quantity of ethylsulphuric acid. A is diluted with about 35 per cent. of water, B with about 22 per cent., and C with about 10 per cent., whilst D is not diluted. The distillation is then proceeded with in the following manner:—The contents of A are heated strongly, whilst the liquid in B is only slightly warmed. The gas liberated in A is composed of alcohol, ether, and steam, and is taken up by the liquid in B. The latter, after a short interval, begins to boil. Meantime the contents of C and D are heated slightly, so that the gas from B, which is now more highly charged with ether, raises the liquid in C to the boiling point and forces the gas into D. If the acid originally employed is of high percentage—that is to say, moderately free from uncombined sulphuric acid—the ether leaving the vessel C will, from the commencement, pass unaltered through the liquid in D, whilst any alcohol, which may be carried over mechanically, is acted upon by the acid in D, and converted into ether. If, however, the acid is highly charged with free sulphuric acid, the ether and alcohol passing from C to D at the early stages of the distillation are taken up by the free acid and converted into ethylsulphuric acid, until the point of equilibrium has been reached, at which ether passes unchanged through the liquid. If the distillation has been conducted in a proper manner, the volume of liquid in D should not have been altered; B should, however, show a marked and C a moderate increase. When the acid in A has been exhausted and concentrated to such an extent that the distillation in B can no longer be effected without the aid of external heat, the operation is stopped. The acid in A is run out, the liquid in B transferred to A, that in C to B, and in D to C, after which D is charged with a further quantity of undiluted acid. The strength of the liquid in A, B, and C is then readjusted as before, and the distillation continued until A has again been exhausted. Instead of removing the charge in A after each operation, the process can be made to work continuously by using an apparatus in which the strong acid passes in a constant stream into the vessel, water being introduced gradually into the apparatus to maintain the correct degree of dilution, the exhausted acid also leaving the apparatus in a continuous stream.—D. B.

*Ether, Contribution to the Study of the Preparation of.* L. Prunier. *J. Pharm. Chim.* 1897, **5**, 513—514.

SUFFICIENT attention has not been given to the sulphonic acids and their derivatives formed in the manufacture of ordinary ether. The author makes the following statements:—1. These compounds are found in ordinary commercial ether, from which they may be extracted by washing with water, and in larger quantities in the residue of the ether manufacture. 2. They are contained in the oils formed in the rectification of the crude product. 3. The production of these compounds from ethyl sulphuric acid, especially towards the end of the process, may be experi-

mentally shown. If ethyl sulphuric acid be heated to 140° C. with sulphuric acid diluted with 3 or 4 mols. of water, and then alcohol added, a little ether is formed together with several sulphonic derivatives, some of which are sufficiently volatile to distil with the ether. 4. The sulphonic acids are produced in greater quantity when the temperature exceeds 140° C., and when the acid is not diluted. Thus, in the preparation of ethylene, when the liquid begins to darken (165° to 175° C.), it may be shown that it contains sulphonic acids in addition to ethylsulphuric acid, neutral ethyl sulphate, polyethylene hydrocarbons, and sulphurous acid. 5. Such a liquid, after dilution and continued boiling to decompose the esters and drive off sulphur dioxide, saturation with baryta, and filtering, leaves on evaporation a residue containing sulphonic derivatives. These may be oxidised by permanganate or nitric acid, and the presence of sulphuric acid shown in the ordinary way. 6. This production of sulphonic acids appears to be not without interest to the theory of the production of ordinary ether and mixed ethers.—A. C. W.

*Perfume of Flowers, A New Method for Extracting.* J. Passy. *Comptes Rend.* 1897, **124**, 783—784.

IN this process, the flowers are completely immersed in cold water, or preferably in a solution of salt, the liquid being occasionally (when charged with perfume) drawn off and replaced by fresh. From the aqueous solution, the perfume is extracted by means of ether or other volatile solvent. The process has given satisfactory results in the case of certain flowers—notably the lily of the valley—the perfume of which has, hitherto, not been isolated.—H. T. P.

*o-Brom-p-ethoxyphenylsuccinimide (Brompyrantin).* A. Piutti. *Ber.* 1897, [10], 1170—1174.

BROMINE acts upon *p*-ethoxyphenylsuccinimide at 109°, producing a derivative analogous in constitution to the bromphenacetin described by Hodurek (this Journal, 1897, 352). —A. C. W.

*Coffee, A New Alkaloid from.* Forster and Riechelmann. *Ph. Zeits. f. offentl. Chemie*; through *Pharm. Zeit.* **42**, 309.

WHEN an aqueous decoction of coffee has been extracted with chloroform and the caffeine thus removed, a body remains which does not give the murexide reaction, but which is precipitated by phosphomolybdic acid. This precipitate is mixed with milk of lime, and dried by the addition of plaster of Paris, in order to avoid the action of heat in the presence of an alkaline liquid. The dry powder is then extracted with alcohol, and the alcoholic solution evaporated to dryness. A brown oily residue results, which crystallises with difficulty, and is stated to be an alkaloid. It differs from caffeine in giving a precipitate with picric acid and in being insoluble in chloroform; also in not giving the murexide reaction.—J. O. B.

*Cosaprine: A New Antipyretic.* P. Schwarz. *Pharm. Zeit.* 1897, **42**, 131.

By treating parasulphazilate of sodium with acetic anhydride, the author has obtained a body to which he gives the name cosaprine; it occurs in well-formed white crystals having the constitution  $C_8H_4(SO_3Na)NH.COCH_3$ . It is readily soluble in water, and is stated to be less toxic than acetanilide, and at the same time an active antipyretic.

—J. O. B.

*Eucaine B: A New Cocaine Substitute.* P. Silex. *Pharm. Centralb.* **38**, 103.

THIS new cocaine substitute is closely allied to eucaine, for which Silex now proposes to retain the name Eucaine A, while he calls his newly produced compound Eucaine B. Eucaine B is benzoylvinylacetone-alkamine.

Though closely related to eucaine, and also to cocaine and tropacocaine, it is much less toxic than the last two. The hydrochloride of Eucaine B is soluble in about 20 parts of water; the solution is not decomposed by boiling, and may therefore be sterilised by heat. (See also this Journal, 1896, 679 and 745).—J. O. B.

*Eegonine, Solubility of.* (Echser de Coninek. Comptes Rend. 124, [21], 1159.

THE pure alkaloid is insoluble at ordinary temperatures in ether, acetone, petroleum spirit, chloroform, bromoform, benzene, toluene, isobutyl alcohol, ethylene bromide, carbon bisulphide, and turpentine. It dissolves in the following menstrua:—

In distilled water at 17° C. ....	1 in 4.6 fluid parts.
„ alcohol, 95 per cent., at 17° C. ....	67.0 „
„ acetic ether at 20.6° C. ....	77.0 „
„ rectified methylic alcohol at 19.2° C. ....	18.5 „
„ ethylic alcohol, 66 per cent., at 19.6° C. ....	47.0 „
„ „ „ 71 „ „ 19.8° C. ....	21.3 „
„ pure paraldehyde at 17.7° C. ....	133.4 „

—J. O. B.

*Iodothyroidine, Method of Preparation of.* M. Catillon. Nouv. Remèdes, 1897, 13, 129.

IN a communication to the Société de Thérapeutique the author suggests the name iodothyroidine for a standardised preparation of the active principle of thyroid gland, which he obtains as follows:—The fresh glands are submitted to pancreatic digestion with pancreatine and water; the residue, after washing with petroleum ether, is dissolved in dilute soda solution and filtered, the filtrate being treated with a slight excess of dilute sulphuric acid, when the active principle precipitates; this is collected and washed, the iodine content in a portion determined, and sugar of milk added to the rest in sufficient quantity to reduce the amount of iodine present to 0.0003 grm. for each grm. of iodothyroidine. This name is suggested as being more accurate and less confusing than thyroïdine, which has been applied loosely to the active principle itself and to its commercial dilutions.

—J. O. B.

*Antiartkerine.* Thoms. Apoth. Zeit. 1897, 12, 152; through J. Pharm. Chim. [6], 5, 337.

A PRODUCT under this name, introduced as a much-advertised secret remedy in Munich, has been found to be in great part composed of salicin, coloured by the addition of an extract or of a vegetable powder, possibly derived from torrefied horse-chestnuts.—J. O. B.

*Peronine: A New Sedative.* Pharm. Zeit. 1897, 42, 35.

PERONINE, prepared by Merck, of Darmstadt, is the hydrochloride of the benzylic ester of morphine, in which the hydrogen atom of the hydroxyl molecule of morphine is replaced by the alcohol radicle  $C_6H_5CH_2$ . It is represented by the formula  $C_{17}H_{19}NO_2 \cdot C_6H_5CH_2Cl$ .

It forms a light white powder, soluble in water and in dilute alcohol, insoluble in ether and in chloroform.

—J. O. B.

*“Geoside”: Guaiacol Valerianate.* Rieck. Pharm. Centralh. 1897, 38, 36.

THE valerianic ester of guaiacol—a yellowish oily liquid boiling between 245° and 265°, and having a specific gravity of 1.037—has been introduced into medicine under the name of “geoside.”—J. O. B.

*Guaiacol Phosphite and Phosphatol, Preparation of.* Ballard. Repert. de Pharm. 1897, [3], 9, 104.

ABOUT 50 grms. of caustic soda, dissolved in 90 per cent. alcohol, are added to 124 grms. of crystallised guaiacol, so that a clear yellowish solution is produced. Into this solution phosphorus trichloride is slowly introduced, by means of a tapped tubular funnel, until the solution is no longer alkaline to phenolphthalein; the sodium salts formed during the process are filtered off, the filtrate is distilled to remove the alcohol, and the residue extracted with absolute alcohol, which only removes the guaiacol phosphite; this alcoholic extract is evaporated on the water-bath and the phosphite crystallised out, purified by recrystallisation, drained on filter-paper, and dried over sulphuric acid. It forms a white, crystalline powder, with

a sharp, piquant, non-caustic taste, and slight odour. It melts at 77.5°. It is somewhat soluble in water, very soluble in strong alcohol, ether, chloroform, acetone, &c.; also in fatty oils.

By treating creosote by this method a mixture of the phosphorous esters of the various phenols present is obtained, which the author has termed “phosphatol.” It is a thick reddish-yellow liquid, with a slight odour of creosote and a warm taste; it boils at about 14°, but is not of definite composition.—J. O. B.

*Holocaine: A Cocaine Substitute.* E. Tauber. J. Pharm. Chim. 1897, 5, [7], 336. (See also this Journal, 1897, 555.)

THIS body, obtained by combining molecular proportions of phenacetin and paraphenetidine, is introduced as a substitute for cocaine for producing local anaesthesia. It is para-diethoxy-ethenylidiphenylamide.

It forms crystals melting at 121°, acting as a strong base, and forming with acids crystalline sparingly soluble salts. The hydrochloride crystallises in needles, soluble to the extent of 2 per cent. in cold water. A one per cent. solution is employed for therapeutic use.—J. O. B.

*Red Acaroid Resin of Xanthorrhoea Australis.* A. Tschirch and K. Hildebrand. Schweiz. Woch. für Chem. und Pharm. 1897, 35, 138.

THE crude resin consisted of small reddish-brown dusty pieces with a bright fracture, and contained about 10 per cent. of foreign matter, from which it was freed by solution in alcohol. It was then found to be soluble in ether, in ethyl, methyl, and amyl alcohols, in glacial acetic acid, potassium hydrate solution, acetone, and in phenol; while it was only sparingly soluble in benzene, toluene, chloroform, and carbon bisulphide. The resin was found to contain: (a) free paraeumaric acid, 1 per cent.; (b) as tannol esters—paraeumaric acid, 2 per cent., and benzoic acid, a trace; (c) an aldehyde—para-oxybenzaldehyde—0.6 per cent.; (d) erythroresinotannol, chiefly as paraeumaric ester, 85 per cent. Neither cinnamic acid in the free state nor its tannol ester, both of which the authors have found in yellow acaroid resin, were detected in this variety. The formula  $C_{40}H_{40}O_{10}$  was determined for erythroresinotannol.—J. O. B.

*Yellow Acaroid Resin of Xanthorrhoea Hastilis.* A. Tschirch and K. Hildebrand. Schweiz. Woch. für Chem. und Pharm. 1897, 35, 121.

AN examination of this resin has shown the following constituents:—(a) Paraeumaric acid, 4 per cent., and cinnamic acid, 0.5 per cent. in the free state; (b) as tannol esters—paraeumaric acid, 7 per cent.; cinnamic acid, 0.6 per cent.; (c) also styracin and phenylpropyl-cinnamate (?), 1 per cent.; para-oxybenzaldehyde and vanillin (?), 0.6 per cent.; lastly (d) xanthoresinotannol, 80 per cent. This last, combined with the paraeumaric acid in the form of ester, constitutes the bulk of the resin. The formula  $C_{43}H_{45}O_{10}$  is established for this body, which is therefore the homologue of erythroresinotannol,  $C_{40}H_{40}O_{10}$ .—J. O. B.

*Essence of Petit-Grain.* J. Passy. Bull. Soc. Chim. 1897, 519.

TIEMANN and Semmler (Ber. 25, 1180; this Journal, 1892, 706), and Bertram and Wahlbaum (J. Prakt. Chem. 49, 590), have pointed out that essence of petit-grain (*Citrus Bigaradia*) consists mainly of linalol, acetate of linalyl and a high-boiling sesquiterpene, but that these constituents do not sufficiently explain its odour. The author finds that it also contains geraniol, partly as the free alcohol and partly as its acetic ether. These contribute to a certain extent to the smell of oil of petit-grain, but there are, in addition, other hydroxy products which have not yet been identified.

—T. A. L.

*Castor Oil, Chemistry of.* H. Meyer. Pharm. Zeit. 42, 326.

ACCORDING to the author, the active constituents of castor oil are ricinoleic and ricinoleic acids. When pure castor

oil is treated with nitric acid, ricinelaic acid and ricinelaidin are formed, which, by themselves, are inactive. In solution or in the form of emulsion, they have, however, a marked aperient action. Dioxysearic acid, first discovered by Juillard, is also inert. By heating ricinoleic acid with glycerin in a current of carbonic acid gas to a temperature of  $280^{\circ}$ – $200^{\circ}$  C., an almost pure triglyceride is formed, which, in viscosity, taste, and aperient action, is exactly similar to the natural oil. It dissolves in an equal volume of alcohol and has a specific gravity between 0.959 and 0.984. This pure triglyceride may be regarded as synthetic castor oil.—J. O. B.

*Production of Camphenol from Camphor.* J. E. Marsh and J. A. Gardner. *Proc. Chem. Soc.* 1897, [181], 137.

The authors have described (*Trans.* 1897, 71, 285) the production of an isomeride of camphor—camphenol. This substance was obtained by the action of strong sulphuric acid on chlorocamphene,  $C_{10}H_{15}Cl$ . Camphenol is produced by the action of the same reagent on camphenyl dichloride,  $C_{10}H_{13}Cl_2$ , which is the immediate product of the action of phosphorus pentachloride on camphor. The same camphenol is apparently produced from both the isomerides of the formula  $C_{10}H_{15}Cl_2$ , obtained from ordinary camphor, and a satisfactory yield is obtained in both cases. The action of strong sulphuric acid on other chloro-derivatives of terpenes has been examined. In particular, turpentine dihydrochloride behaves in a manner very similar to the camphenol derivative, but the nature of the product of the reaction has not yet been determined.

*Essential Oils, A New Product for Reducing.* Extract from the British Pharmaceutical Journal, through U.S. Cons. Reps., June 1897, 213.

This is a volatile oil offered for sale on the London market. It has a "fancy" name, is stated to be of vegetable origin, and to be specially manufactured for the purpose of reducing essential oils. It is also said to combine perfectly with both Sicilian and French essential oils. With the view of ascertaining its properties, a pint sample of the oil was obtained and submitted to analysis. The following results were arrived at: Specific gravity at  $15.5^{\circ}$  C., 0.869; optical rotatory power in tube at 200 mm.,  $59^{\circ}$ ; flashing point (Abel's method),  $100^{\circ}$  F.; solubility in three volumes of alcohol of specific gravity 0.82, fairly soluble; residue on evaporation, trace.

*Fractional Distillation.*—Percentage yielded between  $155^{\circ}$  and  $160^{\circ}$  F., 3.5;  $160^{\circ}$  and  $165^{\circ}$  F., 55;  $165^{\circ}$  and  $170^{\circ}$  F., 21;  $170^{\circ}$  and  $180^{\circ}$  F., 9; above  $180^{\circ}$ , 8.5.

There was no aldehyde present, and only a trace of the presence of ester could be discovered when the oil was subjected to saponification.

From the results obtained, this oil appears to have the characters of a leopinene, such as is obtained from *Pinus sylvestris*, *Abies excelsa*, *Pinus maritima*, &c. The oil has a delicate odour not unlike that of some of the commercial varieties of pine oils, and experiment shows that considerable proportions of it may be mixed with oils of lemon and bergamot without the presence of the adulterant being detectable to smell or taste. Such detection would also be difficult by any of the ordinary physical tests (specific gravity, rotation, &c.) which are applied to essential oils; and the importance of having standards, such as the percentage of citral in lemon oil and of linalool acetate in bergamot, is emphasised by a consideration of the impunity with which adulteration can otherwise be conducted.

## PATENTS.

*Vanillin, Process for the Manufacture of, from Isoeugenol and Eugenol.* H. Muray, London. From Haarmann and Reimer, Holzminnen, Germany. Eng. Pat. 14,928, July 6, 1896.

VANILLIN is prepared from isoeugenol by treating the boiling alkaline solution with peroxides, such as sodium peroxide, or other bodies giving off oxygen in the presence of excess of alkali; on cooling and acidulating, vanillin may be washed out with ether. Vanillin may be prepared direct from eugenol by this method by first converting it into isoeugenol, according to De Laire's Eng. Pat. 17,547 of 1890 (this Journal, 1891, 854), and then oxidising the latter as described above.—J. O. B.

*Thyroid Gland, Process for the Production of the Active Constituents of.* O. Muray, London. Eng. Pat. 16,137, July 21, 1896.

THYROID glands are reduced to a finely-divided state by chopping, and extracted with a solution of sodium chloride (0.75 per cent.), in which menstruum the active principles are soluble; after separation from the inert matter by mechanical means, the solution is treated with a 10 per cent. solution of tannin, which completely precipitates the active principles. The precipitate is then dried and used as a medicament. It contains about 0.4 per cent. of iodine.—J. O. B.

*Vanillin, Impts. in the Manufacture of.* G. B. Ellis, London. From La Société Chimique des Usines du Rhône, anciennement G. P. Monnet et Cartier, Lyons. Eng. Pat. 16,239, July 22, 1896.

THE process consists, first, in the preparation of carboxylic esters, especially the methyl carboxyl ester of protocatechuic acid, by the action of the methyl or other ester of chloroformic acid upon the potassium or sodium salt of protocatechuic aldehyde. The ester thus produced, which melts at  $98$ – $99^{\circ}$  C., is then methylated by means of alcoholic potash and dimethyl sulphate at ordinary temperatures, at 1 finally hydrolysed by means of dilute mineral acids. Upon distilling off the alcohol, vanillin is left in the residue, from which it is extracted with ether. By this method, the simultaneous formation of a large amount of isovanillin is avoided.—J. O. B.

*Drying Substances [containing Aromatic Oils], Improved Process for.* H. Humbser, Fürth, Bavaria. Eng. Pat. 6065, March, 8, 1897.

See under XVII., page 627.

## XXI.—PHOTOGRAPHY.

### PATENT.

*Photographs with Coloured Effects, Impts. in, and in Methods of Producing the Same.* G. J. Sershall, Birmingham. Eng. Pat. 3121, Feb. 5, 1897.

THE photograph with coloured effects consists of a transparent front, preferably of celluloid, carrying a photographic film to form the keystone of the coloured picture, and a colour-printed backing of paper, cardboard, or the like, developed by any well-known mechanical process of colour printing; the two being fixed permanently together with the film side of the transparent front and the coloured surface of the backing adjacent to each other. A number of single photographs may be thus arranged in a sheet, which may be registered and cut out.

In practice, a negative is first taken of any number of photographs. From this a sheet of carbon tissue is taken, which is developed upon a sheet of transparent celluloid, ivory, gelatin, or tale, the result being a number of pictures on one side of the transparent sheet. A sheet of transparent gelatin is then fixed to this sheet with registering pins, and a tracing taken with a sharp-pointed instrument of the outlines of the pictures and of those parts to be developed by colouring matter. The tracing is removed, treated with powdered blacklead, and rubbings

down, or impressions are taken from it upon stones sufficient to comprehend all the colours required in the backings. The traced parts of the stones are then drawn and coloured, and the backings are printed from them in the ordinary way. The transparent films and the coloured backings are then pressed together with any transparent adhesive material, and thus form the coloured photograph.

—J. O. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Sodium Acetylide and Carbide, Thermal Properties of.* C. Matignon. *Comptes Rend.* 1897, **124**, 1026—1028.

THE heats of formation of the above compounds are as under:—

Al—O—

Sodium acetylide and carbide are therefore endothermic compounds. They are decomposed, with separation of carbon, when incautiously heated; and furnish, in combination with oxidising agents, highly explosive mixtures, most of which are very sensitive to friction.—H. T. P.

*Sodium Acetylide and Carbide, The Preparation of.* C. Matignon. *Comptes Rend.* 1897, **124**, 775—777.

THE following processes are based on the observation that when fused sodium acts on acetylene, the sole product at temperatures below 190° C. is sodium acetylide, whilst only sodium carbide is formed at temperatures exceeding 210°—220° C.:—

*Sodium Acetylide, NaHC<sub>2</sub>.*—Pure, dry acetylene is passed into a large flask containing metallic sodium, heat being applied by means of an oil-bath maintained at 180° C. The contents of the flask must be frequently agitated, in order to break up the crust of acetylide and to expose a fresh surface of sodium to the gas; and the action should be allowed to continue for some time after the mass has lost all metallic appearance, in order that every trace of sodium may be converted into acetylide.

*Sodium Carbide.*—The method is, in general, the same as above; but the oil-bath must be rapidly heated to 220° C., and maintained at 220°—230° C. Any acetylide formed below 200° C. is again decomposed at the higher temperature, either under the influence of heat alone, or by the action of the excess of sodium, into carbide. A white, very pure carbide is obtained by this process.—H. T. P.

## PATENTS.

*Fuse or Quick-match, An Improved Safety.* C. Lamm, Blackburn. *Eug. Pat.* 14,329, June 29, 1896.

Two kinds of fuse are described: one consisting of a twist or core of nitrocellulose, or mixed nitrocellulose and cellulose, which has been impregnated with a solution of nitrate and chlorate of potassium, containing, in addition, either yellow prussiate, picrate, or carbonate of potassium. This core is then immersed in a bath of ether-alcohol, nitrobenzene, or other suitable solvent, until the nitrocellulose is gelatinised. After drying, the twist may be employed directly as a fuse, or can be insulated. The other consists of a core of cellulose, which, after boiling in a solution of chlorate and ferrocyanide of potassium, and drying, is surrounded with jute yarn and made waterproof.

—W. M.

*Explosives, Impts. in or relating to.* M. Van Look, Cologne. *Eug. Pat.* 6161, March 11, 1897.

THE inventor proposes to make an explosive by charging a cartridge or shell with calcium carbide and water held in separate receptacles. The explosion is brought about by causing the fracture of the water vessel, when the reaction between the water and carbide generates gas.—W. M.

*Explosive Compounds, Impts. in the Manufacture of.* G. B. Ellis, London. From La Société Chimique des Usines du Rhône, Lyons, France. *Eug. Pat.* 15,022, July 7, 1896.

FINELY ground coke is treated with desulphurised tar which has been neutralised by the addition of magnesium carbonate and then dried and ground so as to form a pulverulent carbonaceous material, which is then mixed by sifting with finely ground chlorate or perchlorate of potassium. A still safer explosive can be made by previously treating the chlorate with a dilute solution of shellac or purified tar. Suitable proportions are: "80 parts of chlorate or perchlorate of potassium, 3½—7½ parts of tar, 12—14 parts of charcoal or coke, ½—1 part of carbonate of magnesia or lime."—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Polariscope, Yellow Sodium Light for the.* F. Dupont. *Bull. Assoc. Chim.* **14**, 1041.

DIFFICULTIES are often encountered in using yellow light for polarimetric observations. The author finds that a mixture of sodium chloride and tribasic sodium phosphate, melted together in approximately molecular proportions, answers perfectly. This mixture melts more easily than common salt, never decrepitates, and imparts to the flame a brilliant yellow colour, so that observations thus become extremely easy and precise.—L. J. de W.

*Gas-Analysis Apparatus.* O. Eleier. *Ber.* 1897, [10], 1210—1211.

IN order to obviate the inclusion of air in connecting the author's pipettes (this Journal, 1896, 616) with the burette figured in this Journal, 1896, 294, which see, it is proposed to replace the tap *a* (Fig. 1, *loc. cit.*) by a two-way cock, which will connect a horizontal capillary on the tap with the interior of the burette or with a cup above the tap. The pipette is connected to this horizontal capillary, and the absorbent is made to flow into the tap before connection is made between burette and pipette; after the absorption, the liquid is again led into the tap; this may be accomplished by means of a screw clip on the rubber connection. If mercury be used, the three-way cock *b* (*loc. cit.*) may be omitted and the capacity of the burette reduced to 25 c.c. (the length remaining the same) without loss of accuracy. The size of the pipettes may be diminished in the same degree.

In exact gas analysis the use of such a two-way tap to effect connection between burette and pipette without the introduction of air, considerably simplifies the apparatus. In the Hempel apparatus the mercury bath may be dispensed with, the measuring bulb fixed, and solidly connected with the water jacket and pressure tube.—A. C. W.

## PATENT.

*A Photometer for Automatically Measuring and Registering the Intensity of the Light of a Gas Flame, and Apparatus therefor.* W. and B. Cowan, Ltd., Westminster. From C. V. L. Martenson, Rio de Janeiro. *Eug. Pat.* 9041, April 9, 1897.

THE principle on which this invention is based is that if a gas flame under constant pressure be allowed to impinge upon an inclined surface, given horizontal movement in such a direction that a line upon it, perpendicular to a line of greater incline, is maintained at a certain level during the motion on or over a vertical line passing up through the centre of the flame, the smoke deposited by the flame will produce a characteristic impress. The lower part of the impress will rise or fall according to the greater or less illuminating power of the gas, the width of the impress varying in direct proportion to the illuminating power.

The apparatus is constructed within a case, to shelter the flame from all draughts. The flame impinges upon a cone of incombustible material mounted on a vertical axis, to which a uniform rotatory motion is imparted by suitable mechanism. The rate may be one revolution in 24 hours,

or one per week, the cone having its surface marked off into hours. There is thus automatically obtained a diagram recording the variations in the quality of the gas. The sides of the cone may be either straight, slightly concave, or slightly convex; or it may be replaced by a cylinder mounted on an oblique axis. The angle of the oblique axis is controllable by means of a sliding block, which can be operated by a screw outside the apparatus.

The four claims embrace the general method of automatically testing the gas, and various details of the constructions shown.—H. B.

## INORGANIC CHEMISTRY.—QUALITATIVE.

*Lead Chromate in Coloured Wrappers, Rapid Method of Detecting.* J. Wolff. *Annal. Chim. Analyt.* 1897, 2, 103.

Lead chromate is frequently employed on the Continent as a pigment for the yellow paper which is used as wrappers for chocolate and other sweetmeats. Its use for this purpose is obviously objectionable.

The presence of the lead pigment is readily shown as follows:—A square of about 5 cm. of the suspected paper is placed, without folding, in a small flat-bottomed capsule, and moistened with alcohol, 90 per cent.; when it is thoroughly saturated, the excess of alcohol is drained off, and a few drops of nitric acid are allowed to flow over the surface of the paper. If chromate be present, the characteristic odour of aldehyde will be given off, and the paper will be coloured green. The nitrate of lead formed during the reaction is dissolved in 10 or 15 c.c. of water, and if too great an excess of acid has not been used, the characteristic precipitate of lead iodide may be obtained at once from the decanted solution. Green papers, coloured with a mixture of lead chromate and Prussian blue, may be tested in a similar manner. The author regards zinc chromate as inoffensive as a pigment for these articles.

—J. O. B.

## INORGANIC CHEMISTRY.— QUANTITATIVE.

*Illuminating Gas, Determination of Oxygen in.* O. Pfeiffer. *J. für Gasbeleucht.* 1897, 40, 354—357.

In gas analyses carried out over water, the error of observation is not less than 0.2 per cent, and therefore the ordinary determinations of oxygen in coal-gas are of doubtful value. When oxide of iron is continuously reoxidized *in situ*, it becomes necessary to have a better method of ascertaining the amount of oxygen or air in the gas. Several likely schemes having been tried and found worthless, a colorimetric method was finally found satisfactory.

100 c.c. of the gas to be examined are taken in a Bunte burette, and the water within is then drawn out by suction until it only fills the capillary of the lower cock. 5 c.c. of solution of caustic potash (1 to 2) is then passed up through this cock. The funnel at the top of the burette having been emptied, 0.2 gm. of pyrogallol is put in it and 2 c.c. of water added. The solution thus formed is admitted to the burette, with the exception of one drop, which seals the capillary. The burette is agitated for 5 minutes, and water is then admitted through the lower cock until it reaches a predetermined mark—e.g., the zero—on the burette. After the lapse of two minutes, the colour of the liquid in the burette is compared with that produced in the same volume of water in a wide test glass by the addition, drop by drop, of a caramel solution of known strength. The number of drops required to bring the water to the same colour as the liquid in the burette, corresponds to a certain amount of air. This relation is ascertained empirically.

The caramel solution is made by dissolving 30 grms. of cane sugar in a litre of boiling water, adding thereto 30 c.c. of sulphuric acid (1 to 3), and boiling for  $\frac{1}{2}$  hour. Then 85 c.c. of solution of caustic soda (sp. gr. 1.30) are added gradually, and boiling is continued for another  $\frac{1}{2}$  hour. If kept in the dark, the solution thus made does not change in colour. It corresponds in tone to the galloflavin produced by the pyrogallol reaction in the burette. Samples of gas

containing known percentages of air are then treated precisely as just described, and the number of drops in the caramel solution which give the requisite colour in each case is ascertained. From values so found, a curve is drawn, from which may be deduced the percentage of air corresponding to any number of drops of the caramel solution.

The oxygen in the small quantity of water admitted to the burette may generally be ignored, as its amount is small and nearly constant for all the tests. In some cases—such as when the presence of oxygen merely is in question—it is, however, desirable to use water free from oxygen. The small quantity of water in a test glass may be deoxygenated by boiling, but even prolonged boiling of larger quantities fails to remove entirely the oxygen. Phosphorus removes the oxygen, but imparts its odour to the water. The water for the purpose is best deoxygenated by contact with zinc, of which the activity has been enhanced by immersion in water containing a few drops of solution of copper sulphate. After washing, the zinc is put in a Woulff's bottle, which is filled with water saturated with coal-gas. After bubbles of gas and air have been liberated, the water will in a few hours be free from oxygen, and may be drawn off for use through the longer limb, while more water is admitted to the bottle through the shorter limb. A continuous supply of water free from oxygen may be thus obtained.—J. A. B.

*Chlorine and Bromine, Separation and Estimation of.* H. Baubigny and P. Rivals. *Comptes Rend.* 124, 859—862.

Potassium permanganate decomposes cupric bromide in the cold with liberation of bromine, while it does not act on cupric chloride. To apply this in analysis, the mixed alkali chloride and bromide (0.2 to 0.4 gm.) are carefully weighed, dissolved in water with 4–8 grms. of copper sulphate crystals, and to the cold solution is added 0.35 to 0.40 gm. of potassium permanganate. After solution, the whole is evaporated to dryness in a wide, shallow vessel, *in vacuo*, over caustic potash at the ordinary temperature. After 24 hours the residue is taken up with water, sulphurous acid added to reduce remaining permanganate or manganese dioxide, and the chlorine precipitated by silver nitrate containing excess of nitric acid. The mode of calculation is obvious.

Results of test experiments with known quantities of alkali chlorides and bromides are given, proving the accuracy of the method. Where chloride alone was used, the evaporation with permanganate was twice repeated, to exaggerate the possibility of decomposition of the chloride.

Substituting aluminium sulphate for copper sulphate in the method as described, a considerable loss of chlorine always takes place.—J. T. D.

*Cyanogen, Notes on the Estimation of, by Silver Nitrate.* [Potassium Iodide and Ammonia as Indicators.] W. J. Sharwood. *J. Amer. Chem. Soc.* 1897, 19, [5], 400—434.

5 c.c. of ordinary ammonia (Liq. Ammon.) and 2 c.c. of a 5 per cent. potassium iodide solution are added to 25–100 c.c. of the solution in which cyanogen is to be determined, and the liquid is titrated with standard silver nitrate (1.305 grms. of cryst.  $\text{AgNO}_3$  in 100 c.c. of water) till a faint permanent cloud forms. For rapid approximate determinations, 10 c.c. of the sample should be taken and 1 c.c. each of ammonia and iodide solution. If sufficient ammonia be already present in the solution, no more should be added; if a large amount be present, a larger quantity of iodide is added to reduce the error. A larger addition of iodide will also partly remove the error due to the presence of thiosulphates. If sulphides be present in small amount, the potassium iodide is replaced by 5 or 10 c.c. of a solution of 0.5 gm. of iodine and 2–3 grms. of potassium iodide in 100 c.c. of water, the mixture allowed to stand five minutes, and, after addition of ammonia, titrated. The result is corrected by adding the difference between two parallel tests (1) on some pure dilute potassium cyanide solution, and (2) on an equal amount of potassium cyanide plus 5 or 10 c.c. of the iodine solution. If the amount of sulphide be large, or if other reducing agents be present, twice the usual volume of solution is taken, soda ash then sodium plumbite in very

slight excess added, the mixture well shaken, made up to a definite volume, filtered, and one-half of the clear filtrate used for titration, rejecting the first few c.c. filtered. In presence of zinc, a considerable excess of caustic soda or potash is added before titration and the final precipitate tested with more alkali; if it dissolves, more alkali is added and the titration continued; if insoluble, the cyanogen found represents that contained in both potassium zinc cyanide and free potassium cyanide. The free potassium cyanide may be rapidly and roughly determined by adding a few drops of a 5 per cent. solution of potassium ferrocyanide and titrating with silver nitrate until a faint flocculent precipitate forms (using *a* c.c.), then adding ammonia, potassium iodide, and soda, and titrating for total cyanogen (using *b* c.c. altogether). Then, according to Bettel,  $a - 0.086(b - a)$  represents the cyanogen as free cyanide, and  $(b - a) \div 0.921$  gives the cyanogen present as double cyanide, if free alkali were originally absent; the error and correction is increased if free alkali were originally present, and varies slightly with the time occupied in titrating. The free cyanide may be more accurately determined by acidulating a portion of the solution with hydrochloric acid, evaporating off the hydrocyanic acid, estimating zinc by standard ferrocyanide, and subtracting four equivalents of potassium cyanide for each atom of zinc found.

In presence of copper, the cyanogen present as double copper cyanide is obtained by estimating the copper colorimetrically with ammonia, after expelling hydrocyanic acid with nitric or sulphuric acid, and allowing 3—4 equivalents of cyanogen for each atom of copper. In presence of calcium, magnesium, or manganese, ammonium chloride is added before titration, and in presence of aluminium or lead, caustic soda. The quantities of gold, silver, and other interfering substances present, are usually too small to appreciably affect the results.

With impure solutions, the results obtained by this method are more accurate than those given by the ordinary Liebig method; with pure solutions, the results are practically identical, but the end reaction is sharper and an estimation can be more rapidly carried out. 170 grms. of  $\text{AgNO}_3$  correspond to 52 grms. of cyanogen.—A. S.

[*Alkali Chlorides in Presence of Iodides, &c.*] *Quantitative Analysis by Means of the Telephone, A Simple Method for.* H. Erdmann. Ber. 1897, [10], 1175—1182.

NORMAL solutions of very similar electrolytes have approximately the same conductivity. Hence, in solutions of equal percentage strength, the resistance is nearly proportional to the molecular weight of the dissolved substance. For example, Bouty found the resistances of 5 per cent. solutions of potassium chloride, bromide, and iodide to be in the ratio 1:1.47:2.13, whilst the ratio of the molecular weights of these salts is 1:1.60:2.23. In consequence of the great differences in the conductivities of such solutions, the amount of potassium chloride contained in a mixture with the bromide or iodide may be quantitatively determined. For purposes in which absolute measures of conductivity are not required, but only comparative values, the physical method of determining conductivities may be greatly simplified for the analytical process. The apparatus consists of two cylindrical vessels 9 cm. high and 4 cm. in diameter, in which are contained the electrodes—platinum plates covered with platinum black (see "Physico-chemical Measurements," Ostwald; translated by McGowan), placed about 2 cm. apart. The two cells are contained in a covered vessel full of water and provided with a stirrer. The current is obtained from a small induction coil worked through a resistance of 0.6—0.7 ohm by a Bunsen's or Grove's cell. The ends of a Wheatstone's bridge are connected to the cells and to the induction coil; the telephone is placed on the wire connecting the junction of the two cells with the sliding contact on the bridge wire.

One per cent. solutions of salts or mixtures are employed. These should be made up in graduated flasks of Jena glass which have been well boiled with water. The water employed for the solutions need not be distilled through a condenser with a tin tube. For the details of the process, the analysis

of a mixture of potassium chloride and bromide is given. 10 grms. of the pure chloride are dissolved in water and the solution made up to 1 litre; the two cells and electrodes are washed with this solution, 50 c.c. is then placed in each cell, the circuit closed, and the sliding contact adjusted until the minimum of sound is perceptible in the telephone. After a few minutes, to allow equalisation of temperature, the position is constant; successive readings will not differ by more than 0.2 mm.; the mean of two or three readings is taken. One cell is now emptied, washed out with 1 per cent. potassium bromide solution, filled with 50 c.c. of this solution, and readings taken as before. In the same way this cell is filled with 1 per cent. solutions of unknown composition and readings taken. If *A* be the reading in millimetres on the scale 1 m. long, *r* and *r'* the resistances in the two cells, then the ratio of these resistances—

$$r = \frac{r'}{\rho} = \frac{A}{1000 - A}$$

The following results were obtained with solutions of known composition:—

KCl : KBr.	A.	<i>r</i> .	KBr taken.	KBr found.
100 : 0	651.02	1.86518	Per Cent.	Per Cent.
99 : 1	650.61	1.86180	0.00	0.00
1 : 1	606.96	1.54472	1.00	0.53
2 : 3	507.32	1.48324	50.00	50.31
1 : 9	563.27	1.28962	80.00	59.96
0 : 100	551.24	1.22820	100.00	90.38
				..

The results of determinations of potassium iodide in mixtures with the chloride were more exact. This method of analysis might with advantage be used where a large number of determinations have to be carried out in a short time.—A. C. W.

*Magnesium Sulphate, An Adulteration of.* P. A. Lawanna. Boll. Chim. Farm. 36, 198; Chem. Central-Bl., 1897, 1100.

The author has observed a case of adulteration of magnesium sulphate with zinc sulphate; this may be detected by the addition to an aqueous solution of the salt, of one drop of potassium ferri-cyanide solution, which causes a brownish-yellow precipitate.—A. C. W.

*Silicic and Tungstic Acids, Note on the Separation of.* J. S. de Benneville. J. Amer. Chem. Soc. 1897, 19, 377—379.

THIS note calls further attention to the fact already pointed out by several observers, that in the method of determining tungsten by obtaining a mixed residue of tungstic acid and silica and dissolving the tungstic acid out of this by ammonia, a part of the silica is also dissolved by the ammonia. On evaporating the ammoniacal solution to dryness, igniting, and digesting with hydrofluoric acid, with or without the addition of a few drops of sulphuric acid, the silica can be expelled and the tungstic acid obtained pure. In determining silicon in tungsten alloys, it is also important to bear in mind the fact that a part of the silica is dissolved by ammonia. A table is given which shows that in a ferro-manganese containing nearly 7 per cent. of tungsten, several evaporations with hydrofluoric acid were sometimes necessary to remove the whole of the silica from the mixed oxides of silicon and tungsten.—H. S. P.

*Silica, Determination of, in Blast-Furnace Slag.* G. H. Mecker. J. Amer. Chem. Soc. 1897, 19, 370—374.

THE author advocates the use of sulphuric acid for decomposing blast-furnace slags in the determination of the silica contained in them, in preference to hydrochloric acid, because he finds that slags generally, and especially some special kinds of slag containing spinel (magnesium aluminate) and certain complex titanium compounds, are more perfectly and rapidly decomposed, and further, that the silica is more quickly dehydrated and rendered insoluble by sulphuric acid than by hydrochloric acid.

This method of procedure is as follows:—"one-half gram of finely ground slag is placed in a four-inch evaporating basin, covered with cold water (about 3 c.c.), and stirred to break up lumps. To the contents of the basin 10 c.c. of concentrated hydrochloric acid are then added, stirring vigorously to prevent sticking to the bottom.

"As soon as the slag seems dissolved as much as it will, and before it has set to a jelly, pour in 40 c.c. of sulphuric acid (one volume concentrated acid to one volume water), stir well, wash off stirring rod, and then cover solution with a funnel. The funnel should have fused edges and be of such size as to rest upon the sloping inside of the evaporating basin and set down above the solution.

"Place the evaporating basin on a wire gauze and boil rapidly until fumes of sulphur trioxide begin to come from under the edges of the funnel. Cool, dilute somewhat, and clean off the funnel. Add about 10 c.c. of hydrochloric acid and dilute until the basin is as full as it can be conveniently. Cover with watch-glass and boil gently for one minute. Filter at the vacuum pump. Wash five times with hot hydrochloric acid (sp. gr. 1.10) and five times with hot water. Burn and weigh. The silica is remarkably pure. On 'chilled' slags the impurities are from 0.05 to 0.20 per cent."

A table of results is given comparing this method with a method consisting of twice evaporating the slag to dryness with hydrochloric acid at a temperature not exceeding 120°C., and finally purifying the silica with hydrofluoric acid, which shows a very good agreement between the two methods for ordinary slags; but in the case of a slag containing spinel and other compounds not decomposed by hydrochloric acid, the determination of the silica by the hydrochloric acid method was about 1½ per cent. too high.

The author also refers to the known fact that slags containing spinel are only decomposed with great difficulty by fusion with sodium carbonate, and points out that his method, owing to the readiness with which it decomposes such slags, has therefore a distinct advantage.—H. S. P.

*Lead, Volumetric Determination of.* J. H. Wainwright. J. Amer. Chem. Soc. 1897, 19, 389—393.

THIS is a modification of the method of volumetric determination of lead by a standard solution of potassium bichromate, using as an indicator spots of silver nitrate. The method must be carried out exactly under the conditions specified, which is described in the case of litharge as follows:—"1.00 to 1.25 grms. is dissolved in 10 to 15 c.c. of nitric acid (sp. gr. 1.20), the solution neutralised with ammonia in excess, and a considerable excess of acetic acid added. It is then boiled, and the standard solution of potassium bichromate run into the boiling liquid in sufficient quantity to precipitate all the lead. The liquid is then again brought to the boil, and the addition of bichromate solution then continued at the rate of about half a c.c. at a time, stirring well between each addition, until the lead bichromate settles suddenly to the bottom, leaving the liquid clear. This occurs usually about 1 c.c. from the final quantity of bichromate required. The addition is then continued drop by drop, testing the clear supernatant liquid between each addition by mixing a few drops of it on a white porcelain plate with a drop or two of silver nitrate until a distinct red colour of silver chromate appears.

The chief points to be observed are:

1. The solution of the lead salt should be as concentrated as possible, and decidedly acid with acetic acid.

2. It should be free from other metals, especially such as may exist in the lower forms of oxidation. Antimony and tin must be oxidised by repeated evaporations with fuming nitric acid. Bismuth must also be absent.

3. The solution of lead must be kept as near the boiling point as possible.

4. The strength of the bichromate solution should be such that 1 c.c. approximately equals 0.01 gram of lead. It may be standardised with pure lead or a pure "white lead," in which the lead has been accurately determined gravimetrically.

5. The solution of silver nitrate should be dilute—not more than 2 to 3 per cent.

Results by this method agree to within 0.2 to 0.3 per cent. with the gravimetric, in which the lead is weighed as lead sulphate.—H. S. P.

*Lead, Determination of, in Lead Ores.* R. K. Meade. J. Amer. Chem. Soc. 1897, 19, 374—377.

ONE gram of the ore, if rich—more, if poor—is treated in a platinum dish covered by a watch-glass, with 10 to 50 c.c. of a mixture of one part of sulphuric acid (1.84 sp. gr.) and three parts of nitric acid (1.12 sp. gr.). Heat is applied on a water bath or hot-plate until the action of the acids on the ore has apparently ceased. The watch-glass is rinsed and removed, and 10 to 15 c.c. of hydrofluoric acid are added, and the solution evaporated until fumes of sulphuric acid come off. The liquid is then cooled, diluted to about 100 c.c. with water, digested until all the soluble salts are dissolved, the precipitate of lead sulphate filtered and washed, first with a 2 per cent. solution of sulphuric acid and then with alcohol, after which it is dried, separated from the paper, ignited in the usual way, and weighed.

The method is, of course, not applicable in presence of barium, strontium, and calcium, or of metals that are converted into insoluble oxides by nitric acid.—H. S. P.

*Lead, Estimation of, in Slags and other By-Products.* D. J. Williams. Chem. and Metall. Soc. of S. Africa, Proc. of Meeting, May 15, 1897, 11—14.

THREE volumetric methods for the rapid estimation of lead in slags are compared with a standard gravimetric method. In every case the ore was finely crushed in an agate mortar. In the first case, 1 gram of the sample was boiled with 5 c.c. of HCl and 5 c.c. of HNO<sub>3</sub>, cooled, and then evaporated with 15 c.c. of H<sub>2</sub>SO<sub>4</sub>. When sulphuric acid fumes were evolved, the liquid was diluted, filtered, and washed as usual. The precipitate was then transferred to a beaker and dissolved in ammonium chloride, the residue being extracted with 200 c.c. of strong caustic soda, and the last traces of lead so removed, precipitated with sulphuric acid, and transferred to the beaker containing the bulk of the lead. A few c.c. of nitric acid were now added, then a few drops of phenolphthalein and an excess of caustic soda, whereupon the lead was precipitated with pure oxalic acid. After filtering and washing with cold water, the precipitate was rinsed into a flask containing 70 c.c. of hot water; a few c.c. of strong sulphuric acid were added, and the liberated oxalic acid was determined by standard permanganate solution. Each determination required 45 minutes, and the mean of 10 tests showed an error of 0.4 per cent.; bismuth and antimony are interfering metals. In the second process, the lead was obtained as sulphate, as before, and this was then transferred to a beaker and mixed with 50 c.c. of a saturated ammonium carbonate solution. After boiling for a few minutes, filtering, and washing with hot water, the precipitate was dissolved in acetic acid, and titrated with standard ferrocyanide solution. Such a determination may be made in an hour, and may be correct to within 0.7 per cent. The third process is that described by Alexander (see this Journal, 1893, 12, 376); it requires only 25 minutes, and should be correct to within 0.15 per cent. The details of the method as used by the author are as follow:—"A weighed quantity is heated on the hot plate with 20 c.c. of H<sub>2</sub>SO<sub>4</sub> until decomposed. After cooling, 20—30 c.c. of HNO<sub>3</sub> are added; the mixture is now heated until fumes of sulphuric acid are evolved. After cooling, it is diluted to about 75 c.c. with cold water, and boiled to dissolve any sulphates. The liquid is filtered, leaving as much as possible of the precipitate in the beaker, and washed with dilute sulphuric acid. The precipitate is then dissolved in ammonium acetate solution, and made up to ½ or ¾ litre, and titrated with standard ammonium molybdate solution, with a freshly made solution of tannin as an indicator, using drops of the liquids on a porcelain plate for the test. The solution need not contain free acetic acid, and ammonium chloride may be substituted for the acetate. Although arsenic and antimony do not interfere with this method, large quantities of lime may prove prejudicial.—W. G. M.

*Nickel from Cobalt and Iron, Cobalt from Aluminium; Separation of.* E. Piñerúa. *Comptes Rend.* 124, 862—863.

NICKEL chloride and aluminium chloride are insoluble in ether saturated at a low temperature with hydrochloric acid, while the chlorides of cobalt and of iron dissolve in it readily.

The mixed chlorides of nickel, cobalt, and iron are dissolved in as little water as possible, a mixture (about 20 c.c. to 0.3 gm. of the chlorides) of equal volumes of ether and fuming hydrochloric acid is added, and the whole, in a bath of salt and ice, saturated with hydrochloric acid gas. The nickel separates as a heavy yellow crystalline precipitate, which is washed, first by decantation, and then on the filter, with ether saturated with hydrochloric acid, and then converted into one of the ordinary forms in which nickel is weighed. Cobalt remaining in solution gives a deep blue colour to the liquid, iron a green; small quantities of iron perceptibly change the blue of the cobalt solution; hence this method affords a ready qualitative test for the other metals in reputedly pure salts of cobalt or of nickel.

Where much iron is associated with nickel, the precipitate retains traces of iron, and should therefore, after washing, be redissolved and reprecipitated.

Exactly the same method is pursued to separate cobalt from aluminium. In all these cases the method gives very exact results.—J. T. D.

*Phosphor Bronze, Phosphor Copper, Phosphor Tin, &c.; Analysis of.* M. Wickhorst. *J. Amer. Chem. Soc.* 1897, 19, [5], 396—398.

*Estimation of Phosphorus alone.*—1 gm. of the sample is treated with 20 c.c. of aqua regia (15 of  $\text{HNO}_3$  to 5 of  $\text{HCl}$ ) and the mixture warmed. When the reaction is complete, water is added, then excess of ammonia, and the whole made up to 200 c.c. The copper, lead, &c. are precipitated by sulphuretted hydrogen, the sulphides filtered off, and the phosphorus precipitated in 100 c.c. of the filtrate by adding 10 c.c. of magnesia mixture and ammonia. After standing a few hours, the precipitate is filtered off into a Gooch crucible, washed with dilute ammonia containing a little ammonium sulphide, ignited, and weighed as magnesium pyrophosphate. If a very accurate determination be required, the precipitate is dissolved in dilute hydrochloric acid and reprecipitated with magnesia mixture and ammonia.

*Complete Analysis.*—0.5 gm. of the sample is treated with 5 c.c. of strong nitric acid, and the mixture heated until the reaction is complete. The residue is well rubbed with a glass rod, and after adding a little water, the insoluble matter is filtered off on to a small filter and washed with water containing a little nitric acid. The moist filter is placed in a weighed porcelain crucible, and the whole heated, gently at first, and finally with the blow-pipe. The residue consists of stannic oxide and nearly all the phosphorus as pentoxide. The latter is estimated by fusing with 0.5 gm. of  $\text{Na}_2\text{CO}_3$  and 1 gm. of S, keeping the lid on the crucible. Heat is applied until the excess of sulphur is driven off, after which the mass is allowed to cool, dissolved in water, excess of ammonia and 1 gm. of ammonium chloride added, and the phosphorus precipitated with magnesia mixture. The precipitate is collected on a Gooch filter, washed with dilute ammonia containing a little ammonium sulphide, dissolved in dilute hydrochloric acid, reprecipitated with ammonia and magnesia mixture, filtered, ignited, and weighed. The difference between the weights of phosphorus (calculated to pentoxide) and of the total insoluble residue gives the amount of stannic oxide, from which the percentage of tin can be calculated. A small amount of phosphorus is dissolved by the nitric acid treatment, and this is determined by weighing out a duplicate sample, treating in the same way as above, precipitating the filtrate by molybdate solution, and determining the phosphorus by one of the usual methods.

The filtrate from the insoluble tin oxide and phosphorus pentoxide is just neutralised with ammonia, 5 c.c. of nitric acid added, and the mixture made up to about 150 c.c. with water in a large platinum dish. A piece of platinum foil

is suspended in the solution and an electric current passed through, so as to precipitate the lead as dioxide on the dish and the copper as metal on the foil. When all the copper is precipitated—ascertained by testing a drop of the solution with ammonia—the liquid is siphoned off from the precipitates, fresh water being poured in, until the liquid is nearly free from acid. The precipitates are finally well washed with water, dried, and weighed. Iron and zinc are estimated in the liquid by warming and precipitating with excess of ammonia and ammonium sulphide. The precipitate, after washing, is ignited, very cautiously at first, and finally with the blow-pipe, and then weighed. The mixed oxides of iron and zinc are then dissolved in hydrochloric acid, and the iron is precipitated with ammonia. The amount of zinc may thus be obtained by difference.

—A. S.

*Zinc Sulphide, Precipitation of, in Gravimetric Determination of the Metal.* J. Meunier. *Comptes Rend.* 124, [21], 1151.

THE difficulty experienced in collecting zinc sulphide for gravimetric determination is overcome by the author in the following simple manner:—The zinc solution, preferably slightly warmed, is precipitated with ammonia, just sufficient of the precipitant being cautiously added to redissolve the hydrate at first formed. A slow current of sulphuretted hydrogen is then passed through the solution, until a drop of it, on a white tile, gives a blackish coloration with another drop of a solution of ferrous sulphate. When this occurs the whole of the zinc will have been precipitated, and is in a suitable condition for collection. The passage of the gas is immediately stopped, and the zinc sulphide collected, washed, and dried in the usual way. It will be found that the filtrate will at once run perfectly clear, and that the precipitate may be rapidly washed, especially if warm solutions be employed. The presence of large quantities of other salts does not affect the ease and rapidity with which the process may be conducted.

—J. O. B.

*Nitrous Acid, Colorimetric Estimation of Small Quantities of.* E. Riegler. *Zeits. Anal. Chem.* 1897, 36, 306.

IN furtherance of the author's communication on the detection of nitrous acid by means of naphthionic acid (this Journal, 1897, 261), the following colorimetric method is recommended for the estimation of small quantities of nitrous acid:—Dissolve 0.406 gm. of pure silver nitrite in hot distilled water, treat with sodium chloride in slight excess, allow to cool, and dilute to 1 litre. After settling the precipitate, dilute 100 c.c. of the clear solution with water to 1 litre. 100 c.c. of this solution, corresponding to 0.001 gm. of  $\text{N}_2\text{O}_3$ , are transferred to a flask, about 0.05 gm. of crystallised naphthionic acid and 5 or 6 drops of strong hydrochloric acid are added, and, after thoroughly shaking the mixture, 30 drops of ammonia are added. A rose-coloured solution is obtained, the coloration of which serves as an index of the above degree of concentration. For the estimation of nitrous acid in water, 100 c.c. are placed in a flask, about 0.05 gm. of naphthionic acid and 5 drops of strong hydrochloric acid are added, well shaken and treated with 30 drops of strong ammonia. The intensity of colour is then compared with a colorimeter, against that of the standard. In this manner it is possible to determine 0.00001 gm. of  $\text{N}_2\text{O}_3$  in 100 c.c. of water.—D. B.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*$\alpha$ -Naphthol from  $\beta$ -Naphthol, A Reaction permitting the easy Distinction of.* E. Legér. *J. Pharm. Chim.* 1897, 5, 527—529.

A cold saturated aqueous solution of the naphthols made by trituration in a mortar, gives a distinctive coloration with sodium hypobromite. This reagent is obtained by mixing 30 c.c. of caustic soda of 36° B. with 100 c.c. of water and shaking with 5 c.c. of bromine. To 10 c.c. of the naphthol solution add 2 drops of the hypobromite,  $\alpha$ -naphthol gives a dirty violet coloration or precipitate, the coloration is even given by a saturated solution diluted with 9 volumes of water.  $\beta$ -naphthol gives a yellow coloration,

becoming greenish and returning to yellow. This reaction is less sensitive, the saturated solution diluted with 2 volumes of water giving a coloration which at once disappears on agitation. The reaction permits of the recognition of 1 part of  $\alpha$ -naphthol in 100 parts of  $\beta$ -naphthol.—A. C. W.

*Stearin in Spermaceti, A Simple Test for Detecting.*

E. Hirschsohn. Pharm. Centralh. 38, 283.

One gram. of the spermaceti is dissolved in 10 c.c. of petroleum ether. If the solution be turbid the sample is probably adulterated. It is then shaken with an equal volume of a 1 per mille cupric acetate solution. If only 2 per cent. of stearin be present, the petroleum ether layer acquires a green colour.—J. O. B.

*Potato Starch and Potato Flour.* Saare. Papier Zeit.

1897, 30, 1059.

See under XVI., page 623.

*Active Diastase, Uncertainty of the Guaiacum Reaction for.* B. Pawlewski. Ber. 1897, [10], 1313—1314.

According to Lintner, the addition of a solution of active diastase to an alcoholic solution of guaiacum resin containing a few drops of hydrogen peroxide, produces a blue coloration either instantly or within a few minutes, whilst invertin, pepsin, and other similar ferments do not give this action. The reaction has been inserted without comment in several subsequent works.

When the coloration is immediate, it may be taken as proof of the presence of active diastase, if there be no other substance in the solution capable of producing a blue coloration. But when the coloration appears in a few minutes, the evidence is not conclusive that diastase is present, because peptone, gelatin, albumin, &c. produce similar colorations, and guaiacum tincture is even coloured blue by hydrogen peroxide without the presence of other substances; in a weak freshly prepared solution the coloration being immediate, and in a strong dark solution appearing after 3—5 minutes.

The reaction may be used as a test for the presence of  $N_2O_3$  and  $HNO_3$ , a deep blue coloration being instantly produced by 0.00005 gram. of sodium or amyl nitrite. Other oxidising agents—ozone, chlorine, bromine, iodine, nitric acid, nitric and chromic acids, permanganate, ferricyanide, &c.—also give blue colorations; thus the reaction loses its value as a test for diastase.—A. C. W.

*Alkaloids, Action of Tannin and Gallic Acid on certain.*

O. de Coninck. Comptes Rend. 1897, 124, 773—775.

THE author has investigated the action of tannin and gallic acid on nicotine and cicutine, under varying conditions. The following reactions are of value:—Two solutions of tannin, A and B, containing respectively 1.434 grms. and 0.0223 gram. of tannin dissolved in 19 c.c. of water, were employed.

0.1 c.c. of nicotine dissolved in 150 c.c. of water yields, with 0.1 to 0.5 c.c. of solution B, a yellow coloration. After a time the liquid becomes opalescent and slightly fluorescent. 0.2—0.3 c.c. of nicotine dissolved in water is precipitated on addition of a drop of solution A, the limit of precipitation being reached at a dilution of about 2 litres. A solution of 0.1 c.c. of cicutine in water yields a precipitate with one drop of solution A, so long as the dilution does not exceed 175 c.c. The opalescent liquid, which at first exhibits a bluish-white fluorescence, gradually acquires a yellow colour, and develops an intense green fluorescence, persistent for at least 12 hours. (See this Journal, 1897, 470.)—H. T. P.

**ORGANIC CHEMISTRY.—QUANTITATIVE.**

*Nitrogen, The Combustion of.* O. Bleier. Ber. 1897, [10], 1269.

THE nitrogen is mixed with oxygen in the proper proportion, brought into a suitable vessel (an enamelled autoclave or a very strong-walled explosion pipette) containing dilute alkali, and a large quantity of electrolytic gas is pumped in. The mixture is exploded and shaken up, to promote the absorption of oxides of nitrogen. The operation must be

repeated several times. (Compare this Journal, 1897, 466—467.)—A. C. W.

*Xylidines, Commercial; Estimation of.* W. Vanbel. Zeits. Anal. Chem. 1897, 36, 285—289.

THE following bases are present in commercial xylidines:—

- I.— $CH_3.CH_3.NH_2$  1.2.4 =  $\alpha$ -amido-orthoxylylene.  
 II.— $CH_3.CH_3.NH_2$  1.2.3 =  $\beta$ -amido-orthoxylylene.  
 III.— $CH_3.CH_3.NH_2$  1.3.4 =  $\alpha$ -amido-metaxylylene.  
 IV.— $CH_3.CH_3.NH_2$  1.3.2 =  $\beta$ -amido-metaxylylene.  
 V.— $CH_3.CH_3.NH_2$  1.4.2 = amido-paraxylylene.

The chief constituents are  $\alpha$ -amido-metaxylylene or asymmetric metaxylyline and amido-paraxylylene or paraxylyline. The percentage of the former is usually estimated by converting the base into the corresponding hydrochloride or acetate, both compounds being insoluble in water. When glacial acetic acid is used as precipitant, equal quantities of acid and base give the best results. More accurate results are, however, obtained by converting the acetate into the bromide. Asymmetric metaxylyline takes up one atom of bromine; and although  $\beta$ -amido-metaxylylene behaves in a like manner, its salts, especially the hydrochloride, are readily soluble. The other bases form dibromides with bromine.—D. B.

*Sumach, Adulterations of, and Methods for their Detection.* M. Spicz. Chem. Centralbl. 1897, 1101—1102.

SUMACH is adulterated with the leaves of *Tamarix africana* (Bruea) and *Pistacia lentiscus* (Stinceo). These adulterations may be detected in several ways. By a nitrogen determination, ash determination, or analysis of ash, as the following figures show:—

	Sumach.	Bruea.	Stinceo.
Nitrogen per cent. ...	0.87—0.98	1.48—1.99	1.47—2.01
Ash „ „ „ „ „ „	6.6	12.4	5.4
Per Cent. of Ash.			
$S_2O_3$ and insoluble ...	24.050	37.100	6.200
$CaO$ .....	29.950	8.530	25.300
$SiO_2$ .....	4.670	20.130	5.218
$MnO$ .....	6.250	9.368	5.760
$Al_2O_3 + Fe_2O_3$ .....	7.150	7.400	7.410
$CO_2$ .....	12.600	1.130	13.750
$P_2O_5$ .....	3.344	1.113	4.021
$Cl$ .....	3.101	4.405	5.321
$K_2O$ .....	6.305	7.950	14.604
$Na_2O$ .....	2.004	2.630	12.176
Loss .....	0.576	0.235	0.240
	100.000	100.000	100.000

Adulterations may also be determined by a colorimetric method, since sumach gives a colour reaction not given by the adulterants. A solution of 0.15 gram. of safranin in 1 litre of water serves as the standard of comparison. 5 grms. of material are boiled for  $\frac{1}{2}$  hour with  $\frac{1}{2}$  litre of water, the liquid cooled, made up to  $\frac{1}{2}$  litre, and filtered. To 25 c.c. of the filtrate in a beaker 5 grms. of a solution of basic lead acetate (specific gravity at  $15^\circ = 1.184$ ) and 15 c.c. of caustic potash (specific gravity at  $15^\circ = 1.155$ ) are added, and the whole concentrated to 15 c.c. The solution should now be reddish-brown and almost clear. If a noticeable precipitate has formed, or if the liquid is only yellow, the sumach is adulterated. The 15 c.c. are diluted to 250 c.c., and, if necessary, filtered; a solution prepared from pure sumach will now show the tint of the safranin solution. If a filtered sumach extract be warmed with excess of potash and a few drops of ammonium molybdate be added, a chocolate-brown precipitate is obtained; in the presence of Bruea this has a greenish, in presence of Stinceo a yellowish-brown tinge.—A. C. W.

*Fats, Differentiation by the Volume of the contained Fatty Acids.* R. Zalosiecki. Chem. Rev. Fett. u. Harz-Ind. 4, [9], 119—121.

THE differences in volume of the fatty acids in fats being, by reason of their different specific gravities, greater than

is expressed by their weight, the author has sought to apply this as a means of differentiation, particularly in the case of butter and its adjuncts.

The apparatus employed is a 200 c.c. flask with a long neck, graduated to 15 c.c. in divisions of 0.1 c.c., resembling a specific gravity instrument. 10 grms. of fat, filtered, and dried at 100° C., are carefully weighed and saponified on the water-bath, with 4 grms. of purified KHO and 50 c.c. of alcohol of 70°. When the alcohol is all evaporated, the soap is dissolved in hot water and transferred into the measuring vessel, rinsed down with hot water, and treated with 25 c.c. of sulphuric acid to separate the fatty acids, sufficient hot water being added to cause the fatty acid layer to rise into the graduated part of the neck. To ensure rapid clarification of the fatty acid, the water should be hot, and the bottle immersed in a water-bath to maintain the contents at the reading temperature, 80° C. Another plan is to proceed as before with half the quantity of fat, dissolving the fatty acid layer with a known volume of benzene, and reading off the volume of the resulting solution, at room temperature; the first method is, however, considered preferable.

The following results have been obtained:—

	Vol. of Fatty Acids at 89° C.
	C.c.
Table butter, A .....	10.75
" B .....	10.70
Market butter A .....	10.80
" B .....	10.80
Old rancid butter .....	10.85
Old beef tallow .....	10.80
Fresh " .....	10.95
Mutton tallow .....	11.70
Fresh hog's lard .....	11.50
Margarin .....	11.60
" lard .....	11.60
Oleomargarin .....	11.40
Cocoonut oil .....	11.35
" .....	10.95
Olive oil .....	10.90
Rape oil .....	11.25
Linseed oil .....	11.55
Castor oil .....	11.50
" .....	11.30

	Vol. of Fatty Acid in Benzene Solution at 29° C.
	C.c.
Table butter A .....	5.10 (from 5 grms. substance)
" B .....	5.20 " "
Beef tallow .....	5.45 " "
Margarin .....	5.49 " "
Cocoonut oil .....	5.25 " "

The average figure for butter, 10.8 c.c. per 10 grms., is therefore appreciably lower than the figures for the fats used as adjuncts thereto; even if a margin of 0.2 c.c. be allowed on both sides, the difference between the maximum for butter (11.0) and the minimum for butter substitutes of animal origin, amounts to 0.3 c.c. per 10 grms.—sufficient to differentiate between them.—C. S.

*Butter and Margarine, Discrimination between.* A. v. Aboth. Chem. Zeit. 1897, 21, [32], 312—314.

THE author asserts that the lead salts of the soluble fatty acids in butter are as soluble in water as are the acids themselves, and on this he bases the following process for arriving more rapidly at the Hühner and Reichert values:—The saponification value is determined on 2.5 grms. of the fat. The resulting soap is decomposed with a solution of lead acetate, and the lead soap filtered and washed in a linen cloth, which is squeezed in the hands to remove water. The insoluble lead salts are decomposed by being shaken in a Muter tube with ether and hydrochloric acid, the ethereal solution washed with water, its volume read off, an aliquot portion run into a weighed flask, the ether evaporated, and the fatty acids dried and weighed. From the result the

total weight of insoluble fatty acids can be calculated and the Hühner number obtained. The weighed fatty acids are then titrated with standard alkali and the result calculated on 2.5 grms. The difference between the number of c.c. of decinormal alkali required by the total fatty acids and those used by the insoluble fatty acids gives the Reichert value.

—C. A. M.

*Hübner's Iodine Solution, The Behaviour of Tannic Acids and Tannin Extracts towards.* C. Boettinger. Chem. Zeit. 21, [46], 460.

THE author refers to his previous communications on the behaviour of gallic acid, tannin, and the acetyl derivatives of these bodies towards solutions of iodine and mercuric chloride (Chem. Zeit. 1896, 20, 984; 1897, 21, 57). He has now examined the acetyl compounds of the tannins of oak bark, oak wood, and pine bark; these compounds give practically no iodine number. The pure tannins were then prepared from the acetyl compounds by the author's method (this Journal, 1884, 526; and 1887, 550. Also Ann. 1887, 238, 370). They gave iodine numbers varying according to the quantity of iodine and the concentration.

The tannic acid of oak bark gave iodine numbers from .....	120.4—134.5
The tannic acid of oak wood gave iodine numbers from .....	39.2—51.4
The tannic acid of pine bark gave iodine numbers from .....	46.4—55.9

The use of chloroform as a solvent of the tannic acids is quite unnecessary.

The same tests were applied to the extracts of different tanning materials, with the following results:—

	Mean Iodine Number.
1. Oak-wood extract .....	29
2. Pine bark .....	90
3. Oak bark .....	106
4. Algarobilla .....	114
5. Camagre .....	119
6. Valencia .....	153
7. Pegu catechu .....	164
8. Sumach .....	165
9. Quebracho wood .....	188
10. Terra japonica .....	202

These figures are the mean of 6—8 experiments, the mean numbers for the pure tannins being: oak bark, 130.1; oak wood, 45.8; pine bark, 50.3.—J. T. W.

*Starch, Control of the Manufacture of.* Hébert. Bull. Assoc. Chim. 1897, 14, 1003.

See under XVI., page 623.

*Meat Extracts, Analysis and Composition of.* J. Bruylants. J. Pharm. Chim. 1897, 5, 515—521.

COMPARE this Journal, 1895, 897; 1896, 130, 140, 897. The quantitative method of analysis was as follows:—Water, ash, sodium chloride, total nitrogen, nitrogen as ammonium salts, matters insoluble in water, and nitrogen in this insoluble part were determined according to ordinary methods. Then gelatin, albumoses, peptone, non-albuminoid nitrogenous substances soluble and insoluble in alcohol, were separated by successive treatment with alcohol of 40, 80, and 93—94 per cent. Gelatin is thrown down by 40 per cent., albumoses by 80 per cent., and peptones by 93—94 per cent. alcohol. These precipitates are far from pure. After purification, the nitrogen in each was determined; this, multiplied by 6.25, gives the amount of gelatin, albumose, or peptone.

10 grms. of dry extract or 20 grms. of liquid extract were dissolved in water, the insoluble part filtered off and washed. After drying, nitrogen was determined in this residue by Kjeldahl's method. The solution was heated to boiling and filtered hot; the precipitate gives the coagulable albumin. The filtrate was evaporated to the consistence of a solid extract, and several times extracted by 80 per cent. alcohol. The solution, A, contains peptones, non-albuminoid nitrogenous substances, mineral salts, glucose, sarcosine, &c. The residue, B, contains gelatin, albumoses, some non-

albuminoid nitrogenous matters, mineral salts, &c. This residue, washed with 80 per cent. alcohol and freed from alcohol on the water-bath, was dissolved in 60 c.c. of distilled water, 40 c.c. of absolute alcohol were added, and the mixture left for 24 hours. The solution, B, contains albumoses, non-albuminoid nitrogenous matters, and mineral salts; the residue B, mineral salts and gelatin. This residue, after washing with 10 per cent. alcohol, was used for the gelatin determination.

The solution B, after addition of the wash liquors of residue B, was evaporated to 10 c.c., poured into 30 c.c. of saturated ammonium sulphate solution, a slight excess of the same salt added, the mixture heated to boiling, and filtered. The precipitate of albumoses thus obtained was washed with ammonium sulphate solution, dissolved in water, and ammonia driven off by barium carbonate; the nitrogen determination now gave the amount of albumoses. The ammonium

sulphate solution, freed from ammonia, was used for a nitrogen determination, half of which belongs to non-albuminoid matters and half to peptones. The solution A was evaporated to the consistence of extract, dissolved in the least possible quantity of 80 per cent. alcohol, and absolute alcohol added to bring up the percentage to 93—94. After 24 hours the solution was decanted and the residue again treated in the same way. The precipitate was dissolved in 100 c.c. of water, a slight excess of basic acetate of lead added; after 24 hours the mixture was filtered and the precipitate taken up in 100 c.c. of water. The nitrogen found in the precipitate belongs to the non-albuminoids. The lead acetate liquors, freed from lead by sulphuretted hydrogen and evaporated, give the peptones.

The solution in 93—94 per cent. alcohol, after evaporation, also gives non-albuminoids. The nitrogen in this residue is given in the table as "nitrogen soluble in strong alcohol."

*Horseflesh, Detection and Estimation of, in Sausages and Meat Preparations.* H. Bremer. *Forschungs-Ber.* 1897, 4, 1—8.

THE various processes proposed for the detection of horseflesh are based either on the glycogen reaction or on an examination of the fat. To the latter class belongs the author's method, which consists in extracting and examining the intra-muscular fat. The finely minced sample, from which all visible fat has been removed, is heated with water on the water-bath for an hour. The fat rising to the surface is poured away, and the flesh washed several times with hot water, well dried at 100°, and extracted for several hours with a low-boiling petroleum spirit. Part of the intra-muscular fat thus obtained is used for the determination of the refractive index, iodine number, and Reichert-Meissl number. The remainder is saponified and converted into zinc salts, which are extracted with ether. The fatty acids are liberated from the soluble portion, and their iodine number determined.

In this way the author obtained the subjoined results:—

	Iodine No. of Intra- Muscular Fat.	Iodine No. of Liquid Fatty Acids.
1. Horseflesh sausage, without pork.....	75.8	108.1
2. Horseflesh sausage, with about 6 per cent. of pork.	74.9	104.1
3. Horseflesh cervelat, with about 22 per cent. of pork (well smoked).	53.7	92.4
4. Horseflesh cervelat, with about 25 per cent. of pork.	74.1	102.1
5. Ordinary sausage.....	57.6	91.2
6. Thüringian cervelat, with about 65 per cent. of lard.	64.3	95.8
7. Mixture of 1 and 5 in equal parts.....	65.4	103.1
8. " 4 and 6 " " .....	65.2	99.5

It is stated that when horseflesh is present the petroleum spirit extract and the liquid fatty acids have a more or less reddish colour. On the other hand, the flesh of bulls gives a similar coloration; so that this must only be regarded as confirmatory evidence. When, however, the red colour is present, and when at the same time glycogen is detected, while the iodine number of the intra-muscular fat exceeds 65, and that of the liquid fatty acids is considerably over 95, there can, in the author's opinion, be but little doubt as to the presence of horseflesh.—C. A. M.

*Theobromine, Determination of, in Cocoa and Chocolate.*

L. Maupy. *J. Pharm. Chim.* 1897, [6], 5, 329.

THE quantity of the sample taken for the following process is generally 5 grms. for cocoa of good quality; if it is desired to increase the amount of alkaloid available for final weighing, more of the sample may be used.

The finely crushed cocoa is placed in a flask with 60 grms. of petroleum ether or ligroin; the flask is well corked and the mixture shaken occasionally for a day. The powder and liquid are then thrown upon a plain filter, drained, and, after washing with a little more of the solvent, the cocoa is dried. The dry cocoa free from fat, thus obtained is now triturated with 2 grms. of distilled water, the moist mass introduced into a small flask with 20 grms. of a mixture of pure crystalline phenol, 15 parts; chloroform, 85 parts, and boiled under a reflux condenser for one hour; the mixture is then filtered, preferably by the aid of a filter pump, and the residue again extracted twice with further portions of the phenolchloroform solvent, boiling for 30 minutes on each occasion. The mixed chloroformic extracts are distilled, the last traces of chloroform being carefully driven off; to the cold residue 40 grms. of anhydrous ether are added, and, after well shaking, the mixture is left for six hours. Theobromine is precipitated, while caffeine, colouring matter, and traces of fat remain in solution. The precipitated alkaloid is thrown on a counterpoised filter, washed with a few c.c. of ether to remove

the last traces of phenol, dried, and weighed. The alkaloid should be white or scarcely tinted, even in the case of roasted cocoas or chocolate.

With chocolate 10 grms. are taken, the fat is removed with petroleum ether, and the powder then mixed with 4 grms. of 70 per cent. alcohol, and the assay continued as described above for 5 grms. of cocoa. Should the amount of sugar present exceed 50 per cent., the amount of phenol-chloroform solvent is reduced so as to employ about 60 centigrms. of phenol for every gm. of cocoa considered present as chocolate, the volume of the liquid being made up by more chloroform. The following percentages of theobromine were obtained by the author with this method:—

	Per Cent.
Roasted Trinidad.....	1.44
.. Caracas.....	1.38
.. Grenada.....	1.60
.. Para.....	1.28
.. Martinique.....	1.52
Chocolate (60 per cent. of sugar) .....	0.54

—J. O. B.

*Alcohol, The Estimation of, by the Vaporimeter.*  
F. Rothenbach. *Wochenschr. f. Bran.* 1897, **14**, 189.

THE author considers the vaporimeter to be an utterly untrustworthy instrument, especially when employed for the estimation of alcohol in impure liquids, such as vinegar, mashes, beer, &c., which contain substances (including dissolved  $\text{CO}_2$  and air) able to influence the alcoholic vapour tension. He recommends for the examination of the materials referred to, the well-known distillation process.

—H. T. P.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Platinum Chloride, Recovery of Waste.* H. W. Wiley.  
*J. Amer. Chem. Soc.* 1897, **19**, 258—261.

THE author mentions that the following method has been worked out by K. P. McElroy. The waste platinum from potash determinations is collected, dissolved in water, and aluminium in the form of clippings or turnings added to the hot solution. In a few minutes a platinum-aluminium couple is formed, and reduction proceeds vigorously. The addition of hydrochloric acid is advisable to facilitate the deposition of the platinum, and when the reduction is complete, more hydrochloric acid is added to dissolve the excess of aluminium. The spongy platinum is well washed by decantation, and treated with nitric acid to remove any traces of copper; it is again washed, and dissolved in aqua regia (5 parts of hydrochloric to 1 part of nitric acid). The solution thus obtained is evaporated, dilute hydrochloric acid added, and re-evaporated. Should nitrous fumes be evolved on the addition of water, the solution is evaporated, and this treatment continued until the nitric acid is removed. The resulting solution of platinum chloride is then diluted and filtered.—J. L. B.

*Phosphorus, A New Oxide of.* A. Besson. *Comptes Rend.* 1897, **124**, 763—765.

THE new oxide, to which the author assigns the formula  $\text{P}_2\text{O}_3$ , is obtained by the action, at  $50^\circ \text{C}$ , of hydrogen phosphide on a mixture of phosphorus oxychloride with hydrobromic acid, or a bromo-oxy compound of phosphorus; or, preferably, by heating to  $50^\circ \text{C}$  a mixture of phosphonium bromide and phosphorus oxychloride. The oxide separates in the solid state, and, when pure, forms a reddish-yellow voluminous powder, which is stable at ordinary temperatures and at  $100^\circ \text{C}$ . When heated to  $135^\circ \text{C}$  in *vacuo*, it loses oxygen until the percentage of phosphorus in the residue attains 90—95. The oxide is combustible, and reacts in the same way as phosphorus with nitric acid. It burns vividly when projected into chlorine. When the reaction is moderated by operating with a carbon tetrachloride solution of the gas, the product formed is either  $\text{PCl}_3$  or  $\text{PCl}_5$ , according as the chlorine or oxide is present in excess. Under the same conditions, bromine forms  $\text{POBr}_3$ , and

either  $\text{PBr}_3$  or  $\text{PBr}_5$ ; whilst with iodine the sole product is  $\text{PI}_3$ .

$\text{P}_2\text{O}_3$  appears to be a neutral body. It is insoluble in water and dilute alkaline solutions, and even when heated to  $150^\circ \text{C}$  with water, is only slightly attacked, yielding traces of phosphorous acid and hydrogen phosphide.

Phosphonium iodide acts quite differently on phosphorus oxychloride, the products being  $\text{P}_2\text{I}_4$ , an intimate mixture of red phosphorus and iodine, and metaphosphoryl chloride ( $\text{PO}_2\text{Cl}$ ).—H. T. P.

*A Vegetable Lipase, extracted from Penicillium Glaucum.*  
E. Gérard. *J. Pharm. Chim.* 1897, **5**, 529—530.

A SOLUTION of 2 grms. of monobutyrin in 100 c.c. of water to which 0.3 gm. of the soluble ferments of *Penicillium glaucum* was added, showed a continual increase in acidity, due to saponification of the ester. Sigmund (*Monatsh. für Chem.* **13**, 567) states that ferments which decompose glucosides also saponify fats. The ferments of *Penicillium* contain emulsin, but the author did not observe any appreciable saponification of monobutyrin by that ferment.

—A. C. W.

*Strontium Sulphide, A Method for preparing highly Phosphorescent.* J. R. Mourelle. *Comptes Rend.* 1897, **124**, 1024—1026.

THE author has experimented with several methods—described in detail—for the preparation of strontium sulphide, and finds that by far the best results, so far as phosphorescent power of the product is concerned, are obtained as follows:—

An intimate mixture of 285 grms. of commercial strontium carbonate, 62 grms. of flowers of sulphur, 4 grms. of crystallised sodium carbonate, 2.5 grms. of salt, and 0.4 gm. of bismuth subnitrate, is placed in a crucible, covered with a layer of coarsely powdered starch, and submitted for five hours to a bright red heat, and subsequently allowed to cool very slowly (10—12 hours). A white, friable mass is thus obtained, which develops a fine greenish-blue fluorescence when exposed for about one second to daylight, and so intense as to be plainly visible in a shaded situation. The author remarks, however, in conclusion, that the greater number of his preparations became perfectly inert when powdered, although in some instances the phosphorescent power of the sulphide was restored by re-ignition in contact with starch.—H. T. P.

*Phosphorescence of Strontium Sulphide.* J. R. Mourelle. *Comptes Rend.* 1897, **124**, [25], 1521—1523.

WHILE the phosphorescence of calcium sulphide varies considerably in colour, with even slight variations in the conditions of its preparation, that of strontium sulphide is remarkably constant, being a more or less greenish-blue. The tint varies slightly, and the intensity to a greater degree, with the source of the sulphide: the most intense, and the greenest, being that of the sulphide prepared from a mixture of strontium and sodium carbonates, sodium chloride, and bismuth subnitrate, while the least intense is the bluer phosphorescence of the sulphide reduced from the sulphate by lamp-black.

The author has made experiments on the sulphides prepared as above, and also by the action of hydrogen sulphide and of sulphur on strontia, and by Verneuil's method, in which the samples, prepared in the first instance at different temperatures and after different periods of heating, were afterwards exposed for varying periods to further heating, sometimes at temperatures above those of preparation. In no case (provided care had been taken to avoid any oxidation) was there any change produced in the colour or intensity of the phosphorescence of the sample: so that temperature seems to have but little influence on the phosphorescence.—J. T. D.

*Chromium, The Atomic Weight of.* Eng. and Mining J., June 26, 1897, 655.

INVESTIGATIONS in pure science are often unintelligible to the practical man, and generally appear useless; yet sometimes their bearing upon technology and industry is

exceedingly direct. An instance of this kind is pointed out by Mr. F. W. Clarke in a recent number of the *Journal* of the American Chemical Society. The question is often asked, Why are new determinations important? Are not those now accepted good enough for practical purposes? To this question Mr. Clarke makes the following answer:—

There are two rival values for the atomic weight of chromium. The one, 52.5, based on the old work of Berlin, is used by European analysts; the other, 52.1, based on later researches, is used in the United States. The Baltimore Chrome Ore Works imports chromic iron in cargoes of about 2,500 tons, which are assayed in Glasgow and Baltimore. The chemists of the former city based their percentage calculation on the atomic weight of chromium, 52.5, and those of the latter place on 52.1. The variation in percentage resulting from this amounts to a difference of 3.67-50 dols. in the value of a cargo.

## Obituary.

### PAUL SCHÜTZENBERGER.

SCHÜTZENBERGER was born Dec. 23rd, 1827, at Strasburg. He first gave himself to the study of medicine, but later on he became devoted to chemical science, which then and throughout the remainder of his life, absorbed his whole attention. From 1854 to 1861 he was a lecturer in the Real-school, and still later he became lecturer in the High School at Mulhouse. In 1865 he was assistant in the Collège de France, Paris, and prepared the experiments, &c. for Ballard's lectures; and in 1868 he was advanced to the position of second director of the chemical laboratory at the Sorbonne, in 1876 becoming Professor in the Collège de France. On the foundation of the School of Chemical Industry and Physics, in the year 1882, Schützenberger was chosen as director of that institute. As the successor of Dumas, he was elected a member of the Academy of Medicine, and, as the successor of Debray, as a member of the Academy of Sciences; and finally, he obtained the rank of an Officer of the Legion of Honour for distinguished services to his country.

Schützenberger was the first to point out the law of the substitution of the metals in salts by electro-negative elements. The highest interest also attaches to the chloracetate  $C_2H_3O_2Cl$ , first prepared by him, in which chlorine plays the part of a metal. In Schützenberger's researches he displayed marvellous versatility, attacking with uniform success problems in the fields of physiological, organic, and inorganic chemistry. His researches on the natural dyestuffs must also be recorded; on madder, cochineal, woad, and indigo. Likewise, his very important investigations on the respiration and changes of beer yeast; also on the constitution of the albuminoids, with the aid of baryta water under pressure, according to which these albuminoids must be regarded as crystalline substances. In Germany he probably won most renown by his work, published in 1866, on Dyestuffs and Colouring Matters, as well as by the discovery, made conjointly with Lalande, of the "Hydrosulphite Vat."

But he also published a remarkable work on Physiological Chemistry, a monograph on The Phenomena of Fermentation, and his great text-book on General Chemistry.

In the latter years of his life he entirely devoted himself, with several of his students, to the study of the rare earths. He was the originator of the communications on "Lueium"—a hypothetical element supposed to belong to the Yttrium group of metals. In Paul Schützenberger, France has lost one of the most gifted and original of her chemists. He died in Paris, on the 26th of June 1897.—W. S.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

FRANCE.

#### Customs Decisions.

The following decisions as to the classification of articles in the French Customs tariff have been communicated by the Director of French Customs:—

Mastic for cycles, composed of caoutchouc or gutta-percha and vegetable rosin, with or without the addition of mineral matter, is to be classed as vegetable rosin (No. 115).

Or brilliant or glanz gold is classified as a "chemical product, not denominated, of a base other than alcohol" (No. 282). *Platine brillante* and *Argent brillante* will be classed under the same category.

NETHERLANDS.

#### Removal of Duty on Aniline Oil.

U.S. Cons. Reps., July 1897, 464.

The United States Minister at The Hague reports, on May 24, 1897:—

By royal order of May 8, 1897, appearing in the *Netherlands Gazette* of to-day, aniline oil is declared to be exempt from import duty.

PORTUGAL—EAST AFRICA.

#### Classification of Sulphuric Acid.

A despatch, dated 16th June last, has been received at the Foreign Office from Sir H. G. Maedonell, Her Majesty's Minister at Lisbon, stating that, by a ministerial decree of June 15 last, it is provided that, as in the Imports Customs tariff for the province of Mozambique no mention is made of chemical products, sulphuric acid must be classified, for the payment of the duty leviable thereon, under Article 42 of the Mozambique Customs Tariff of December 29, 1892.

UNITED STATES.

#### Customs Decisions.

The following decisions relating to the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the authorities in that country:—

Alizarin black, a coal-tar colour or dye, is liable to duty at 35 per cent. *ad valorem* under paragraph 18 of the Act of 1890.

Nucua-nut oil, or "nucua butter," or "solidified cocoa-nut oil" is classified as "cocoa butterine," at the rate of 3½ cents per lb. under paragraph 230 of the Act of 1894.

"Fibrite," artificial sulphate of lime, is classified for duty at 25 per cent. *ad valorem* under paragraph 39 of Act of August 28, 1894.

Potato starch or potato flour is dutiable at 1½ cents per lb., as provided in paragraph 232 of the Act of 1894, for starch.

CARBOLINEUM IN NICARAGUA.

U.S. Cons. Reps., June 1897, 269.

On the 9th of March 1897, the Government of Nicaragua issued a decree by which the duties on the importation of carbolineum are abolished.

Carbolineum, or crude carbolic acid, is used in this country to a great extent for the killing of insects, and will find a ready market here at this time of the year, when the dry season is giving place to the rainy one, and obnoxious insects are abundant.

SPIRIT DRAWBACK IN CANADA.

Chem. and Druggist, July 10, 1897, 41.

The Canadian Government have, in response to an agitation in the drug trade there, permitted druggists to obtain a drawback of 75 c. per proof gallon on spirit used for the production of preparations in the manufacture of which alcohol is destroyed for potable purposes. The same rate has hitherto been allowed to perfumers only.

## OFFICIAL NOTICES.

## BOARD OF TRADE COMMITTEE ON CONSULAR REPORTS.

*Standard, July 21, 1897.*

The Board of Trade have appointed a Committee consisting of the following gentlemen, *viz.*, Sir Courtenay Boyle (Chairman), Sir H. Stafford Northcote, M.P., Sir Henry Berghie, Mr. S. E. Spring Rice, and Mr. A. E. Bateman, to consider and advise as to the best means of bringing to the knowledge of the home trades the information furnished by Consuls and Commercial *Attaches*, and by Agents-General and other representatives of Colonial Governments and of India, as to the supply and demand and other conditions of the markets in their respective districts; and as to the opportunities which they afford for the introduction and development of British trade; also to report whether it is, in their opinion, desirable that Consuls and Agents should be instructed to remit home from time to time samples of goods most in demand in such markets; and, if they shall be of that opinion, to advise what (if any) arrangements should be made for the exhibition of such samples in London, or for their circulation, with the aid of Chambers of Commerce, to the provincial trade centres, with information as to price, and other conditions under which they are supplied. Mr. G. J. Stanley, of the Board of Trade, will act as secretary to the Committee.

## CARBIDE OF CALCIUM.

Since the Order in Council of the 26th February 1897, in virtue of which certain parts of the Petroleum Acts 1871 to 1881 were applied to carbide of calcium, the question of the expediency of exempting small quantities of this substance from the operation of the Order has occupied the attention of the Home Office, and the Secretary of State having been advised that such exemption might be safely extended to quantities of carbide of calcium not exceeding 5 lb., when kept in separate substantial hermetically-closed metal vessels containing not more than 1 lb. each, an Order in Council was made on the 7th of July, authorising the keeping of not more than 5 lb. of carbide of calcium in vessels as above described without a licence, and the original Order of the 26th February has been amended accordingly.

The amending Order appeared in the *London Gazette* of the 9th July. It is to be observed that where the carbide of calcium is not kept in vessels as above described, no quantity may be kept without a licence.

## PROPOSED NATIONAL PHYSICAL LABORATORY.

*Standard, Aug. 4, 1897.*

The Treasury have appointed a committee to consider and report upon the desirability of establishing a National Physical Laboratory for the testing and verification of instruments for physical investigation, for the construction and preservation of standards of measurement, and for the systematic determination of physical constants and numerical data useful for scientific and industrial purposes, and to report whether the work of such an institution, if established, could be associated with any testing or standardising work already performed, wholly or partly, at the public cost. The following will be the members of the committee:—Lord Rayleigh (Chairman), Sir Courtenay Boyle, Sir Andrew Noble, Sir John Wolfe Barry, Mr. W. C. Roberts-Austen, Mr. Robert Chalmers (of the Treasury), Mr. A. W. Rüchker, Mr. Alexander Siemens, and Dr. T. E. Thorpe.

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

## AMERICAN DRUG PREPARATIONS IN FRANCE.

*U.S. Cons. Reps., June 1897, 215.*

Inquiries having been made at the U.S. Consulate at Limoges by certain leading druggists of Central France concerning certain American preparations of drugs, a few samples were shown to them, with which they expressed themselves very pleased. It seemed to these gentlemen that a good opportunity for introducing these goods presents itself.

The following list of drugs are those most usually prescribed in this country: Sulphate of quinine, opium, nuxvomica, Dover's powders, lithia, chlorate of potash, bromide of potassium, bromide of sodium, salicylate of soda, iodide of potassium, and others that enter into the daily use of a physician having a general practice. A certain quantity of proprietary medicines might find a ready sale if put upon the market in a wise manner, but it will be absolutely necessary to have the formulas printed on every bottle. Such common preparations as seidlitz powders and citrate of magnesia, and heavy drugs like glycerin, borax, potash, cod-liver oil, borate of soda, caustic soda, and alkalis are used in large quantities in this country. The French druggists have been deterred from using American drug preparations because the weights and measures employed by the exporters from the United States are not the same as those in use in France; the decimal system is the only one known here—grains, drachms, and ounces are unknown quantities to the laity, and the profession will not take the trouble to translate the weights into grams and milligrams so as to find out what dose to give. The French admit that the manner of putting up drugs in the United States is greatly superior to that of other countries, but the system of foreign weights, measures, and currency forms a barrier to their introduction into this Republic. All drugs should be put in neat, but not too large, packages; the matter of colour and taste are important items to take into consideration, because the masses are not accustomed to taking medicine without a doctor's prescription, as are the people of the United States.

## THE WORLD'S ALUMINIUM OUTPUT.

*U.S. Cons. Reps., June 1897, 322.*

The United States Consul at Zürich reports as follows:—The aluminium production in the different countries, together with the horse-power employed and the daily capacity of each plant, is given in the following table:—

Works.	Horse-Power.	Average Daily Production.	
UNITED STATES.			
Pittsburg Reduction Company's Works:—		Kilos.	Lb.
At Kensington, Pa. ....	1,600	906	1,993
At Niagara Falls, N.Y. ....	1,600	1,000	2,200
SWITZERLAND.			
Aluminium Ind. Gesellschaft, Neuhausen.	4,000	2,270	4,994
FRANCE.			
Société Electr. Mét. Franc., at Lapraz.	2,500	1,360	2,992
Société Ind. de l'Aluminium, at St. Michel.	2,000	1,134	2,493
Total .....	11,700	6,670	14,674

Or, in round numbers, 6,700 kilos. (14,740 lb.), giving at present an annual production of about 2,000 metric tons. The output during 1895 was about 1,200 metric tons. A considerable reduction in the price of aluminium, on account of the additions to works now in operation and their increase in horse-power capacity, as well as the contemplated erection of new plants, is imminent. In Great Britain, the British Aluminium Company has purchased the Irish bauxite pits, for the purpose of manufacturing aluminium at Larne Harbour, near Belfast. The same company has bought water rights at Foyers Falls, in Scotland, where 4,000 horse-power is at its disposition.

The new addition to the Neuhausen works, which is to be operated by the Héroult system, will, when in operation, add 2,700 kilos. (5,940 lb.) to its daily production. A German-American syndicate has planned the erection of works for the manufacture of aluminium at the waterfalls of Sarpfoss, in Norway. The water-power there, it is estimated, will be produce 10,000 horse-power, and the plant is to be ready for operation some time in 1898. If they utilise 5,000 horse-power, a daily production of 3,000

kilos. will result. Further, the Neuhausen company is building new works, with water-power to produce 10,000 horse-power, at Rheinfelden, Switzerland, and has also acquired water rights for similar purposes at Lenz, near Gastein, in Austria.

These new additions (Rheinfelden, 6,000 horse-power; Foyers Falls, 3,000 horse-power; Sarploss Falls, 5,000 horse-power), as well as the increased horse-power capacities projected for the plants now in existence (the increase of 7,100 horse-power at Niagara Falls and 4,000 horse-power at St. Michel), will, in the year 1898, with an aggregate capacity of 33,000 horse-power, turn out an average of 19,300 kilos. (42,460 lb.) daily, or, annually, 5,790 metric tons. It becomes therefore evident that the price of aluminium will fall to about 3 frs. (60 cents) per kilo., or about 27 cents per lb.; so that soon but three commercial metals will be cheaper than aluminium, namely, iron, lead, and zinc.

#### BRIMSTONE IN SICILY.

*U.S. Cons. Reps., June 1897, 203.*

The U.S. Consul at Messina reports as follows:—

(1.) The exports of sulphur from Sicily in 1896 were 44,000 tons in excess of 1895, of which 31,000 tons were exported from January to July. This increase is to be attributed to the exceedingly low prices which prevailed towards the close of 1895 and beginning of 1896, at which figures the working of a majority of the mines was unprofitable. The increase of 13,000 tons in the last six months of 1896 is undoubtedly due to the sudden advance in prices, which induced consumers to lay in heavy stocks in anticipation of a further rise. These stocks, however, cost them relatively low prices.

(2.) Although prices steadily declined during those years, the production, as estimated by the mining bureau, frequently increased and never decreased. Stocks show a constant increase. These facts unquestionably prove that the cost of production has diminished, cheaper transportation has been gained by the construction of roads and railways, and improvements have been made in mining and smelting. It follows, therefore, that production at the lower prices has continued steadily because it was found profitable.

(3.) The increase of exports during these years is natural, because the large production had to be sold, and this was made possible by the fall in prices.

(4.) The Italian Parliament abolished the export duty of 8s. 6d. (2·66 dol.) per ton with the object of favouring exports, since this duty increased the cost to the foreign consumer. The artificial advance which the Anglo-Sicilian sulphur trust wishes to establish is therefore in opposition to all the above facts, although the latter are responsible both for the decline in price for several years and the abolition of the export duty.

(5.) It is stated that the production in 1896 shows an increase, and although the statistics are not yet published, there is the best authority for estimating it at about 385,000 tons. That there really was an increase is confirmed by the following facts:—There were shipped in 1896, 44,000 tons more than in 1895, but nevertheless the visible stock in the ports of Sicily on the 31st of December 1896 was only 18,000 tons less than on the same date in 1895. The difference of 26,000 tons must therefore come from an increase of production, which, in part at least, belongs to 1896, as some of this quantity may be sulphur stored in the mines in 1895 and not shipped promptly. Further, the quantity carried by rail from the stations in the interior to the ports was larger in the fiscal year 1895-96 than in 1894-95.

(6.) Everything points to an increased production for 1897, and if the present prices check the consumption, stocks must necessarily increase during the year.

(7.) Should Sicilian brimstone be partly replaced in the United States by pyrites for the manufacture of sulphuric acid, this will diminish their imports, which have been from 100,000 to 125,000 tons per annum, or 25 to 30 per cent. of the total production of Sicily.

(8.) For the above reasons, it seems more than doubtful if the Anglo-Sicilian sulphur trust can succeed in maintaining the prices at the present artificial point for any length

of time. Its capital is 750,000*l.* (3,649,885 dol.), and it has purchased its brimstone at about 65s. (15·80 dol.) per ton free on board Sicily, plus all the other expenses.

#### EXPORTATION OF SULPHUR FROM ITALY.

*U.S. Cons. Reps., June 1897, 204.*

According to statistics published by the general direction of the revenue, the sulphur exported from Italy to foreign countries during the year 1896 reached 3,563,700 quintals (1 quintal = 220·46 lb.). The export in 1895 was 3,175,661 quintals; 1891, 2,990,896 quintals; 1893, 3,108,674 quintals; 1892, 2,910,307 quintals.

The exports according to countries, as compared with the preceding year, were as follows:—

Countries.	1895.	1896.
	Quintals.	Quintals.
Austria-Hungary.....	115,967	180,222
Belgium.....	60,182	71,328
France.....	755,291	759,758
Germany.....	171,895	183,896
Great Britain.....	263,576	218,932
Greece.....	114,500	130,110
Holland.....	42,380	41,759
Portugal.....	71,356	111,922
Russia.....	180,004	167,042
Spain.....	120,629	82,149
Sweden and Norway.....	47,992	115,761
Turkey.....	54,752	60,134
United States.....	290,733	1,304,482
South and Central American States..	65,527	27,213
Other countries.....	75,846	82,910
Total.....	3,175,661	3,563,700

#### GENERAL TRADE NOTES.

##### GERMAN CHEMICAL PROFITS.

*Chem. and Druggist, July 31, 1897, 214.*

Dr. Otto N. Witt, President of the German Society for the Protection of Chemical Interests, has published an interesting pamphlet on wages and profits of the German chemical industry, from which the following figures are taken. The average dividends paid between the years 1886 and 1895 by various chemical companies in Germany were as follows:—Industries of alkalis and acids, 7·4 per cent.; pharmaceutical, photographic, and chemico-technical preparations, 12·6 per cent.; coal-tar dyes, 19·2 per cent.; explosives, 16·5 per cent.; artificial manures, 7·5 per cent. The profits in the industry of acids and alkalis show the smallest annual fluctuations, while those on pharmaceutical preparations exhibited the largest difference. The average dividend of the coal-tar dye industry has increased without a break and with remarkable equality since 1886. In that year the average dividend was not quite 10 per cent. In 1891 it was over 20 per cent., and between 1892 and 1895 the average has been 23·45 per cent. Unfortunately there is no means of showing what proportion of this increased profit belongs to the coal-tar remedies, which are now cultivated by most of the factories with at least as much care as the manufacture of colours itself. Companies, however, only form a small portion of the chemical industry. With regard to private firms, there is reason for believing that their average profits amount to from 6 per cent. to 8 per cent. on the capital invested. As a set-off to this profitable condition of things, it must be taken into account that burdens on the industry, in consequence of enforced contributions towards insurance of workmen, &c., are increasing every year. Wages also have risen considerably. In 1891 the average wage of each working man employed in the chemical industry was only 836 m.; in 1894 it had risen to 885 m., and in 1896 to 907 m. In addition to the sick and invalid insurance, the compulsory insurance for accidents absorbs enormous amounts. As an instance, it is mentioned that one chemical factory, employing 1,247 insured persons, paid in 1896 40,849 m. towards accident insurance, 8,640 m. towards invalid insurance, and 11,629 m. towards the sick fund. In addition to this total of 61,180 m., the factory in the same year paid fully 12,000 m. in voluntary assistance to its workmen.

## PRODUCTION OF CELLULOSE IN SWEDEN.

*Board of Trade J., July 1897, 91.*

The production of cellulose in Sweden has, according to a statement in *Le Monde Economique*, rapidly increased since 1867. The following table shows the amount produced in quinquennial periods from 1867 to 1896:—

Periods of 5 Years.	Production by Mechanical Method.	Production by Chemical Method.
	Tons.	Tons.
1867—1871	61,700	—
1872—1876	97,800	5,350
1877—1881	140,000	18,240
1882—1886	194,000	110,000
1887—1891	246,000	202,400
1892—1896	355,900	416,200

## PLATINUM IN NEW SOUTH WALES.

*Eng. and Mining J., July 17, 1897, 67.*

Among the minerals produced in New South Wales during 1896, platinum occupies a position for the first time, the output being valued at 3,479*l.*, says the *Australian Mining Standard*. The production of platinum for many scientific purposes is assuming great importance, and it is to be hoped that the discoveries which have been made in New South Wales will lead to the establishment of a permanent and lucrative industry.

## WORKS' EFFLUENTS IN SEWERS.

*The Leeds Regulations.**Chem. Trade J., July 10, 1897, 19.*

The Streets and Sewerage Committee of the Leeds Corporation have decided that the following resolutions of the Committee be extended to include the liquid trade refuse from all manufactories (if any) which the Medical Officer of Health is of opinion would unduly interfere with the purification of the sewage, or which would tend to produce an effluent injurious to agriculture if applied thereto, or which would create a nuisance in the sewers injurious to health, or would be calculated to damage the structure of the sewer:—

That the liquid trade refuse from tanneries and leather works be permitted to be discharged into the public sewers on the conditions:—1. That an examination shaft be built in each manufactory over the drain discharging into the sewer, of such dimensions and in a manner to enable the Medical Officer of Health to take samples from the passing liquid refuse whenever he may desire to do so. 2. That the exercise of this permission be only commenced and continued after the Medical Officer of Health shall have certified that such shaft has been built to his satisfaction, and that the works for preliminary depuration of the liquid refuse, if any, have been made, brought into operation, and be continued to his satisfaction. That no certificate be issued by the Medical Officer of Health in accordance with the previous resolution, without the sanction of the chairman or deputy-chairman of this Committee.

It was also decided that, in addition to the foregoing, the following conditions be imposed:—

That, wherever required by the Medical Officer of Health, works for the preliminary depuration of liquid refuse be carried out by the manufacturers. That the liquid refuse from all breweries, in addition to being subject to the foregoing requirements and to those of the Medical Officer of Health, shall be passed through a sieve of  $\frac{1}{2}$  of an inch mesh, to be provided by the owner or occupier of the premises.

## THE IMPORTATION OF CHEMICAL PRODUCTS INTO PORTUGAL.

*Pharm. J., July 3, 1897, 18.*

The importation of chemical products into Portugal during 1895 as compared with the value in 1894 was as follows, the percentages showing the increase:—Pyrologi-

neous acid, 1,000*l.* (107 per cent.); arsenious acid, 250*l.* (79 per cent.); muriatic acid, 2,800*l.* (170 per cent.); nitrate of potash, 10,800*l.* (23 per cent.); nitrate of soda, 5,100*l.* (40 per cent.); iodine, 580*l.* (15 per cent.); phosphorus, 1,300*l.* (97 per cent.); refined carbonate of potash, 1,580*l.* (76 per cent.); unrefined carbonate of potash, 484*l.* (53 per cent.); carbonate of soda, unrefined, 340*l.* (44 per cent.); chloride of sodium, 1,009*l.* (79 per cent.); sulphate of soda, 1,920*l.* (45 per cent.); sulphate of potash, 520*l.* (1,826 per cent.); sulphate of iron, 1,360*l.* (870 per cent.); sundries unspecified, 55,600*l.* (6 per cent.). Nitrate of silver, 620*l.*, is nearly the same as previous year, and the same in the case of the value of sulphate of copper imported, 36,920*l.*, although the quantity decreased by some 500 tons. The following show a decrease:—Sulphuric acid, 79*l.* (41 per cent.); borate of soda, 355*l.* (51 per cent.); carbonate of soda, dry, 11,900*l.* (9 per cent.); chloride of lime, 4,200*l.* (27 per cent.); salts of quinine, 1,700*l.* (27 per cent.).

## CARBIDE OF CALCIUM AND THE PETROLEUM ACTS.

In view of the growing importance of the manufacture and the use of carbide of calcium for illuminating purposes, it was considered desirable by the State authorities to promulgate certain regulations with regard to its sale and storage, which were formally specified in an Order in Council, dated February of this year.

The regulations appear to be founded very largely upon the Petroleum Acts, 1871–81, but as the regulations referred to in this connection might be considered as not sufficiently explicit without further definition, the Acetylene Illuminating Company, manufacturers of carbide of calcium at the Falls of Foyers, have issued a pamphlet which contains an abstract of both the Petroleum Acts and the regulations of the London County Council applicable to the storage of carbide of calcium.

It is pointed out in the preliminary observations made by the Acetylene Illuminating Company that it is optional for all local authorities to modify the suggestions made by the London County Council in any manner they may think desirable.

The Acetylene Illuminating Company, for some months past, have been in correspondence with the Home Office. We have it upon their authority that the Home Office are anxious to avoid any measures which might result in an obstruction to the new industry, at the same time entertaining a careful and proper regard for the public safety.

## BOARD OF TRADE RETURNS.

## SUMMARY OF IMPORTS.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised are accepted as open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

11,387. F. C. Roberts. Improvements in furnace tuyères. June 14.

14,106. A. J. Boulton.—From A. Vandenberghe, Belgium. Improvements in or relating to apparatus for the manufacture of acetylene, sulphuretted hydrogen, carbonic acid, and other gases.

14,408. A. J. Boulton.—From F. Württemberg, Italy. Improvements in or relating to regenerative furnaces. Complete Specification. June 14.

14,539. J. H. R. Dinsmore. Improvements in and connected with thermometers. June 16.

14,778. H. Mawhood. A new system of reverberatory furnace, with retorts for calcining divers products. June 18.

14,896. F. H. Adlis. Improvements in or connected with apparatus for cooling air. June 19.

14,933. R. Kurka. Improvements in or relating to filters. June 19.

15,105. S. C. Davidson. Improvements in apparatus for drying, or partially drying, or otherwise treating tea leaf, tobacco leaf, coffee, grain, malt, wool, and other substances. June 23.

15,106. S. C. Davidson. Improvements in apparatus for the drying or other treatment of tea leaf, tobacco leaf, coffee, grain, malt, fruits, and other substances. June 23.

15,107. S. C. Davidson. Improvements in apparatus for applying aqueous vapour, or moist air, or gases to substances, especially applicable for softening, limping, or withering tea leaf, moistening or "ordering" tobacco leaf, or for similar treatment of other analogous substances. June 23.

15,117. J. H. Bowley. Improvements in apparatus for controlling atmospheric conditions. Complete Specification. June 24.

15,223. E. Pamphilon, H. J. R. Pamphilon, and E. Wright. Improvements in triturating apparatus. June 25.

15,231. A. Huillard. An improved mode of and apparatus for desiccating various substances. June 25. Date applied for Jan. 7, 1897, being date of application in France.

15,341. W. J. Baker. Improvements in and relating to apparatus for purifying water and steam, and for heating and softening water. June 28.

15,402. E. Sterné. See Class II.

15,529. G. C. Henning. Recording or indicating apparatus for testing materials. Complete Specification. June 29.

15,740. J. R. Green. Improvements in non-conducting coverings for boilers, pipes, and for other purposes. July 2.

15,917. J. R. Green. Improvements in non-conducting coverings for boilers, pipes, and for other purposes. July 5.

16,035. A. J. Boulton.—From A. G. Waterhouse and A. W. Case, United States. Improvements in or relating to heating fluids and distilling. Complete Specification. July 6.

16,237. P. Gerlach. Improved cooling apparatus for beer and other liquids. Complete Specification. July 8.

16,398. R. Hadden.—From H. Colberg, A. Serret, and F. Amigo. An improved furnace for the production of carbide of calcium. Complete Specification. July 10.

16,454. R. D. Bailey and L. P. Ford. See Class XVII.

16,513. R. T. Hewlett. An improved apparatus for scalding, pasteurising, or sterilising milk or other fluids. July 13.

16,787. W. Lockwood. An improved method of generating steam and other vapours. July 15.

16,836. J. Johnson. Worm liquor cooler and refrigerator. July 16.

## COMPLETE SPECIFICATIONS ACCEPTED \*

## 1896.

10,763. F. Svoboda. Improvements in and connected with Siemens' regenerative furnaces. June 30.

15,671. W. Waddell and D. Waddell. See Class XI.

15,721. W. H. Watkinson. Improvements in steam boilers and in vessels for heating and cooling fluids. June 23.

16,555. N. McG. Greaves. Improvements in appliances for the prevention of smoke from furnaces. July 14.

17,530. G. Helps. Improvements in and relating to regenerative furnaces for heating gas retorts and the like. June 30.

18,137. J. L. Dobell. Improvements in means or apparatus for condensing nitrous acid or other fumes or vapour. July 14.

18,377. C. W. Ramstedt. Improvements in apparatus for heating or cooling liquids. July 14.

19,297. W. R. Lake. From R. Spasciani. Improvements in carbons, demijohns, and the like. July 21.

19,800. T. Preece and A. Preece. Improvements in combined self-producing gas furnaces and muffles for use in enamelling metallic articles. July 14.

20,134. L. F. Hauptman. Improvements in apparatus for clarifying saccharine solutions. June 30.

27,477. J. Grossé. See Class XVII.

27,989. F. M. Ashley. Improvements in sterilising apparatus. July 7.

28,718. T. Tennessy. Improvements in and relating to gas generators. July 7.

29,858. F. Altmann. Improved method and apparatus for burning liquid fuel. June 23.

## 1897.

7888. E. Fournier. Improvements in or relating to apparatus for use in sterilising, disinfecting, and similar purposes. July 14.

8456. J. Muir, E. A. Moré, and F. O. Pierson. Refrigerating apparatus. June 23.

9582. S. H. Johnson. Filter presses. July 21.

10,867. A. Ehrhardt. Linoleum drying and oxidising apparatus. June 30.

11,700. E. Simoneton. Apparatus for filtering liquids. July 21.

14,226. L. Lewis. Composition for preventing incrustation in steam boilers. July 21.

## II.—FUEL, GAS, AND LIGHT.

## APPLICATIONS.

- 14,368. E. E. Probert.—From A. C. Niermeyer, Holland. Improvements in incandescent gas lamps or lanterns principally intended for street use. Complete Specification. June 14.
- 14,401. G. F. Redfern.—From J. Martin, Victoria. Improved means for supplying vaporised liquid fuel at high temperatures to steam boiler and other furnaces. June 14.
- 14,406. A. J. Boulton.—From A. Vandenberghe, Belgium. See Class I.
- 14,471. H. A. Jones. Improvements in gas apparatus. Complete Specification. June 15.
- 14,499. J. C. J. Steinbach. Improvements in and relating to mantles and the like for incandescent gas burners. Complete Specification. June 15.
- 14,505. H. H. Lake.—From the firm Piatti and Co., Italy. Improvements in the manufacture of illuminating gas. June 15.
- 14,535. T. Watkins. Improvements in oil or spirit vaporising apparatus. June 16.
- 14,555. C. C. Smith. Improvements in acetylene gas generators. June 16.
- 14,558. J. A. Murray and G. Davis. Improved candle wick. June 16.
- 14,594. J. B. I. Julhe. Improvements in the means or apparatus for supplying and burning petroleum or other inflammable liquids for illuminating purposes. June 16. Date applied for March 24, 1897, being date of application in France.
- 14,598. J. Heathcock. A new or improved manufacture of briquette fuel. Complete Specification. June 16.
- 14,689. N. Lejeune. Improvements in acetylene gas producers. June 17.
- 14,700. H. R. Bean and H. Ringwood. An improved purifier and enricher for acetylene gas. June 17.
- 14,742. T. R. Fowler. Improvements in and appertaining to apparatus for the manufacture of acetylene gas. June 18.
- 14,822. W. B. Smith. Improvements in refractive substances to be heated by gas, including oxyhydrogen, for illuminating. June 18.
- 14,835. G. W. Gaskell and R. F. Reeve. A new or improved acetylene gaslight apparatus applicable for use in photographic studios for photographing at night. June 18.
- 14,844. S. Pitt.—From The Compagnie Internationale des Procédés A. Seigle, France. Apparatus for heating by means of liquid hydrocarbons. Complete Specification. June 18.
- 14,890. W. Hutchinson. Improvements in and relating to incandescence gas burners. June 19.
- 14,905. H. Sefton-Jones.—From P. P. H. Macé, France. Improvements in or relating to the production of acetylene gas. June 19.
- 14,929. A. J. B. Lége and A. D. Pennellier. Improvements in or connected with the production and burning of acetylene gas. June 19.
- 15,060. C. Kaestner. Improvements in or relating to acetylene gas burners. June 23.
- 15,125. J. W. Searth. Improved apparatus for the generation of acetylene gas and the like purposes. June 24.
- 15,261. E. Altmann. Improvements in apparatus for generating a vaporous or gaseous mixture from hydrocarbon containing liquid and water, for the production of a blue flame. June 25.
- 15,317. M. Graetz. Improvements in oil-burners for the production of non-luminous flames, especially for heating incandescent bodies. June 26.
- 15,350. A. Zendroni. Improvements in the manufacture of artificial fuel or briquettes. June 26.
- 15,369. E. F. J. C. Bauweraerts. Improvements relating to the carbureting of illuminating gas, and to apparatus therefor. Complete Specification. June 26.
- 15,402. E. Sterné. Improvements in capsules or containers for containing compressed or liquefied gases. June 28.
- 15,483. B. Baron. See Class XXII.
- 15,509. L. V. Pratis and P. Marengo. Improvements in and connected with, and apparatus for the manufacture or production of, hydrogen gas. Complete Specification. June 29.
- 15,558. F. Crabb and E. W. Hampton. Improved incandescent lamp. June 30.
- 15,657. W. T. McGarry. Converting peat into coal. July 1.
- 15,754. F. H. Smith. Improvements in acetylene gas generators. July 2.
- 15,813. E. Andreoli. Improvements in and connected with the manufacture or production of ozone, and in apparatus therefor. July 2.
- 15,900. E. Soxhlet, F. Van den Berge, A. Borremann, and V. Borremann. An improved lighting and heating gas, and means for producing the same. July 3.
- 15,963. A. Kiesewalter. Improvements in incandescence mantles. Complete Specification. July 5.
- 15,966. A. Salomon and J. Jacquin. Improvements in apparatus for the generation of acetylene gas. July 5.
- 16,029. P. Pascal. Improvements in and apparatus for the manufacture or production of ozone. July 6.
- 16,132. F. Stadelmann and Co., Ltd.—From K. Thurnauer, Germany. Improvements in acetylene gas burners. July 7.
- 16,145. A. George. Improvements in the manufacture of briquette fuel. Date applied for Feb. 20, 1897, being date of application in France. Complete Specification. July 7.
- 16,344. J. Ackroyd and B. Ackroyd. Improvements in apparatus for making acetylene gas. July 10.
- 16,751. J. Stevenson. An improved washer for extracting ammonia liquid. July 15.
- 16,793. O. V. Sigurdsson. Improvements in means employed in the manufacture of acetylene gas. July 15.
- 16,890. R. H. Whiteley and W. Ellis. Improvements in the method of and apparatus for enriching coal gas. July 16.
- 16,975. G. C. Marks.—From A. F. Bowers, France. Improvements in apparatus for the generation of acetylene gas. Complete Specification. July 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896

- 15,671. W. Waddell and D. Waddell. Assisting combustion, preventing smoke, and economising fuel, and in the means employed therefor. June 30.
- 17,038. L. T. FitzGibbon. Improvements in and connected with apparatus for generating and storing acetylene gas. July 7.
- 17,198. B. Grau. Improvements in coking ovens. July 7.
- 17,605. W. H. Wheatley.—From C. Schmid. Improvements in the manufacture of incandescence bodies for illuminating purposes. July 14.
- 17,646. M. Duffield. An improved acetylene gas generator. July 21.
- 17,678. A. C. Fraser. Improvements in process and apparatus for generating and liquefying acetylene. Filed Aug. 10. Date applied for Feb. 21, 1896, being date of application in United States. June 23.
- 17,778. B. T. L. Thomson. Improved means for producing carbonic acid and hydrogen gases. June 23.
- 18,819. W. Clark.—From A. Meyenberg, M. Wendorf, and S. Henlein. Improvements in incandescent lamps for the combustion of petroleum. July 14.
- 18,992. E. Chesnay and L. Pillion. Improvements in apparatus for generating, storing, and delivering acetylene gas. Filed Aug. 27. Date applied for Jan. 31, 1896, being date of application in France. June 30.

19,059. W. P. Thompson.—From D. H. Chivert, France. Improvements in or appertaining to the production of acetylene gas, and apparatus therefor. July 7.

19,126. G. Voigt. Improvements in apparatus for producing acetylene gas. June 30.

19,353. G. Kremer. Improvements in the production, by the cold process, of gas for lighting and motive power, and apparatus therefor. July 21.

20,238. H. Turner and W. Allen. Improvements in or applicable to smoke-burning apparatus. July 14.

20,406. P. Trost. Improvements in acetylene gas lamps. July 7.

20,694. W. P. Thompson.—From V. I. Comucci. Improvements in apparatus for generating and storing acetylene gas. July 21.

22,628. E. A. Morten Brown and E. Mawndrell. Improved apparatus for production and storage of acetylene gas. July 7.

26,784. R. Moll and A. Palmer. A new or improved method of manufacturing incandescent mantles and caps for gas and other burners. July 7.

1897.

1398. W. R. Addicks. Improvements in the manufacture of carburetted water-gas and in apparatus therefor. July 14.

4870. E. J. Frost and B. Middleditch. Improvements in devices for automatically regulating the quality of gas. July 7.

8989. J. G. Kerr and C. Fry. Improved apparatus for the production and storage of acetylene gas. July 7.

10,371. A. A. Stevenson. Composition for making gas. June 23.

11,130. A. C. Humphreys and A. G. Glasgow. Apparatus for making carburetted water-gas. July 21.

11,131. A. C. Humphreys and A. G. Glasgow. Apparatus for making carburetted water-gas. July 14.

11,252. F. van den Abeele. Automatic apparatus for supplying incandescent gas burners with gas under pressure. July 14.

12,096. L. J. Davies. Process for making coke from anthracite and similar coal. July 7.

12,556. R. Guatanneus-Moenus and E. Carreer-Dilger. Improved automatic apparatus for the production of acetylene gas. June 30.

13,496. F. A. Mitchell. Acetylene gas generators. July 7.

14,015. F. Trendel. Apparatus for producing acetylene gas. July 21.

14,368. E. E. Probert.—From A. C. Mirmeyer. Improvements in incandescent gas lamps or lanterns principally intended for street use. July 21.

14,499. J. C. J. Steinbach. Mantles and the like for incandescent gas burners. July 21.

14,598. J. Heathcock. Manufacture of briquette fuel. July 21.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### APPLICATION.

15,517. M. Ziegler. Improved process of and apparatus for carbonising peat, lignite, and the like, and the recovery of by-products therefrom. June 29.

#### COMPLETE SPECIFICATION ACCEPTED.

1897.

10,577. G. C. Marks.—From La Compagnie pour la Fabrication des Compteurs et Matériels d'Usines à Gaz. Triple-action apparatus for the recovery of benzols and other products contained in certain gases.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

14,375. H. Imray.—From F. Hoffmann and La Roche and Co., Switzerland. Manufacture of phenetidine-sulphonic acid and its salts, as also of acetyl derivatives of the latter. Complete Specification. 14 June.

14,376. H. Imray.—From F. Hoffmann and La Roche and Co., Switzerland. Manufacture of sulphonic acids of guaiacol and of cresote, and of metallic salts of these sulphonic acids. June 14.

14,917. M. Otto. Improvements in the manufacture of colouring or carbouol matters. June 19.

14,918. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of black colouring matters of the anthraquinone series. June 19.

14,919. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of yellow colouring matters from benzoïn. June 19.

14,920. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of asymmetric diamidophenyl acridines and their alkyl substitution products. June 19.

14,921. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of green mordant-dyeing colouring matters from halogen substituted fluoresceines. June 19.

15,009. R. Barge. Process for separating ortho-anhydrosulphamine-benzoic acid from para-sulphamine-benzoic acid. Complete Specification. June 21.

15,290. W. McCowan. Improvements in the manufacture of colouring matter. June 26.

15,353. S. Pitt.—From L. Cassella and Co., Germany. Producing diazo salts in a durable form. June 26.

15,377. W. H. Claus, A. Rée, and L. Marchlewski. Production of new polyazo colouring matters. June 28.

15,478. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of dyestuffs. June 29.

15,479. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring matters. June 29.

15,587. H. Koechlin. Improvements in treating paranitraniline reds and analogous colours, when applied on vegetable fibres or silk, to render them fast to light. June 30.

15,630. A. Ashworth. Improvements in the manufacture and production of colouring matters suitable for dyeing unordanted cotton. June 30.

15,890. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of ortho- and para-nitrobenzylamine sulphonic acids and their homologues. July 3.

16,396. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of methylphenmorpholine. July 9.

16,483. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of dyestuffs of the triphenylmethane series fast to alkali. July 12.

16,495. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of blue mordant-dyeing colouring matters from dinitro-anthraquinones. July 12.

16,496. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of new colouring matters for animal fibre. July 12.

16,713. M. Prud'homme. Manufacture of colouring matters having acid action. July 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

13,093. H. R. Vidal. Manufacture of dyes. Date applied for June 3, 1896, being date of application in France. July 21.

14,931. G. B. Ellis.—From La Société Chimique des Usines du Rhone, anciennement G. P. Monnet et Cartier. Manufacture of pyrocathechin-sulphonic acid and intermediate products. June 23.

15,953. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Production of new dyes relating to the oxyphenanthronaphthazine series, and of new intermediate products and materials therefor. June 23.

17,382. C. Uffelmann. Manufacture of a solid paste or soap compound for dyeing all kinds of textile materials. June 23.

18,020. W. H. Claus, A. Rée, and L. Marchlewski. Production of new azo-dyes. June 30.

18,221. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Improvements in the manufacture and production of phthalic and sulpho-phthalic acids. June 23.

19,831. S. Pitt.—From L. Cassella and Co. Production of black colouring matter. July 14.

20,676. O. N. Witt. Manufacture of derivatives of para-amido-alpha-naphthol and of colouring matter therefrom. July 21.

21,437. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of a new black mordant-dyeing colouring matter. July 14.

1897.

12,180. H. Inray.—From The Chemical Works Bind-schedler. Obtaining new dyestuffs of the phthaleine series. June 23.

12,181. H. Inray.—From The Basle Chemical Works Bind-schedler. Process for obtaining new dyestuffs of the phthaleine series. June 30.

12,964. L. Lederer. Process for the extraction of the hydroxylated ethers of phenol from mixtures. July 21.

14,375. H. Inray.—From F. Hoffmann and La Roche and Co. Manufacture of phenetidine-sulphonic acid and its salts, as also of acetyl derivatives of the latter. July 21.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

### APPLICATIONS.

14,642. E. Knecht. Improvements in lace manufacture. June 17.

14,739. J. W. Knights. The prevention of nuisance in the retting of flax, hemp, or other fibrous plants. June 18.

14,868. J. M. MacDonald and H. H. Boyle. Improvements in the treatment of reed grass and fibrous plants, and in apparatus therefor. June 19.

14,927. S. H. Sharp. Improved manufacture or treatment of cotton and other fabrics. June 19.

15,381. G. B. Garlach, of the firm of Ketting and Braum. Improvements in the process of and means for finishing or dressing textile fabrics and other goods. June 28.

15,642. C. W. Radeke. Improvements relating to the treatment of textile vegetable fibres. July 1.

16,518. F. W. Ashton and Co., Ltd., and E. C. Kayser. Improvements in the production of printed textile fabrics. July 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

15,893. J. Waugh.—From Amos and Co. Method of waterproofing fabrics made of fibre, paper-tissues, and the like. June 23.

16,840. E. Edwards.—From F. A. Bernhardt. Improvements in the process of what is known as "mercerising" fabrics composed of vegetable fibres. June 30.

17,841. W. Grimsshaw. Improvements in and in means for ornamenting textile and other fabrics or materials. July 7.

18,360. F. N. Turney. Improvements in apparatus for degreasing wool, cotton waste, and other fibrous materials. June 23.

18,517. W. J. A. Donald. See Class XIII.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

14,639. W. Woodcock, J. Longthorpe, and W. Dargue. Improvements in machinery for dyeing, sizing, and washing banks of yarn and slubbing. June 17.

14,831. M. L. Kellogg. Improvements in dyeing hair or fur. Complete Specification. June 18.

15,198. J. H. Gartside.—From Romann, France. Improvements in bleaching textile fibres, yarns, and fabrics. June 25.

15,293. J. Nelson and A. Nelson. Improvements in the method of and apparatus for dyeing fabrics and otherwise exposing them to the action of liquids. June 26.

15,587. H. Koechlin. See Class IV.

15,913. J. T. Reid and H. Thorp. Improvements in dyeing textile fibres, yarns, and fabrics. July 5.

16,191. J. H. Gartside.—From J. J. Romann, France. Improvements in bleaching vegetable textile fibres, yarns, and fabrics. July 8.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

17,692. C. Dratz. Process and apparatus for printing multicoloured designs upon fabrics and warp chains. July 14.

22,522. A. M. Clark.—From C. H. Boehringer and Sohn. An improved mordanting agent and process for vegetable fibres. July 14.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

14,836. C. C. Moore. Improvements in the treatment of crude borates and in obtaining boracic acid. June 18.

15,976. E. M. Polet. Improved process relating to the treatment and production of phosphates. July 5.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,877. D. Bray. A still or tank for the distillation, boiling, and holding of acids, alkali, and other corrosive liquids. June 30.

17,127. J. C. Graham. Improved process for the preparation and purification of solutions of copper. July 14.

17,607. J. R. Wyld, J. W. Kynaston, and J. Brock. Improvements in the manufacture of hydrochloric acid free from arsenic. June 23.

17,839. H. Brewer. See Class X.

19,222. J. Y. Johnson.—From The Cuemische Fabrik Electron Actien Gesellschaft. Improvements in the treatment of bleaching powder to preserve it from loss of active chlorine. July 21.

1897.

3795. G. G. M. Hardingham.—From T. Huntington and F. Heberlein. See Class X.

13,551. W. Majert. Process for the production of ammonium bichromate. July 21.

## VIII.—GLASS, POTTERY, AND ENAMELS.

### APPLICATIONS.

14,381. J. Gullich. Apparatus for the covering of earthenware, porcelain, or metallic objects with glaze or enamel. June 14.

14,481. C. E. Blue, jun. Improvements in machines for the manufacture of glassware. Complete Specification. June 15.

15,217. E. Gobbe. Improved continuous kiln for baking pottery or burning cements. June 25.

15,618. T. Küpper. Improved apparatus for glass-blowing. Complete Specification. June 30.

16,062. E. F. W. Hirsch. Improvements in glass-melting plant. July 6.

16,435. F. Ohnemüller. Method for printing upon baked-hard porcelain or other earthenware before glazing. July 12.

16,528. W. Cliff. Improvement in or connected with the enamelling of fire-clay baths and other articles. July 13.

16,873. R. Good and R. Good, jun. Improvements in machinery for manufacturing glass vessels. Complete Specification. July 16.

16,883. D. Laffan. Improvements in apparatus for forming, beeking, and annealing glass bottles or other hollow glass-ware. July 16.

16,947. J. T. Szék. Improvements in the manufacture of floor tiles, and the like. July 17.

16,964. W. Thomson. An improved glass tile. July 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,927. T. Hausermann. See Class X.

17,599. H. Sturm. Improvements in continuous ceramic furnaces with heated movable soles. July 7.

19,746. F. Hancock and C. B. Winzer. Apparatus for pottery purposes. July 14.

1897.

8494. L. Mondron. Improvements in the manufacture of plates of glass design for covering walls, ceilings, and other surfaces. July 7.

10,691. P. Delorme Fils. Manufacture of hollow castings of glass and the like, and apparatus therefor. June 23.

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

##### APPLICATIONS.

14,970. J. M. Danielli. Improvements in the imitation of coloured marbles. June 21.

15,050. P. Rückert. Improvements in and connected with artificial stones. Complete Specification. June 23.

15,083. F. D. T. Lehmann and P. N. Kohlsaat. Improvements in fireproof buildings and structures. Complete Specification. June 23.

15,632. E. Marshall Fox. Improvements relating to unflammable wood. June 30.

16,260. E. P. A. Hugues. Improvements in cement building materials. July 9.

16,664. H. H. Lake.—From J. Seidler and A. J. C. Graf, Germany. Improvements in and relating to the manufacture of artificial blocks or plates for building and other purposes. July 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,892. T. R. Jones. An improved process for hardening stone. July 7.

18,295. J. F. Cleine. Improvements in fireproof ceilings and floors. July 7.

19,419. A. McLean. Improvements in artificial stone. July 21.

1897.

8261. J. Howden. Improvements in fireproof floors. July 7.

13,026. W. Chrometzka. Fireproof ceilings. July 7.

14,068. J. A. Fisher. Fireproof ceilings and partitions. July 14.

#### X.—METALLURGY, MINING, Etc.

##### APPLICATIONS.

14,392. C. Wetherwax. Improved method of and means for the preliminary treatment of gold and silver ores. June 14.

14,438. W. G. M. Foote. Improved method of and apparatus for extracting metals from their ores or other compound bodies containing them. Complete Specification. June 15.

14,567. O. Hermann. An improved alloy. June 16.

14,662. A. S. Bower. Improvements in the treatment of spent oxide of iron for obtaining products of commercial value. June 17.

14,693. T. Levoz. Improvements in casting ladles for steel and iron. Complete Specification. June 17.

14,833. J. E. Fairley. Improvements in the process of annealing metals. June 18.

15,115. S. Alley.—From J. Campbell and J. W. H. James, United States. Improvements in furnaces for treating ores containing precious metals and other ores. June 24.

15,203. S. Alley. Improvements in and connected with furnaces for treating ores containing precious metals and other ores. June 25.

15,455. A. E. Thomas. To refine or purify Cleveland or other impure iron (to make it suitable for use in the manufacture of cast-iron work, wrought iron, and wrought and cast steel). June 29.

15,569. T. G. Bowick. Improvements in and relating to the recovery of gold and other precious metals. Complete Specification. June 30.

15,631. T. A. Middleton and H. R. Gregory. Improvements in and connected with the extraction of gold from solutions containing the same. June 30.

15,674. C. Wetherwax. An improved process of treating gold ores. July 1.

15,700. W. Muir. Improvements in the manufacture of potassium and sodium. July 1.

15,742. R. McAlley. New process for the production of cobalt and its oxides from its ores, and of by-products therefrom. July 2.

15,791. N. W. Edwards. A new or improved method of and process for treating antimonial and antimonial gold ores. July 2.

15,999. J. Parry and G. H. Llewellyn. Improvements in the manufacture of iron and steel. July 6.

16,127. S. Curtis and J. E. Chaster. Improvements in the extraction of gold from ores or other substances containing same. July 7.

16,808. F. Ellershausen. Improvements in the treatment of complex sulphide ores and apparatus therefor. Complete Specification. July 15.

16,922. H. J. Kloos. An improved powder for use in welding metals, and process of manufacturing same. July 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

13,565. J. W. Spencer. Face-hardening metals. June 30.

13,641. C. J. Claus, jun. Improvements in or relating to the treatment of tin or antimony ores, and the separation of the gold and silver contained therein. June 23.

14,493. J. Garnier. Processes and apparatus for classifying, amalgamating, and cyanising gold and silver ores. Filed June 30. Date applied for May 7, 1896, being date of application in France. July 7.

14,927. T. Hausermann. Process for dyeing or ornamenting objects of metal, porcelain, or the like. July 7.

16,032. W. H. Hyatt. Improvements in apparatus for separating gold from other materials. July 21.

16,831. W. T. Sugg. Improved metallic alloy. July 7.

17,299. E. F. Turner. An improved process for the treatment of zinciferous ores. June 30.

17,839. H. Brewer. Improvements in and relating to the treatment of zinc ores or ore residues in the production of zinc, chlorine, sodium sulphate, and other products. June 23.

18,616. J. Legge. Improvements in puddling and other like furnaces. June 30.

19,178. J. Shanks. Improvements in moulds for casting. July 7.

19,140. J. Lones and E. Holden. An improvement or improvements in the manufacture of buffer-iron or steel for buffer-barrels or cylinders of railway carriages, trucks, and waggon. June 30.

19,640. W. van Wert, F. W. Poop, and J. J. Bradley. Improvements for producing certain kinds of metal, especially adapted for use in the manufacture of the tubes and other of the component parts of cycles of all kinds, autocars, and other wheeled vehicles, which improvements are also applicable for other industrial purposes. July 11.

19,718. G. Bennett. Improvements in ingot moulds for the casting of ingots of iron, steel, or other metals, such as iron or steel alloys. July 7.

20,131. W. Roberts. Improvements in the machinery or appliances for the manufacture of plates and sheets of copper, brass, and German silver. July 14.

24,657. R. F. Strong. Improvements in the treatment of ores for the production of iron, steel, and other metals. June 30.

#### 1897.

3795. S. G. M. Hardington.—From T. Huntington and F. Herberlein. Improvements in the treatment of sulphide ores of lead preparatory to smelting the same, and incidentally in obtaining sulphurous acid. July 7.

8376. G. Kentler and F. Steinert. Process and apparatus for recovering iron for slag-heaps. June 23.

8873. W. Noad and W. Agate. Improvement in the obtainment of copper from ores and other copper-bearing substances. May 19.

14,693. T. Levoz. Casting ladles for steel and iron. July 21.

### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

#### APPLICATIONS.

14,508. I. Kitsée. Improvements in primary batteries or cells. Complete Specification. June 15.

14,708. G. H. Nash. Improvements in apparatus for coating metal articles by electro-deposition. June 17.

14,709. G. H. Nash. Improvements in apparatus for coating metal articles by electro-deposition. June 17.

15,013. S. Pitt.—From L. Bomel and Société Bisson, Bergès, et Cie., France. Negative electrode for zinc accumulators. Complete Specification. June 21.

15,047. A. Heinemann and W. Schäfer. Improvements in and relating to electric accumulators or storage batteries. June 23.

15,080. A. J. Boulton.—From J. Trillet, France. Improvements in or relating to electric batteries. June 23.

15,090. H. C. Carter. Improvements in electric accumulators. June 23.

15,222. L. Fiedler. Improvements in and relating to electric accumulators. June 25.

15,323. A. Heil. Improvements in electrical accumulators. June 26.

15,510. J. Y. Johnston.—From J. P. Clare, G. E. Hatch, J. H. Taylor, United States. Improvements in secondary or storage batteries or accumulators and in the manufacture of the same. Complete Specification. June 29.

15,513. C. A. Jensen.—From P. Jelsén, Norway. Process for producing peat charcoal by means of an electrical current. Complete Specification. June 29.

15,850. J. B. Brooks and J. Holt. Improvements in certain apparatus to be employed in connection with the electro-deposition of metals. July 3.

15,879. W. J. S. Barber-Starkey. Improvements in and relating to plates for secondary batteries. July 3.

15,903. A. D. Seton and J. L. Dobell. Improvements in or connected with electric batteries. July 3.

15,939. E. A. Jahneke. Improvements in the manufacture of protective coverings or envelopes for zinc plates of electric batteries and for other purposes. July 5.

15,941. E. A. Jahneke. Improvements in or connected with electric batteries. July 5.

16,069. L. W. Pullen. Improvements in electric batteries. Complete Specification. July 6.

16,361. E. W. Jungner. Improvements in or relating to accumulator plates for secondary batteries. Complete Specification. July 10.

16,362. E. W. Jungner. Improvements in or relating to the electrodes of electric accumulators. Complete Specification. July 10.

16,665. C. Therye. Improvements in electric batteries. July 13.

16,797. G. J. Erlacher and M. A. Besso. Improved controlling apparatus for accumulator batteries. July 15.

16,816. H. Leitner. Improvements in the construction of secondary batteries. July 15.

16,942. C. Bertolus. An electric furnace for the application of polyphase currents in processes of fusion or decomposition by means of the voltaic arc. Complete Specification. July 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### 1826.

7222. A. S. Elmore.—From J. O. S. Elmore. Apparatus for manufacturing tubes by electrolytic deposit. July 14.

13,688. A. E. Bonna, A. Le Roger, and P. van Berchen. Apparatus for the treatment of air, gases, and vapours. June 23.

16,057. C. Kellner. Improvements in electrolytic apparatus. July 7.

17,608. The Cowper-Coles Galvanising Syndicate, Ltd., and S. O. Cowper-Coles. Improvements in means or apparatus for effecting the electro-deposition of zinc or other metals upon tubes or other circular or analogous objects. July 14.

17,671. L. Hoepfner. An improved method for obtaining porous metals by electrolysis. June 23.

19,308. W. Walker, jun., F. R. Wilkins, J. Lones, and J. Lones. Improvements in utilising the residual products obtained in the working of certain kinds of voltaic batteries. July 14.

25,365. H. Woodward. An improved electrode for secondary batteries. July 7.

### XII.—FATS, OILS, AND SOAP.

#### APPLICATIONS.

15,156. A. Jolles. A new manufacture of soaps and process therefor. Complete Specification. June 24.

15,927. W. Smith and J. E. T. Woods. Improvements in the purification and conversion of certain residual hydrocarbon oils produced in the making of camphor substitutes into oils suitable as disinfectants, and for other useful purposes. July 5.

15,972. C. Romen. Process for producing a disinfecting, deodorising, and bleaching soap powder. July 5.

16,382. F. Becker and O. Wolff. Improvements in the manufacture of soaps or cleansing compositions. July 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### 1896.

14,308. A. Schuchardt and T. Otto. New washing substance and process for making it. July 7.

15,336. T. Coad. Improved treatment of fat or fatty waste. July 21.

1897.

13,507. I. Kohn and M. Kohn. Transparent soap blocks or tablets containing inscriptions. July 14.

### XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

#### APPLICATIONS.

14,439. H. Edmunds. Improvements in the manufacture or production of an insulating material, and the application thereof to the insulation of electrical conductors. June 13.

14,911. P. Reidel and E. Kuhn. Improvements in the manufacture of a compound or material applicable for use as a substitute for leather and india-rubber, and for floor coverings and the like, and in apparatus therefor. June 19.

15,180. P. S. Watkins and P. J. Nunn. Improvements in the manufacture of sealing wax. Complete Specification. June 24.

15,269. F. Fenton. Further improvements in the production of artificial india-rubber and gutta-percha-like substances. June 26.

15,330. B. J. B. Mills.—From La Granitine Société Anonyme, Belgium. Process of manufacture of agglutinant enamels. Complete Specification. June 26.

15,678. R. Matthews. An improvement in the manufacture of white lead. July 1.

16,061. M. Greenberg. A liquid tarnish protector for unlacquered metals. July 6.

16,147. S. Rosenblum and S. Rideal. Improvements in the production of chemical compounds from a certain oil or oils, or the fatty acids of same, and the employment of such compounds in the manufacture of drying oils, varnishes, enamels, lacquers, anti-fouling compositions, and the like. July 7.

16,490. J. Stocker and H. Zander. An improved weather acid and fire-resistant material. Complete Specification. July 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,643. C. Day. Improved liquid varnish gum. June 23.

16,276. A. Gutensohn. Improvements in the manufacture of oxide of lead and means used therefor. July 7.

17,078. H. W. Aird and C. E. Felch. Improvements in paint and in method of producing and applying same. June 23.

18,485. W. Mouson. Improvements in acid-proof electrical non-conducting articles and composition therefor. July 21.

18,517. W. J. A. Donald. Improvements in the impregnating of materials with india-rubber, gutta-percha, and the like. July 7.

18,864. D. Forbes and J. S. Weymouth. A gelatinous resilient compound applicable for wheel tyres and other purposes. June 30.

19,046. Siemens Bros. and Co., Ltd., and E. F. A. Oballa. Improved process and apparatus for the extracting of gutta-percha from the leaves and twigs of the *Lonandra Gutta* and kindred plants. July 14.

1897.

5121. J. G. Ingram. Improvements in the manufacture of parti-coloured india-rubber. June 23.

11,500. T. Grantham and J. J. Grantham. Improved boot varnish. July 21.

14,105. F. Boyling, C. L. Garland, and A. Ogden. Enamel paint, and method of applying the same. July 14.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### APPLICATIONS.

15,352. A. Mario. Improvements in or connected with tanning. June 26.

15,404. A. J. Boulton.—From G. Briganlont, France. Improved manufacture of artificial leather or leather substitute. Complete Specification. June 28.

16,477. J. L. Garcin. Improvements in or relating to the manufacture of washable leather or skins. Complete Specification. July 12.

16,804. C. Michel. Improved process and apparatus for the rapid tanning of skins and hides. July 15.

16,927. J. T. McQuinn. Improvements in quick tanning process. July 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,210. W. Clark.—From C. H. Boehringer and Sohn. Improvements in tanning hides and skins. July 7.

21,774. H. Gardner.—From C. W. Suther. Improved manufacture of waterproof glue. June 23.

1897.

13,778. W. Sagar, sen., A. P. Sager, and W. Sager, jun. Apparatus for removing grease or fatty matter from sheepskins and other leather and the like. July 14.

### XV.—AGRICULTURE AND MANURES, Etc.

#### APPLICATION.

14,695. E. Edwards.—From C. J. R. Le Mesurier, Ceylon. An improved manure. June 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

17,151. C. Fell. The natural fertiliser. July 21.

1897.

13,811. I. Kovacs. Process for making a consistent friable artificial manure. July 14.

### XVI.—SUGARS, STARCHES, GUMS, Etc.

#### APPLICATIONS.

14,647. H. W. Aitken. Improvements in sugar-cane mills. June 17.

15,144. J. G. Boers. Improvements in means and apparatus for depositing or crystallising sugar or other substances upon confections or other articles. June 24.

15,295. L. P. Bauer. Improvements in the manufacture of glucose or sugar. Complete Specification. June 26.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

20,434. L. F. Hauptman. Improvements in apparatus for clarifying saccharine solutions. June 30.

1897.

11,842. Z. Lubinski and R. Krajewski. Centrifugal machines for use in the manufacture of sugar. July 7.

### XVII.—BREWING, WINES, SPIRITS, Etc.

#### APPLICATIONS.

14,454. B. J. Atterbury. Improvements in the manufacture of alcohol and in apparatus therefor. June 15.

15,200. A. Fraser and MacLay and Co., Ltd. Improvements in or relating to the manufacture of pale ale. June 25.

15,825. G. Pütz. Improvements in or relating to the clarifying or fining of worts and apparatus therefor. Complete Specification. July 2.

16,232. H. Hempel. A process for producing a carbonaceous agent for enriching spirit. Complete Specification. July 8.

16,454. R. D. Bailey and L. P. Ford. An improved false bottom for the mash tuns, conversion vessels, hop backs, and malt and hop kiln floors found in breweries, distilleries, malt houses, hop factories, glucose manufactories, and vinegar works. July 12.

16,503. A. J. Boulé.—From P. E. Paulet, France. Improved process for the rectification of wines, spirits, and other alcoholic liquors. July 12.

16,609. W. B. Turner. Improvements in the treatment or preparation of malt, corn, or grain for brewing or other purposes. July 13.

16,836. J. Johnson. See Class I.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

19,245. A. C. Field. Improvements relating to malting. July 7.

19,616. K. Pattermann. Improvements in or connected with germination of barley, and apparatus therefor. July 7.

27,477. J. Grossé. An improved evaporating or vacuum apparatus for the granulation of crystallisable liquids. July 14.

1897.

4926. C. Ameye. A machine for aerating wine, beer, and other fermented and unfermented liquids. June 30.

6463. F. W. H. Hempel. Process for producing luminous spirit. June 23.

14,106. N. Bendixen. Propagating apparatus for developing pure culture of yeast and bacteria. July 21.

**XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.**

**APPLICATIONS.**

**A.—Foods.**

14,522. J. E. Lyndall. A new food or food ingredient. June 15.

14,621. R. Hadden.—From A. Many, France. Improvements in the process of preserving food. June 16.

15,145. T. Hill-Jones. The manufacture of a new alimentary extract. Complete Specification. June 24.

15,884. L. Michon and M. F. Gouliet. An improved process or method of preserving alimentary products. Complete Specification. July 3.

16,088. W. Horlick. Improvements in edible and soluble tablets, and method of producing the same. Complete Specification. July 6.

16,154. J. A. Parker. An improved method of preserving fruit, eggs, and other perishable articles. July 7.

16,338. E. Wadham. A new or improved medicinal and nutritive compound or preparation. July 10.

16,586. J. Hogarth. Improvements in and relating to the treatment of alimentary substances and beverages. July 13.

16,930. F. A. Furlonge. An improved process for preserving fresh meat or produce for transport. July 17.

**B.—Sanitation.**

14,895. J. O. Braithwaite. Improvements relating to the purification of water. June 19.

16,103. E. W. Ives. An improved method of extracting the precipitated sludge from the bottom of flat-bottomed tanks used in the purification of sewage and manufacturers' waste waters. July 7.

16,925. C. G. T. Dixon, J. Phythian, and F. F. Bennett. Improvements in the treating of town refuse in destructors, and manufacturing certain by-products therefrom. July 17.

**C.—Disinfectants.**

**APPLICATIONS.**

15,927. W. Smith and J. E. T. Woods. See Class XII.

15,972. C. Roman. Process for producing a disinfecting, deodorising, and bleaching soap powder. July 5.

**COMPLETE SPECIFICATIONS ACCEPTED.**

**A.—Foods.**

1896.

9908. M. P. Hatschek. Production of compressed baker's yeast. July 11.

16,016. A. Backhaus. An improved treatment of the milk of cows or other domesticated animals to render it suitable as food for infants and children. June 23.

19,675. J. E. Duke. Improvements in the manufacture of liquid extracts of coffee or other substances and in apparatus for the purpose. July 17.

1897.

6915. K. I. O'Doherty. Improved method of preventing the decomposition of animal, vegetable, or other alimentary substances or products. Filed March 16. Date applied for Aug. 27, 1896, being date of application in Queensland.

8586. T. Hyatt. Improvements in the treatment and utilisation of chicory. June 23.

16,873. W. T. Murray. Process for preserving milk. July 21.

**B.—Sanitation.**

1896.

16,078. J. Royston. An improved mode of treating night-soil. June 23.

1897.

3830. B. Iribarnegaray. An improved process for use in preserving butter and other food-stuffs. July 7.

**XIX.—PAPER, PASTEBOARD, ETC.**

**APPLICATIONS.**

15,601. A. Von Feszty. Improvements relating to the production of paper pulp from peat. June 30.

15,797. K. A. Zschörner. Manufacture of a fibrous material suitable for making paper from peat. July 2.

16,315. H. Schulte. An improved process of and apparatus for incorporating dissolved and suspended substances into paper, cardboard, or pasteboard in long sieve or cylinder machines. Complete Specification. July 9.

**XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.**

**APPLICATIONS.**

14,610. B. Willeox.—From C. F. Boehringer and Soehne, Germany. Improvements in the manufacture or preparation of theobromine. Complete Specification. June 16.

14,611. B. Willeox.—From C. F. Boehringer and Soehne, Germany. Improvements in the manufacture or preparation of iso-eugenol and derivatives thereof. Complete Specification. June 16.

14,612. B. Willeox.—From C. F. Boehringer and Soehne, Germany. A process for the production of trichloropurine. Complete Specification. June 16.

14,613. A. Verley. Improvements in the manufacture and production of perfumes. June 16.

15,093. A. M. Clark.—From V. Kaufmann, Germany. Process for the manufacture of soluble compounds of vegetable globulins. June 23.

**COMPLETE SPECIFICATIONS ACCEPTED.**

1896.

14,954. C. Goldschmidt. The preparation of a condensation product from vanilline and para-phenetidine. June 23.

18,035. O. Haray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Improved manufacture of oxy-camphor. June 23.

1897.

9701. E. Dolle. Manufacture of improved preparations of iron for medicinal purposes.

12,399. S. Smithson. Machinery or apparatus for treating myrobolams for obtaining extracts therefrom. June 23.

**XXI.—PHOTOGRAPHY.**

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,495. W. S. Wain. Improvements in dishes or baths employed in developing and like photographic and chemical operations. July 21.

1897.

12,922. T. C. Porter. Sensitive plate or film, and method of producing, developing, fixing, and toning the same. July 21.

**XXII.—EXPLOSIVES, MATCHES, Etc**

APPLICATIONS.

14,690. A. Liedbeck. Improvements in the manufacture of nitrocellulose. Complete Specification. June 17.

14,989. J. T. Maguire.—From The Diamond Match Company, United States. Improvements in matches. Complete Specification. June 21.

15,483. B. Baron. Improvements in matches, candles, and the like, and in the method of manufacturing same. June 29.

15,499. H. Maxim. Improvements in the manufacture of explosive compounds. Complete Specification. June 29.

15,693. F. G. du Pont. Improvements in and relating to process and apparatus for treating gun-cotton and other purposes. Complete Specification. July 1.

16,206. G. de Wolf.—From B. C. Pettingell, Canada. A new explosive. July 8.

16,777. J. Macnab. Improvements in blasting and blasting cartridges. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,858. H. Maxim. Improvements in the manufacture of pyroxylin smokeless explosives and in apparatus therefor. July 7.

1897.

4672. L. Roux. Improvements in the preparation of explosives. July 7.

10,362. O. F. Carlson. Explosives. July 7.

13,522. W. Majert. Explosive compound. July 7.

14,690. A. Liedbeck. Manufacture of nitrocellulose. July 21.

**PATENT UNCLASSIFIABLE.**

APPLICATION.

15,170. W. P. Thompson.—From M. Rosenbaum, Germany. Improvements in or relating to the production of porous substances. June 24.

### NOTICES.

#### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, part of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List.	Each copy 10s.
To Subscribers .....	12s. 6d.
To others .....	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

PROF. C. F. CHANDLER IN THE CHAIR.

#### A NEW PETROLEUM WELSBACH LAMP.

BY C. K. MUNN.

THE Washington light, although a new thing in America, is in extensive use in Europe. The two most prominent places illuminated by it are the Boulevard Haussmann in Paris and the Grand Place in Brussels. It is also in use in Spain, Italy, Russia, and Portugal.

The plant consists of a tank or reservoir for holding oil, a copper tube for conducting the oil to the lamp, and the lamp itself. The tank has three openings, one for filling, one for pumping air in upon the oil for the purpose of forcing the oil out of the tank, and a third through which the oil leaves the tank. If desired, a pressure gauge may also be added. The tube, through which the oil is forced, is enlarged inside the tank and contains a filter, consisting simply of waste sufficient only to retard any solid matter in the oil. However, the ordinary kerosene used is comparatively pure, and this filter plays but a small part.

The pressure necessary to force the oil to the lamp at the consumption rate is 49 lb. per square inch, but, by raising it to 55 lb., it in no way affects the burning of the lamp and allows 15 lb. through which the pressure may drop. A few strokes of the pump once a day with this tank is sufficient. The question of constructing tanks, to deliver any quantity of oil for only one pumping, is a question of but little thought. Utilising this drop of pressure, a tank can be constructed which, when once the pressure has been raised to 55 lb., it would not be necessary to again touch until 5 galls. of oil had been consumed. In this lamp this would be after burning 100 hours. For inside lighting, this would mean about 20 days, and for outside lighting about 10 days.

The tube which conducts the oil to the lamp is seamless drawn copper tubing, that used in this case having an outside diameter of  $\frac{3}{8}$  in. and an inside diameter of  $\frac{1}{8}$  in. This tubing is made in four sizes and can be furnished in lengths of from 50 ft. to 100 ft., annealed so that it may be bent around a small diameter without cracking or breaking. The outside diameter of one size is the same as the inside diameter of the next size smaller. This enables us to make joints by simply introducing one size into the next larger size, about one-half an inch, and soldering the joint; or, for joining two pieces of the same size, by using a short piece of the next size larger, and slipping it over both ends and soldering. Tees and crosses are made in

the same way. In the six months the lamp has been burning in our offices in Wall Street I have not experienced the slightest trouble from clogging of the tube, ordinary kerosene being always used. In piping for a number of lamps to be supplied from one tank, it is only necessary to run one large feeder pipe of a larger size and take branches from it to each lamp.

The lamp consists of only three principal parts, viz., the vaporising tube, the mantle supports, and the body of the lamp. The vaporising tube is the tube which passes up in the centre of the lamp, and is so called because the oil is vaporised in it by the heat of the mantles on either side. The small copper tubing leading from the tank enters the vaporising tube near its lower end at the bottom of the lamp. Referring to the drawings, Figs. 1 and 2 show

Fig. 1.

Fig. 2.

sections of the body of the lamp. G is the vaporising tube in which the oil is vaporised. The upper end of this tube terminates in the centre of an inverted "T" tube through which the air is drawn from the outside, and also through which the oil vapour and air is delivered to the mixing chamber D. From there the mixture is delivered to the burners B by means of the tubes C C.

Fig. 2 is a section of the lamp in a plane through the delivery tubes C C. Fig. 3 is a section of the same lamp in a plane through the inverted "T" tube F F'. The oil enters the lamp at the lower end of the vaporising tube G. The heat of the mantles on either side vaporises the oil in it. The vapour rushes out through a minute hole in the upper end of the tube up into the tube F'. In doing so it draws air in through the tubes F F', and the air and vapour passing up through F' strike against the top of the mixing chamber, and are thoroughly mixed. Thence it is forced from the mixing chamber by more vapour coming in, and is delivered to the burners, where it burns with a blue flame. This flame heats the mantles to incandescence and produces a light of great intensity, yet mellow and pleasing to the eyes. Lamps can be made having one, two, three, or any number of burners. The consumption of oil is very small.

To test consumption of oil a two-burner lamp was cleaned thoroughly, new mantles were put on, and it was lighted. The light was burned 162 hours, and the consumption was 8 galls. of oil, i.e., at the rate of 10.1 hours for  $\frac{1}{2}$  gall. of oil. During the entire test the lamp was not touched in any way except to light it and turn it out.

The safety of the lamp is one of its principal features. The body of oil is in the tank, and is thus so far from the lamp, and conducted to it in such small quantities, that it makes explosion impossible. This feature, combined with the portability, the cheapness and beauty of the light, makes it highly commendable for country houses. For outside lighting, the tank may be put in the bottom of the lamp-post, making each one an isolated plant.

In one of my tests, the lamp was placed in such a strong draught that one side of the mantle nearest the source of the draught was cooled and consequently not incandescent, while the rest of that mantle and the entire other mantle were as bright as usual. Upon the draught being stopped, the whole mantle again became bright. This is simply to show what little effect a draught has upon the burning of the lamp.

The mantle supports differ from ones similar to those used on the Welsbach gas lamp. In this lamp, the Washington mantle has at its top, a bail so to speak, and the wire support for it has at its upper end, a hook, upon which the mantle is hung. This makes the support really a point, enabling the mantle to swing in any direction, while in mantles having suspensions similar to the Welsbach, they crack off near the top because they are suspended upon an axis, and can only swing two ways, backward and forward.

Another important point in favour of the hook supports is that the supports, never having to be removed, to change mantles, the new mantles are the same height above the burner, on both burners, and consequently both burn with equal brilliancy. This height being once fixed, for maximum brilliancy, is never changed when necessary to replace old mantles. The Washington mantles are, and of course, have to be, much stronger than mantles for gas burners. The intense heat, baking them so hard that they become like china, in so doing prolongs their life, making them last about 1,000 hours.

In the Washington lamps, it will be noticed that there are no shadows from the side tube, the reason being that the sources of light are so large that the rays overlap, and consequently can produce no shadows. For this reason, together with the steadiness of the light, it is admirably adapted to stereopticon use.

#### DISCUSSION.

Mr. MEXX, in reply to a question from the chair, said that the lamp was stated to be 1,000 candle power. He had compared it with the standard arc lamp, to which it proved equal. He could turn the lamp down until the mantle burned red, but as the vaporisation depended on the heat from the mantle, he would not advise turning it lower than about half candle-power. It was somewhat affected by cold and outside disturbances, but when burning full a cold draught did not affect the vaporising tube and it burned steadily.

Mr. LEWIS T. WRIGHT said that anyone who had had occasion to review fuel gas must have remarked the number of recent lamps to burn alcohol or light petroleum spirit. Every month he had noticed numbers of inventions on the Continent of this form of lamp—a form which, no doubt, would be very useful in places unsupplied with gas or electric light; but he thought that the author's estimate of 1,000 candles somewhat high, and that a strict determination would show that these mantles were giving about the same amount of light as a Welsbach mantle with a gas supply, viz., about 60 to 80 candles per mantle. The author had not informed them as to what class of oil was used, but he presumed that it was gasoline of very light gravity.

Mr. MEXX said it was ordinary kerosene of about 150 flash test, such as was in general use.

Mr. WRIGHT, continuing, said that assuming 80 candles to be the light given by one of these mantles and the consumption for 16 hours to be half a gallon, that would give the same duty as oil burning in an ordinary petroleum lamp, which would appear to be rather low, so it was perhaps possible the amount of light emitted was in reality rather more than from the ordinary Welsbach gas burner.

Mr. MUNNS, in reply, said that a Welsbach lamp burning by the side of this lamp appeared as if about half-turned down, but on turning out the Washington lamp it proved to be giving a full bright light. As regarded the amount of heat generated he had made no tests, but he could say that in the centre of the flame, with the mantles removed, platinum melted, indicating a temperature of about 3,600 degrees.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Steam Plant, Leakages in.* Engineer, 84, July 23, 1897, 84.

THE importance of leaks in a steam plant is brought out with startling distinctness by the following calculation:—A square inch of area will discharge  $\frac{1}{10}$  lb. of steam per second for each pound absolute of pressure. Suppose a station to have 125 lb. gauge, 140 lb. absolute pressure, then a square inch of area would discharge 2 lb. of steam per second, or 7,200 lb. an hour, which, at the standard rate of 30 lb. per hour per horse-power, is 240 horse-power. The inquiry is made as to how many leaks it takes to aggregate a square inch. In a small station, it is thus suggested, the unsuspected leaks may assume a very large proportion of the steam produced.

*Formation of a Dangerous Boiler Incrustation by Lime washed out of Concrete.* Dingler's Polyt. Jour. 305, [4], 96.

A BAD case of boiler incrustation, due to lime dissolved out of the cement used in a newly constructed water-channel, is reported from the laboratory of Drs. Hendershagen and Philip (Stuttgart), in a communication to *Giessler's Baumaterialienkunde*. The feed-water, which was drawn from a pure, soft river supply, which had never before occasioned any trouble, was found, after passing through the conduit, to contain 0.06 grm. of calcium hydrate per litre; in consequence, a very hard incrustation formed in the boiler, causing the overheating and burning of the boiler-plates. On analysis, the incrustation was found to have the following composition:—Moisture, 0.30; combined water and trace of organic matter, 21.87;

calcium oxide, 67.20 (as hydrate, but partially combined with silica); magnesium oxide, 0.78 (as hydrate, but partially combined with silica); calcium carbonate, 7.50; calcium sulphate, 0.28; alumina, 0.40; ferric oxide, 0.16; soluble silica, 1.40 (combined with calcium and magnesium); and clay, with trace of sand, 0.11 per cent.

As lime decreases in solubility in proportion as the temperature of the water rises, such an incrustation is deposited most readily on the hottest parts of the boiler plates.—H. H. B. S.

## PATENTS.

*Drying, Distilling, Concentrating, and other like Purposes, Impts. in Vacuum Apparatus for, and in the Method of and Means for Obtaining and Maintaining Vacuum therein.* J. Longshaw, Burlington Street, Liverpool. Eng. Pat. 9084, April 30, 1896.

THE vacuum pan or evaporator A is connected through the pipe B and condenser C with the air-tight receiver F, from which the water can be drawn off through the long dependent pipe K, so as to always maintain a partial vacuum in the evaporator. Instead of, or in conjunction with, the pipe

K, a pump, &c. connected to the pipe L may be employed to draw off the water. In starting the apparatus, the main valve  $V^6$  is closed, and the branch valve  $V^2$  opened, steam being admitted through the valve  $V^1$  and blown off through the valve  $V^2$  until all the air is expelled from the evaporator. Next, the valves  $V^1$ ,  $V^2$  are closed, and the water-supply valve  $V^4$  and branch valve  $V^3$  opened until the receiver F and coil C are filled with water. Finally, the valves  $V^3$ ,  $V^4$  are closed, and the valve  $V^6$  and the discharge valve of the pipe K or L opened.

The claims, given briefly, are:—(1.) For the apparatus as a whole, and as described and figured. (2.) For dependent pipes, such as K, for the purpose given. (3.) The method of producing a vacuum in vacuum apparatus, by the aid of a water elevator or of a dependent pipe, K, or both.—R. A.

*Washing or Leaching Granular Substances and Separating the same from the Liquids used, Impts. in Apparatus for.* R. Moodie, Alkham Road, Stoke Newington, London, N. Eng. Pat. 10,784, May 19, 1896.

THE liquid and granular materials are placed in proper proportions in the tank A, in which they are mixed by the revolving stirrer B. The arms of this stirrer consist of upwardly and outwardly directed tubes or open channels, through which the mixed materials are lifted and discharged through the passage 1 into a settling tank. From this tank the liquid flows through the receiver F into the tank D. By removing the plug G from the pipe 2 to the pipe 3, the liquid can be passed back through the tank A, to wash out any solid matter remaining therein. An adjustable elbow

\* Any of these specifications may be obtained by post by remitting 6d.—the price now fixed for all specifications, postage included—to C. N. Dalton, Esq., Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

pipe is provided to drain the remaining liquid from the settling tank into the receiver F at the finish of the operation.  
—R. A.

*Filtering Apparatus, Impts. in.* J. A. Orme, Egremont, County of Chester. Eng. Pat. 11,080, May 21, 1896.

The filtering medium is placed between perforated plates in a vertical cylinder. The feed-water enters at the bottom of the cylinder and, flowing upwards through the filtering media, escapes through a pipe attached to the cylinder cover. Soluble chemicals may also be added to the material to purify the water in transit through the apparatus.  
—O. H.

*Evaporating Apparatus, Improved.* R. H. F. Finlay, Belfast. Eng. Pat. 16,552, July 27, 1896.

A CHAMBER is attached to the bottom of the vacuum-pan, so that, during evaporation, the solids deposited may be from time to time removed without stopping the process. The solid deposits are caught on a perforated plate in the chamber, while the liquor passing through may be aspirated again into the vacuum-pan. Suitable valves are fitted to enable these operations to be carried on, while a cleaning door is fitted in the chamber above the perforated plate for removal of the sediment.—O. H.

*A Still or Tank for the Distillation, Boiling, and Holding of Acids, Alkali, and other Corrosive Liquids.* D. Bray, Cinderford, Gloucester. Eng. Pat. 16,877, July 30, 1896.

THE base, sides, and cover of a still or cistern are formed of single blocks of a selected stone, such as the grey "Forest of Dean" or "Pennant" stone, squared and dressed, and having grooves made in their touching surfaces to receive pieces of solid rubber as packing, forming tight joints. The bottom and sides are clamped together, the iron bands being tightened by bolts and nuts or the like.—E. S.

*Decanting Apparatus, Impts. in.* W. L. Wise, London. From Messrs. Solvay and Co., Brussels, Belgium. Eng. Pat. 17,980, Aug. 13, 1896.

THE apparatus consists of a box or casing, funnel-shaped at the bottom, with a valved aperture, and an overflow at the top. The turbid liquid flows into a compartment formed on one side by a solid plate reaching nearly to the bottom, so that it may not overflow before being cleared, by passage upwards through a series of inclined parallel plates arranged to divide the interior of the box into many equally spaced and inclined compartments. Each of these plates is provided on its under side with a series of half partitions or vanes, approximately at right angles to the

plate, forming inverted angular troughs, which impede the upward flow of the liquid, and give time for deposition to take place on the inclined ledges which these vanes constitute. Thus, the deposit, as it forms, settles continually to the bottom, whilst the liquid, cleared as it rises, flows off at the top. It is stated that "the arrangement is such that the decanting apparatus comprises a very large number of small decanting chambers or passages, each of which acts as an approximately horizontal or slightly inclined tube of rectangular section." The apparatus is shown in two cross sections taken at right angles to one another, one of the sections having an upright, and the other an inclined form.  
—E. S.

*Condenser for Steam-heated and Similar Pans or Vessels, chiefly applicable to those used in treating Aromatic Substances; A New or Improved.* J. F. Henderson, Manchester. Eng. Pat. 7413, March 23, 1897.

THE patentee claims the combination of a hollow dome provided with a cover, in and through which a current of cold water circulates, in pans or vessels for extracting the aromatic principles of Lops, &c. The whole arrangement forms a condenser, and it is fitted with an inlet pipe near its lowest side and circumference, with the delivery end tangentially disposed to the circumference. It is also fitted with an outlet or discharge pipe in its uppermost and central part.—O. H.

## II.—FUEL, GAS, AND LIGHT.

*Illuminating Gas; Papers read at the Annual Congress of the Société Technique du Gaz en France.* J. Gas Lighting, 1897, 70, 109—110.

THE grate invented by J. Kudliez, of Prague, for the combustion of breeze, coal dust, &c., was described by M. Jouanne. It is constructed of cast-iron plates, and has conical perforations, 0.15 in. wide at top and 0.7 in. at bottom, numbering 128 per square foot. Below the plates is an underblast chamber into which a steam injector forces air at a pressure of 1 inch of water, and this blast of air and steam fans the fuel on the plates into vigorous combustion. With this grate, 1 lb. of breeze has been found to evaporate 7 to 7.4 lb. of water; whilst in another experiment 50 per cent. of the available calorific power of the fuel was utilised. The application of the grate has hitherto been chiefly for boiler furnaces, but it is adapted for any high-temperature furnace, and is to be tried shortly for heating a setting of gas retorts.

A hinged scoop for charging gas retorts was described by M. Laurain. It is 16 ins. wide and 6 ins. deep and contains the whole charge. It is built up of two quadrants of sheet steel, which are drawn apart by means of lever handles when the scoop is in the retort. The coal then drops through the longitudinal opening in the scoop on to the bottom of the retort. The scoop is used in conjunction with a stirrup support, which travels on an overhead rail in front of the bench of retorts. Three men are necessary for its manipulation, and 30 to 40 seconds are occupied in charging each retort.

A scheme for converting transverse to longitudinal benches of retorts for the better accommodation of stoking machinery in the retort house was given by M. Leclaire. A feature of the scheme is the erection of settings of 12 retorts. Six of the retorts are connected in pairs, with one ascension pipe per pair. Each setting is 12 ft. 4 ins. wide, and is capable of carbonising 11.8 tons of coal per 24 hours.—J. A. B.

*Gas Industry. Notes on the By-Products of the.*

H. Bunte. J. für Gas-beleucht. 40, 1897, 405—407.

THE relation subsisting between the staple product and the by-products of the gas industry has altered greatly in recent years. A glance at the present and probable future position of the by-products—coke, tar, ammoniacal liquor, and cyanogen—is not inopportune.

The importance of coke as a household fuel is gaining recognition, but, except in gas- and waterworks, coke and breeze are very seldom used as boiler fuels. Yet

their use in large towus would afford a simple solution of the problem of smoke-prevention. A grate constructed to burn coal requires considerable alteration before it becomes suitable for burning coke. The heat of combustion of coke is the most important factor in computing its value as a fuel; but very scanty information exists on the composition and calorific value of coke. The results given in the annexed

table refer to average samples of coke from the gasworks at Berlin, Breslau, Munich, and Hamburg. The air-dried coke has an average value of 6,959 calories per kilo., with a maximum deviation of about  $\pm 8.5$  per cent. Though this calorific value is less than that of good coal, yet uniform and smokeless combustion of coke may be attained in suitable furnaces, and a higher duty than from other fuels secured.

Tar and ammonia have suffered depression from the output of coke-ovens. Ammonium sulphate has fallen in value continuously in recent years, owing to over-production at gasworks, coke-ovens, and the Scotch shale distilleries, and it can in future only yield a very moderate return. The chief use of ammonia (about 90 per cent.) is as sulphate, for manurial purposes, and this use is now threatened by the appearance of another competitor in "nitragin," a preparation for inoculating soil, so as to aid the assimilation of atmospheric nitrogen by plants. Experiments with nitragin have not, so far, been very successful, and its competition has not yet been keenly felt (see this Journal, 1896, 767). Ammonia in other forms than the sulphate yields better returns, but the production of other ammonium salts is too specialised an industry for general adoption in gasworks. In some medium-sized works, a concentrated gas-liquor containing about 15 per cent. of ammonia, is now made in place of ammonium sulphate (which contains 25 per cent. of ammonia). Gas liquor is now largely used for the production of liquefied pure ammonia for refrigerating purposes.

Cyanogen has recently been the most valuable constituent of the spent oxide from the purifiers, but the production of cyanide has now greatly increased, and equals, if it does not exceed the demand. Hence the value of spent oxide rich in cyanogen has dropped.—J. A. B.

*Naphthalene in Modern Gas Manufacture, and the Carburetting of Illuminating Gas.* W. Young and T. Glover. J. Gas Lighting, 1897, 70, 16—19.

MODERN gasworks practice aims at securing the highest illuminating value, expressed in sperm candles, from the coal upon the smallest area. Carbonisation at high heats, and condensation wherein dense liquid hydrocarbons are removed before they take into solution gaseous hydrocarbons, have been found to achieve that aim, but at the sacrifice of high illuminating power. Moreover, this system of carbonising and condensing favours the production of naphthalene and its deposition as a solid in the gas mains. The gas so produced is free from hydrocarbons of similar vapour tension and boiling point to naphthalene, though they occur in gas made at lower temperatures and in canal gas. When they occur they are deposited as liquids whenever naphthalene is deposited, and take it into solution. But it is unscientific and wasteful to allow the products from common coal and canal to commingle in the hydraulic main, as the carburetting products of the canal are thus largely spent in absorbing the naphthalene from the common coal. The liquid condensation products of coal-gas absorb its naphthalene on prolonged contact, but at the same time absorb other illuminants and impoverish the gas. The ordinary enriching

agents have higher vapour tensions than naphthalene, and do not hinder its deposition as a solid.

Deposition of naphthalene might be avoided in three ways, *viz.*: (1.) By carbonising only a portion of the coal as at present, and another portion or some canal, at lower heats, and mingling the gases, after condensation apart. The low-temperature products would then absorb the naphthalene left in the gas made at high temperatures. Or carbonisation might be pursued at low heats only, and the rich gas produced used to enrich carburetted water-gas made from the coke and liquid products of the carbonising process. (2.) By scrubbing gas after condensation, with a hydrocarbon liquid which absorbs naphthalene, and preferably also by vaporisation, which enriches the gas. The naphthalene would be subsequently removed from the absorbent by cooling and pressing or by distillation. (3.) By carburetting gas with hydrocarbons having the same vapour tension as naphthalene and depositing along with it as liquids which dissolve it. The volume of such hydrocarbons must, however, be restricted, as they carry down also other carburetting vapours and thus impoverish the gas.

—J. A. B.

*Carburine [Petroleum Spirit] as an Enricher of Coal-Gas; On Three Years' Use of.* J. Davis. J. Gas Lighting, 1897, 70, 19–23.

CARBURINE, *sp. gr.* 0.680 [or petroleum spirit], has since the autumn of 1893 been used by means of the Maxim-Clark carburetor for raising the illuminating power of coal-gas at the Gravesend works to 16 candles. Prior to that time "North Wales Curley" canal, costing 19s. 4d. per ton delivered, had been used, and an enrichment of  $1\frac{1}{2}$  candles then cost 2.24d. per 1,000 cb. ft. of gas. Carburine cost 8½d. per gallon delivered; and the same degree of enrichment cost 2.07d. during a year in which carburine alone was used as the enricher, for nine months. One ton of the above canal appeared to be equivalent to 63 gals. of carburine, whereas Field takes one ton of "Lesmahagow" canal as equivalent to 50 gals. of carburine. Coal-gas tested at the outlet of the exhaustor was found to range from 12 to 17 candle-power within one hour. Carburine enrichment was most economically carried out when the gas in one holder was raised from 20 to 22 candle-power, and the requisite quantity of this rich gas was worked out with the unenriched gas from other holders as required. Sugg's "Illuminating Power Meter" indicated little or no loss in illuminating power of the carburine-enriched gas at points a mile distant from the works. Carburine enrichment was found to hinder deposition of naphthalene.

Experiments in which one fluid ounce of carburine was taken up by 10 cb. ft. of gas showed that the volume of gas was raised to 10.15 cb. ft., and its candle power from 14.88 to 19.86. One gallon of the carburine thus represents 24 cb. ft. of 352-candle gas.—J. A. B.

*Calcium Carbide Industry: Its Economic Importance to Germany.* A. Frank. Zeits. f. Elektrochem. 1897, 3, 427.

IN spite of the recent "acetylene panic," the calcium carbide industry merits careful attention, especially in countries which are not able to supply their own sources of light. Germany produces about 750,000,000 cb. m. of coal-gas, mostly from her own coal. In addition to this she consumes over 8,000,000 hectolitres of petroleum, for which she is dependent upon foreign countries. Not only is Germany unable to control the price of this, but within a few years she may have to submit to a sudden and enormous increase in the price if the Russian and American petroleum-producers succeed in creating the universal monopoly for which they are striving. Six litres of petroleum give about the same amount of light as 15 cb. m. of coal-gas in ordinary burners; so that an import of 8,000,000 hectolitres of petroleum corresponds in illuminating value to 2,000,000,000 cb. m. of coal-gas. This indicates a large dependence upon foreign countries, to which must be added imports of other lamp-oils, tallow, &c. Altogether it is computed that Germany pays 100,000,000 mks. per annum to foreign countries for sources of light.

In countries which possess large sources of water-supply, such as Switzerland and Norway, large factories for the

production of calcium carbide are already being erected. Germany is not so well supplied with water-power; but in her peat-moors she has an almost inexhaustible source of power. The author draws special attention to the great peat-moor in East Friesland, of which scarcely any use has been made, although the Prussian Government has provided facilities for opening it up by constructing a canal. Attempts to export the turf have not proved remunerative; for, on account of its relatively low heating power, it cannot compete with the neighbouring Westphalian coal. But it offers excellent conditions for the fabrication of carbide on the spot, especially as the other materials required can be obtained within a reasonable distance. 30 tons of peat will supply the electrical energy required for the production of 1 ton of calcium carbide.—D. E. J.

## PATENTS.

*Coking Ovens, Impts. in.* B. Grau, Kratzwick, b. Stettin, Germany. Eng. Pat. 17,198, Aug. 4, 1896.

To enable the linings or inner walls of the heating flues to be made of less thickness than usual and thereby obtain a more intense heating effect, they are formed of bricks of C- or L-section.—R. S.

*Coke from Anthracite and Similar Coal, An Improved Process for Making.* L. J. Davies, Cardiff. Eng. Pat. 12,096, May 15, 1897.

ANTHRACITE or similar coal is powdered, then mixed with either about 20 per cent. of pitch, or 25 per cent. of tar, or with a mixture of the two. The whole is then coked as usual.—R. S.

*Siemens' Regenerative Furnaces, Impts. in and connected with.* F. Szoboda, Aksohi, Hungary. Eng. Pat. 10,763, May 19, 1896.

The encircling or outer plates of the furnace are made sloping instead of vertical, to effect economy in the material used in their construction, to assist in cooling, and for greater durability. The air- and gas-canals or pipe conduits are divided into two or more compartments between the reversing device and the heat accumulators, and the rate of inflow or outflow in these compartments is regulated by means of dampers, which are operated automatically by the reversing apparatus.—R. S.

*Gas Generators, Impts. in and relating to.* T. Hennessy, Kansas City, U.S.A. Eng. Pat. 28,718, Dec. 15, 1896.

THE plant consists of a superheater and two generators working alternately or concurrently. The fuel is fed to the latter through hoppers situated on one side above the generators, and air is blown in to drive the products of combustion into the superheater, where they ascend through the system of checker bricks, with which the latter is filled, and are ignited at the top for the purpose of heating a secondary current of air passing between the walls of a superimposed hood, and thence, *via* a second annular heating chamber at the top of the superheater, into a pipe debouching into the last-named at a lower level, and there igniting the carbon monoxide from the generators. In this way the temperature of the superheater is raised to about 2,190° F., whereupon the mouth of the superheater is

closed, and steam is passed through the fuel in the generator, the water-gas thereby produced being delivered to the upper part of the superheater. Here it is carburetted by means of gas-naphtha or other suitable oil vaporized by passing through a heating coil in the head of the superheater, the operation being facilitated by diverting a jet of the water-gas into the oil pipe, the high temperature of the gas (about 2,000° F.) rendering it a more efficient agent for this purpose than the steam usually employed. The carburetted gas is thoroughly fixed during its passage downwards through the superheater, and is conducted through a water-seal and discharge pipe at the bottom of the apparatus, to the condenser.

The apparatus may be worked either with an upward or downward draught through the generator, and can be modified for working with either an air blast or an exhauster.

The generator grates consist of piping, through which is passed a current of water, which may then be used for heating adjoining compartments.—C. S.

*Water-Gas, Improved Method and Apparatus for Removing Gaseous Iron Compounds from.* H. Strache, Vienna. Eng. Pat. 16,984, July 31, 1896.

In this apparatus the gas, entering at the bottom, passes upwards through a lead-lined scrubber containing pumice moistened with concentrated sulphuric acid, which removes the objectionable iron compounds and dries the gas. The acid is sprayed by being dropped through a pin-valve on to a curved leaden disc situated above the pumice, and since its capacity for freeing the gas from iron is very great and it leaves the apparatus in a condition of 50 per cent. dilution, only 16 grms. are required per cubic metre of gas, or 0.5 grm. per second, when the apparatus is working at the rate of 100 cubic metres of gas per hour.

—C. S.

*Carbon Dioxide and Hydrogen, Improved Means for Producing.* B. T. L. Thomson, London. Eng. Pat. 17,778, Aug. 11, 1896.

THE inventor proposes to modify the treatment of these gases, generated in accordance with his patent (Eng. Pat. 6835 of 1896), in that they may be separated by dissolving the carbon dioxide in water under pressure, the residual hydrogen being freed from carbon monoxide by passing it through cuprous chloride, the dioxide being subsequently liberated by reducing the pressure. It is then stored for use. An alternative method is to absorb the carbon dioxide by means of an alkali carbonate in solution. An excessive current of steam in the carbon retorts is desirable, and the gases should be passed through another retort containing some inert material, such as firebrick, to facilitate the oxidation of the carbon monoxide.—C. S.

*Luminous Flame, Process for making Spirit burn with a.* F. W. H. Hempel, Berlin. Eng. Pat. 6463, March 11, 1897.

The spirit burning with a non-luminous flame is mixed with from one-sixth to one-half its weight of a volatile hydrocarbon; e.g., turpentine oil previously enriched with carbon by rapid distillation along with naphthalene or other solid hydrocarbon. An addition of glycerin, in the proportion of 5 to 10 per cent. of the turpentine oil employed, will "soften" the liquid and enable the wick of the lamp to be lighted with ease, even after having been out of use for some time.

In distilling the turpentine oil, the naphthalene ( $\frac{1}{3}$ rd to  $\frac{1}{2}$ th part) is first dissolved by heat and the whole then heated rapidly (to ensure the naphthalene vapour being carried over with that of the turpentine) until merely a slight brown residue is left.—C. S.

[*Incandescent Lighting.*] *Bunsen Burners, Impts. in.* A. Lecomte and L. Loeser, Paris. Eng. Pat. 8385, April 1, 1897.

The improvements relate to Bunsen burners working with gas at very low pressures (8 to 10 mm. of water),

capable of being used under the ordinary incandescence burner galleries. The claim is for "the combination of an ejector, A, having a single central hole of conical form, forming an angle of about 30°, with two converging cones, B and C, arranged one above the other and having different angles, the lower cone, B, having an angle about equal to the angle at which the gas expands, and the upper cone, C, having an angle considerably greater—preferably about seven to nine times greater—than the angle of the lower cone." The burner shown in the illustration is slipped up into the burner-top in the usual way.—H. B.

*Gas, Improved Method and Composition for making.* A. A. Stephenson, Sydney, N.S.W. Eng. Pat. 10,371, April 26, 1897.

A COMPOSITION is patented for producing gas, by passing air through it. It consists of camphorated chalk, resin, salt, and shale oil. This material is further treated with gasoline, ether, petroleum, and carbon bisulphide. The method is also patented.—C. S.

*Incandescent Gas Lighting, An Impt. in Burners for.* L. Denayrouze, Neuilly, France. Eng. Pat. 21,371, Sept. 26, 1896.

THIS invention can be understood from the illustration, which shows a mantle, M, suspended over the improved burner.

The claim is: "In combination with a Bunsen burner for incandescence, a fixed or adjustable shell, K, enclosing and approximately fitting the ovoid form assumed by the gas and air issuing from the burner tube, and terminating with a pervious diaphragm, T, on a level with what would be the apex, C, of the blue cone observed where there is a flame without an enclosing shell."—H. B.

*Burning Liquid Fuel, Improved Method and Apparatus for.* F. Altmann, Berlin, Germany. Eng. Pat. 29,258, Dec. 28, 1896.

THIS relates to the production from liquid fuel of a hot smokeless blue flame, suitable for incandescent lighting, cooking, heating, soldering, and other purposes, including the ignition of the combustible charges in gas and like engines. The process consists in simultaneously evaporating water and vaporising the fuel, and then mixing and burning the vapours produced. Two forms of lamp are illustrated, in each of which there are two distinct compartments, one for fuel, the other for water, and a small lamp for vaporising the fuel and water. The mixed vapours pass to an ordinary burner for ignition.—R. S.

**Burner [Lamps], Improved Circular, for use in connection with Liquid Hydrocarbons having different Carbon Contents.** F. W. H. Hempel, Berlin, Germany. Eng. Pat. 6462, March 11, 1897.

To admit of the regulation of the supply of air to the interior and exterior of circular burners of the kind indicated, according to the quality of liquid hydrocarbon used, the air is admitted to the slot leading to the interior of the burner through a perforated diaphragm, the space enclosed thereby being entirely or almost entirely cut off from any connection with the outside of the flame by a crown piece. Above the crown piece are two concentric perforated short cylinders, one fixed, the other rotatable, for admitting air to the outside of the flame, and the supply of air thereto is regulated by causing the holes in the two cylinders to coincide more or less.—R. S.

**Liquid Fuel Burners, Impts. in.** P. M. Justice, Chancery Lane, London. From The Société Anonyme du Générateur du Temple, Paris, France. Eng. Pat. 11,571, May 10, 1897.

Has reference more particularly to burners for firing steam boilers. A single burner may be used, or a number of them may be supported parallel to one another around a hollow cylindrical drum. Both arrangements are illustrated. Each burner is carried by two supports. Through the rear one is admitted the liquid fuel, which passes to the forward end through an adjustable hollow tube or needle; and through the forward one is admitted the compressed air or steam, which is delivered around the outlet of the liquid fuel, this annular outlet being made larger or smaller by means of the adjustable needle. By removing a plug in the rear, the needle may be easily removed for cleaning, &c. When several burners are used, the hollow supporting drum is provided with means for heating the liquid fuel before it enters the nozzles.—R. S.

**Acetylene, Impts. in Apparatus for the Production of.** G. E. Redfern, London. From "La Compagnie Continentale d'Eclairage par le Gaz Acétylène et ses Applications Industrielles," Paris. Eng. Pat. 15,064, July 7, 1896.

A GENERATOR containing several compartments for carbide is supplied with water from a tank above a bell gas-holder into which the gas generated passes. The rise and fall of the bell operates a valve on the water-supply pipe. The gas passing from the holder is purified by spongy material impregnated with suitable salts.—J. A. B.

**Acetylene Gas, Impts. in and connected with Apparatus for Generating and Storing.** L. T. F. Gibbon, South Kensington. Eng. Pat. 17,038, July 31, 1896.

The fall of a gas-holder bell opens a cock which allows a small vessel of water to be discharged into a carbide container. The rise of the gas-holder due to the gas thus generated allows the vessel to be refilled from an overhead water-tank. Or carbide agglomerated by means of paraffin, &c., may be discharged intermittently into water. Or, either the carbide or the reacting water may be mixed with suitable inert material to moderate the action.—J. A. B.

**Acetylene, Impts. in Process and Apparatus for Generating and Liquefying.** A. C. Fraser, New York. Eng. Pat. 17,678, Aug. 10, 1896. (Under Internat. Convention.)

ACETYLENE is generated in a close vessel of great strength, and cooled. It is then led to a cooler, terminating in a water separator; thence it passes to refrigerators and to a compressing pump, from which it goes through a cooling coil, and emerges in the liquid state. The gas is generated at a comparatively low pressure, and the final liquefaction is preferably effected at a very low temperature, and consequently low final pressure. Suitable apparatus for generating, cooling, refrigerating, and compressing the gas is described.—J. A. B.

**Acetylene Gas, Impts. in Apparatus for Generating, Storing, and Delivering.** E. Chesnay and L. Pillion,

both of Dijon, France. Eng. Pat. 18,992, Aug. 27, 1896. (Under Internat. Convention.)

THE counter-weight of a gas-holder bell, is a water reservoir communicating with the lower half of a generator, the upper part of which contains carbide on a suitable support.

—J. A. B.

**Acetylene Gas, Impts. in or appertaining to the Production of, and Apparatus therefor.** W. P. Thompson, Liverpool. From D. H. Chivert, of Neuilly-sur-Seine, France. Eng. Pat. 19,059, Aug. 28, 1896.

THE bell of a gas-holder floats in an annular space surrounding but independent of a water reservoir. A hopper containing granulated carbide is placed within or above the bell, and the fall of the latter opens the feed-valve of the hopper and allows carbide to fall into the water in the reservoir, and generate acetylene.—J. A. B.

**Acetylene Gas, Improved Apparatus for the Production and Storage of.** E. A. Morton-Brown and F. Maundrell, both of Woodstock, Canada. Eng. Pat. 22,628, Oct. 12, 1896.

THE carbide is contained in a perforated cylinder automatically revolved in the generator. The tank of the gas-holder is partially occupied by a condenser, through which the gas passes, for the abstraction of moisture. The rise and fall of the bell of the holder automatically control the admission of water to the generator. The gas-holder has a closed cover.—J. A. B.

**Acetylene Gas, Impts. in Apparatus for Producing.** G. Voigt, Berlin. Eng. Pat. 19,126, Aug. 29, 1896.

THE rise and fall of the gasometer bell actuates, through suitable gearing, the supply of water from a reservoir to carbide receptacles. The water-feed pipes and gas-exit pipes are attached to a plate which forms the cover of the carbide receptacles. A worm in the reservoir is employed to cool the evolved gas.—J. A. B.

**Acetylene Gas, Improved Apparatus for the Production and Storage of.** J. G. Kerr and C. Fry, Niagara Falls, Canada. Eng. Pat. 2989, April 8, 1897.

THE apparatus consists of a generating chamber containing two or more receptacles for carbide, to which a flow of water, regulated by a trap siphon which rises and falls with the gas-holder bell, has access. The receptacles are on a revolvable base-plate, so that they may be brought beneath the water supply and a recharging lock in turn. An electric alarm indicates exhaustion of the gas-holder.

—J. A. B.

**Acetylene Gas, Impts. in or connected with Apparatus for the Production and Consumption of.** W. P. Thompson, Liverpool. From "The Deutsche Acetylen-Gesellschaft mit beschränkter Haftung," Berlin. Eng. Pat. 10,249, April 24, 1897.

THE generator consists of a water-chamber above a carbide receptacle. Water passes to the carbide through a knee-pipe furnished with a diaphragm valve, which is closed automatically by the pressure of gas in the carbide receptacle. Condensation of moisture in the gas-exit pipe is prevented by carrying the latter entirely outside the water chamber. A safety device for removing the residual gas from lamps, &c., when they are extinguished, is provided.—J. A. B.

**Acetylene Gas, A New or Improved Automatic Apparatus for the Production of.** R. Quatannens-Moens, Dismude, and E. Carreër-Dilger, Bruges, Belgium. Eng. Pat. 12,556, May 20, 1897.

THIS apparatus consists of a generator surrounded by a cooling reservoir. Water is supplied to the carbide in a suspended basket in the generator through a pipe entering the base of the latter from an elevated tank in which a fixed level is maintained. The gas passes from the generator, through a washer and purifier, to the burners, or to a reserve gas holder.—J. A. B.

*Acetylene Gas Generators, Impts. in.* F. A. Mitchell, Wilmington, Delaware, U.S.A. Eng. Pat. 13,496, June 1, 1897.

A GASOMETER moves in a water reservoir from which an adjacent generator is supplied. The water reservoir contains also a fixed overflow gas-holder, to which the stream of gas is diverted when the pressure in the gasometer becomes excessive. The supply of water to the generator is governed by a valve actuated by the gasometer. A pump for removing gas from the generator prior to recharging, is attached.—J. A. B.

*Electric Incandescent Lamps, Impts. in Filaments [Borates] of.* F. E. W. Bowen, Ealing. Eng. Pat. 16,435, July 24, 1896.

A FILAMENT is claimed, in the body of which is incorporated metallic borates of a refractory character. Cellulose, or cellulose filament, is soaked in solutions of the nitrate or other soluble salt of the metal and of boric acid, and caused to react to produce the borate (Eng. Pat. 3213 of 1896; referred to, this Journal, 1897, 149).—J. C. R.

*Incandescence Vapour Lamps, Impts. in.* P. D. de la Grée, Paris. Eng. Pat. 17,131, Aug. 1, 1896. (Under Internat. Convention.)

THE improved lamp comprises—(1) Means for giving pressure to the petroleum, either by injecting air into the reservoir or by means of a descending piston actuated by a spring within the reservoir; (2) an expansion device, on, say, the Carcel or Toecheboeuf system for regulating the pressure of the petroleum which arrives at the burner; (3) the burner proper; and (4) the lighting parts, consisting of a small flange or sleeve in which alcohol can be employed for the preliminary heating, the alcohol being contained in a reservoir located in the lamp body, whence it is raised by a small pump. The burner consists of a bent tube rising upwards from the expansion device and provided internally with a metal spiral, where the petroleum is vaporised; a "butterfly sieve" to filter the petroleum vapours; a casing surrounding the vaporiser and sieve, and terminated at its upper end by the usual gauze, where the vapours burn; and a heat-conducting rod, placed in the flame and supplying the heat to the vaporiser. The various combinations are claimed.—H. B.

*Incandescence Burners for Vapour Lamps, Impts. in.* P. D. de la Grée, Paris. Eng. Pat. 18,391, Aug. 19, 1896. (Under Internat. Convention.)

IN the improved burner, the socket from which the usual mantle support rises, consists of a metal rod, which at its lower extremity is in contact with the wick. The claim is for "an improved incandescent burner for ordinary petroleum lamps, in which burner the heat disengaged beneath the mantle is conveyed to the upper extremity of the wick of the lamp by the conductive action of a metal rod of appropriate shape placed in the flame; while the air required for producing a carburetted gas mixture arrives at the sides of the burner and is mixed with the vapours produced at the extremity of the wick, so that this mixture may then be ignited above a grate terminating the burner."—H. B.

*Incandescent Mantles or Caps for Gas and other Burners, A New or Improved Method of Manufacturing.* R. Moll and A. Palmer, Germany. Eng. Pat. 26,784, Nov. 25, 1896.

IT is proposed to manufacture mantles by impregnation in the usual way, as suggested in the following claim:—"A new or improved method of manufacturing incandescent mantles, caps, or like appliances, marked by the use of salts having sodium for their base and silicates or borates, and also of a smaller quantity than hitherto of salts based on thorium, cerium being entirely or partly dispensed with, substantially as set forth"—H. B.

*[Incandescence Petroleum Lamp.] Vapour Burners for Heating Purposes and for the Production of Light with a Mantle, and Means of Lighting them; Impts. in and*

*connected with.* J. T. Armstrong, London. Eng. Pat. 11,433, May 7, 1897.

AN electrical current passed through a resistance suitably arranged round the gasifying portion of the petroleum supply-pipe, generates heat sufficient for the initial supply of vapour. An electrical switch, actuated by a rotatable part of the lamp casing, sends a current through other [platinum] resistances which ignite the vapour when required. The vapour mixes with air, drawn through inlet holes, and the mixture divides into two streams, the one passing to the Bunsen burner and mantle of the usual types at the upper extremity of the lamp, while the other burns in a hollow neck surrounding the first air-mixing chamber, supplying to the vaporiser sufficient heat by conduction, to maintain the supply of petroleum vapour. The claims are for the burner, for the means of electrically generating the initial charge of vapour and igniting the same, and for the various combinations of parts. The fourth claim is for the gasifier enclosed by the conducting part "so that the efficiency of such conductor will be decreased as it gets hotter, owing to its expansion, whereby the air space between it and the retort (gasifier) will be increased, and conversely."—H. B.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Petroleum Tanks, Safety of.* Engineer, 84, July 23, 1897, 84.

THE importation of petroleum into Trieste in tank steamers has given rise to an Austrian governmental inquiry as to the vapour of petroleum hanging about the tanks, and the dangers arising from the explosive mixtures to which it gives rise. The result is that a method has been adopted by which the air from various parts of the tank is extracted and subjected to a three-fold test with a eudiometer to see whether there is any diminution of volume on explosion, with a Davy lamp to see whether the flame is altered by the suspected air, and with an open flame to see if it is inflammable, and if so, what kind of flame is produced; and it is only when these three tests are satisfactory that a light can be allowed near the tank. Otherwise, ventilation must be rigorously carried out.

*[Tar Still Explosion.] Boiler Explosions Act, Official Inquiries under the.* Board of Trade J., Aug. 1897, 132.

A FORMAL investigation was held at Manchester on the 27th instant into the circumstances attending the explosion of a boiler, or still, at some chemical works at Bradford, Manchester, on the 19th June last.

On the 14th June, anthracene oil was run into the still, and after light oil and creosote had been distilled therefrom, the result of the distillation changed to anthracene on the night of the 15th June. The distillation of this product ceased at 3 a.m. on the 16th June.

Anthracene solidifies at a temperature of 70° F., and on the early morning of the 16th June the weather was unusually cold. On the morning of the 17th June some tar was run into the still, and the fire was lit about 8 a.m. At 10.30 a.m. there was a terrific explosion; the upper part of the still was blown over a wall, the released tar was set on fire, the stillman and boiler attendant being killed.

The Court found that the still was properly constructed for the purpose for which it was intended, but that it should have been fitted with an efficient safety-valve placed on the swan neck.

There was no evidence to show what means were taken by the stillman to ascertain whether the pipes were clear before lighting the fire on the morning of the 17th June.

The Court were of opinion that the explosion was due to the pipe leading from the still to the worm becoming sealed up from the solidification of anthracene.

It was proved at the inquiry that stills of this description have been in work for at least 35 years, and that it has not been the practice to fit them with efficient safety-valves, as in their ordinary working conditions they are not liable to steam pressure.

In these circumstances the Court exonerated the owner and his manager from blame, and they made no order as to costs.

*Wood Spirit, Presence of Ethylic Alcohol in Raw. G. Arachequesne. Bull. Assoc. Chim.* **14**, [11], 1108-1111.

THE presence of traces of alcohol having been demonstrated on several occasions in wood spirit by the official method of Kiehe and Hardy, both in that from distilling wood and from the dry distillation of vinasses, it has been suggested that its presence might be due to the use of earboys which had previously contained ethylic alcohol and had not been rinsed. But as sealed samples taken from the vat before filling into earboys, also showed coloration indicating traces of ethylic alcohol, this explanation had to be abandoned. Various samples of wood spirit were tested without result until, after distilling the base of a pile of wood, very damp and attacked by fungus, traces of alcohol were again found. The same result followed on two other occasions when brushwood was used with some of the leaves still attached, and again from vinasses distilled by the Vincent process. In the latter case the explanation is easy, although no fermentation alcohol could have been left in the vinasses, as they are not introduced into the retorts for dry distillation until they have been brought to a pasty condition by evaporation on the hearth of a furnace similar to the Porion furnace; but the molasses, and consequently the vinasses derived from it, must have contained lactate of lime from the fermentation in the char filters universally employed in sugar works. From this to the synthesis of alcohol by the dry distillation of calcium lactate is but one step:— $C_3H_5O_3 + CaO = CaCO_3 + C_2H_5O$ .

This explanation could scarcely apply in the case of the distillation of wood, even supposing the fungus had formed lactic acid at the expense of the cellulose, since the reaction requires an excess of lime.

In the production of acetone by distilling crude grey pyrolignite of lime, which contains calcium formate and other salts of fatty acids, aldehyde is formed, from which alcohol may be produced by hydrogenation. No trace of the reaction is found on distilling pure calcium acetate in the laboratory.

The proportion of ethylic alcohol, when it exists, is so small as to offer little interest of itself industrially, except as regards suspicion of fraudulent evasion of the excise regulations.—L. J. de W.

\* *Wood, Modern Distillation of, for the Production of Acetic Acid, Wood Spirit, and Acetone in a Pure Form. M. Klar. Chem. Ind.* 1897, **20**, [7], 152-158, and [8], 176-180.

ALTHOUGH the primitive method of making charcoal by charring wood in heaps (Meiler) is no longer carried on in Germany—the carbonisation being now almost exclusively conducted in retorts for the purpose of obtaining at the same time acetic acid, wood spirit, and acetone—the old process is still very generally worked in other countries where forest lands abound. Recently, however, efforts have been made everywhere to turn forest wealth to better account, and in this respect, America has led the way by starting a large number of works for the carbonisation of wood with special reference to the production of acetate of lime and wood spirit. Russia is also making rapid progress in this direction. According to private information communicated to the author by Titschenko, the carbonisation of wood is carried on almost exclusively, and in a most primitive manner, by Russian peasants in the governments of Welsk, Vologda, and Archangel, in the crown forest and the forests of the apanage resorts. Latterly, however, great changes have taken place, partly owing to the rapid development of the Russian textile industry, but mainly on account of the increase in the import duty on acetate of lime and acetic acid in 1891.

The conditions which influence the yield of acetic acid in distilling wood in retorts, are the species and the

nature (moisture) of the wood, the size of the charge, the mode of firing, the temperature and duration of the carbonisation, the pressure in the retort, and the construction of the latter. Since woods with foliage, grown on a dry soil and felled in mid-winter give the best yield, well-seasoned timber is mostly employed, such as oak, barked birch, and especially red beech. (Air-dried wood contains about 20 per cent. of water.) The wood of coniferous trees is less adapted for the production of acetic acid; however, inasmuch as it yields oil of turpentine, resin, and tar in large quantities, special appliances for their rapid removal from the retorts and their subsequent condensation have been devised. Experience has proved that the best yield of acetic acid is obtained by heating the wood gradually to a maximum temperature of 350°. It is further essential to withdraw the acid vapours, as they are liberated, rapidly from the retort, for which purpose exhausters are used. By allowing the gas to remain in contact with the heated iron walls of the retort and failing to adopt measures for preventing the formation of pressure therein, decomposition takes place and loss ensues.

The apparatus most generally employed may be divided into three groups: (1.) Carbonising apparatus for leaved woods, (a) with horizontal retorts, (b) with vertical retorts. (2.) Carbonising apparatus for woods of coniferous trees. (3.) Carbonising apparatus for wood waste, sawdust, and the like. Almost all the drawings accompanying this paper are reproductions of typical forms of apparatus constructed by the firm of E. Leinhaus, of Freiberg, Saxony. The diagrams exhibited in Figs. 1 and 2 represent the side and

Fig. 1.

Fig. 2.

front elevations respectively of a carbonising plant worked with horizontal retorts, this form being most generally adopted in Germany. The retort consists of a wrought-iron cylindrical vessel, to the front end of which an iron charging door, working on hinges, is attached, the volatile products being carried off by a pipe at the back. The size most usually chosen renders it possible to work off two charges in 24 hours, the retort being capable of taking two billets lengthways. The charging is effected by manual labour—mechanical contrivances, as used in gas-making, not having as yet been applied. Each furnace contains two retorts, the flues and arches being arranged so that the flame does not play directly on to the retort. The retorts are heated by the gas liberated from the wood, which is aided by a coal fire. Wood tar is used when its market price is lower than its fuel value. Other

\* For earlier literature of Wood Distillation, see Muspratt's *Dict.* 1869, Art. "Acetic Acid"; Spon's *Dict.*, Art. "Acetic Acid"; E. T. Chapman, *Chem. News*, Feb. 24, 1871, 91-93, also 105; Watson Smith, *J. Chem. Soc.* 1871, 1104.

sources of heat are superheated steam and hot gases, such as carbonic oxide, carbonic anhydride, nitrogen, generator- and water-gas. Although when using superheated steam it is possible to control the temperature more accurately and attain greater uniformity, its adoption in practice has not been attended with profitable results, owing to the fact that it enhances the cost of the entire apparatus, as the vessels must be strengthened in every part and the system of condensation augmented. The dilution of the products is another objection. Zwillingger (this Journal, 1891, 129) proposes to effect the carbonisation by forcing air charged with steam and heated to 320 to 400 into the retort, having previously freed the air as much as possible from oxygen by washing it at 90°. Leinhaas has patented a charring oven, which is heated by gas, the waste heat, instead of passing away to the chimney stack, being introduced into the actual coking apartment, wherein a temperature of 200° to 260° is maintained by the admission of an easily regulated supply of air. The gaseous products are exhausted by means of high-pressure exhausters, the liquid products being condensed, whilst the gases, after passing through a washer, escape to the oven, where they are burnt. The advantages are: (1.) The oven being constructed entirely of brickwork, the repairs are small. (2.) The production of solid, hard charcoal in large pieces. (3.) The formation of acetic acid containing from 10 to 12 per cent. of pure acid. (4.) Saving of a chimney stack and of fuel. (5.) Saving in labour, it being possible to carbonise logs 1½ metres in length and 300 mm. in thickness.

To economise heat, the ovens are usually arranged in groups and joined together, the furnace gases being utilised, before they escape to the chimney, for heating evaporating pans, drying chambers, and the like. By working the retorts in batteries and introducing the charges at different stages, so that the distillation is completed, say, in the first retort as the last is receiving its load, the process is facilitated and the labour utilised more judiciously. The charcoal is transferred by various mechanical contrivances to wrought-iron coolers, advantage being frequently taken of an iron disc to which a chain is attached. This is drawn to the front after the carbonisation is completed, the charcoal falling into the subjacent cooler. The pipe destined for carrying off the gaseous products is led to the condenser, each containing two coils for cooling the gases from two retorts. The worm consists of copper pipes, which are placed at a certain inclination. The elbow pieces connecting the pipes are on the outside of the condensing tank, and, being readily disconnected, the pipes can be easily and efficiently cleaned. On distilling woods yielding much tar, a tar separator is inserted between the retort and the condenser. To prevent any return of the gas towards the retorts a water seal is employed. The crude acetic acid is collected in wooden vats or underground tanks lined with planks, in which it is allowed to settle as long as possible to separate all tarry matter—an acid which has been well settled, offering numerous advantages in its subsequent treatment.

For the carbonisation of wood in vertical retorts the condensing and separating plant is similar to that used in the case of horizontal retorts. The retorts are wrought-iron cylinders, set in pairs in brickwork, as illustrated in Fig. 3, special provision being made to prevent injury to the retort by direct contact with the flame. A crane travelling on rails above the brickwork lifts the retort out of its bed, after the charge has been worked off, and conveys it to the charcoal store; whilst another retort, previously charged, is immediately lowered into the vacant space with a second crane. The heat radiating from the brickwork is thus economised and the necessity for providing charcoal coolers obviated. The product is said to be greater and of superior quality. Such an installation is, however, very costly, as twice the number of retorts is required, and the frequent removal of the retorts gives rise to greater wear and tear.

For distilling the wood of coniferous trees, an arrangement for separating the oil of turpentine and resin is required in addition to the usual condensing apparatus. For this purpose Hessel's thermo boilers are used; they are vertical retorts set in brickwork, the flues being arranged so

that the shell of the retort only is exposed to the fire, the bottom being protected. The retorts are stationary, and carry the necessary mountings for removing the gaseous

Fig. 3.

products and introducing steam, superheated or otherwise. Immediately above the bottom of the retort, provision is made for discharging the charcoal after the carbonisation is completed. The more volatile products, before entering the condenser, are passed through a separator or a series of separators, in which the tarry constituents are collected, whilst the fused resin and the heavier products are carried away through a pipe near the bottom of the retort. The pipe which conducts the gaseous products to the condenser is connected with two coolers, one of which condenses the oil of turpentine and the other the ordinary products, such as acetic acid, light tars, &c.

For the production of oil of turpentine, the retort is heated at the commencement of the carbonisation by a gentle fire, the operation being aided by the simultaneous introduction of steam, which is eventually superheated. Before condensing the gaseous products they are passed through milk of lime. When the distillate ceases to show particles of oil, the steam is shut off and the carbonisation completed by external firing. The oil of turpentine is in the first place redistilled with ordinary or superheated steam; it is then rectified by distilling it under a partial vacuum, to free it from creosote, and finally fractionated in column stills. By subjecting the resinous constituents to fractional distillation, a further quantity of oil of turpentine is obtained. The lighter portions are successively washed in emulsion apparatus with soda, water, acid; again with water, and finally redistilled with steam.

A number of patents have been secured by Bergmann for the carbonisation of wood waste, such as sawdust, spent dye wood, and tanner's bark (this Journal, 1895, 857). It is proposed to mould the materials into perforated briquettes, by subjecting them to great pressure, after which they are heated in horizontal retorts. The charcoal is said to be sufficiently solid to be transported without falling to pieces.

To draw the products of distillation out of the retort immediately they are formed, and to carry them at once to the condenser, Schmidt has patented a method, which consists in blowing through an injector, heated air at a suitable point into the discharge pipe of the distilling retort.

Crude acetic acid obtained from wood, the carbonisation of which has been properly conducted, contains, besides tarry substances and the homologues of acetic acid, about 10 per cent. of acetic acid, 1 per cent. of methyl alcohol, and 0.1 per cent. of acetone. On subjecting it to distillation, the tarry constituents are in a great part removed and wood spirit distils over. The separation of the latter is effected either by a simple process of distillation or by first combining the acid with a base and expelling the spirit therefrom by the aid of heat. For the distillation the apparatus shown in Fig. 4 is mostly employed. It is capable of

Fig. 4.

yielding from 3,500 to 7,000 litres of product in 24 hours. The crude acid is pumped into the copper still A and heated with steam. The volatile products are carried into the receiver B, containing slaked lime, wherein the acetic acid is absorbed, whilst the wood spirit passes through the condenser C, which is provided with a spirit seal, and is collected in a suitable vessel. Owing to the accumulation of tarry matter in A, which necessitates frequent cleaning, attempts have been made to remove the greater part before introducing the acid into the still. For this purpose an apparatus has been patented by the firm E. Leinhaas, of Freiberg, which is illustrated in the accompanying diagram (Fig. 5). It consists of three vats fitted with copper and

Fig. 5.

phosphor-bronze mountings. The first contains a funnel pipe, through which a suitable clarifying substance is introduced. Having charged the vat with crude acid, a gentle heat is applied by means of a steam coil, when the clarifying agent, as it dissolves, causes the tarry matter to separate out and rise to the surface of the acid. The filtration is effected in the second vat and the cooling in the third, from which the greater part of clarifying agent is recovered, the balance remaining behind in the first vat.

When the slaked lime in B (Fig. 4) has been sufficiently saturated with acetic acid, the acetate liquor is passed through a filter press to separate excess of lime and tarry impurities. According to Black, the lime sludge remaining in the press is mixed with sawdust, tanner's bark, or similar waste material, moulded into briquettes, and subjected to destructive distillation, the volatile products, such as acetic

acid, acetone, and tar, being condensed, whilst the gas and charcoal are utilised as fuel. The acetate of lime liquor is evaporated in copper pans, the usual construction being that shown in Fig. 6. The pan is heated by a steam jacket.

Fig. 6.

and contains a set of stirrers to prevent the acetate from burning to the bottom. The tarry matter separated during this operation and after acidification with hydrochloric acid, is removed through a sliding door, through which the progress of the operation is simultaneously watched. The acetate is then dried in suitable rooms heated with waste furnace or retort gases. During this operation the last traces of tarry substances are decomposed, a grey product remaining, which contains from 80 to 82 per cent. of calcium acetate.

The purification of crude spirit is effected by subjecting it to filtration through wood charcoal in a tower, the construction of which is shown in Fig. 7. The object is to remove the greater part of the ketones, tarry bodies, and

Fig. 7.

hydrocarbons, after which the rectification is proceeded with. This is performed in column stills in the presence of lime. Figs. 8, 9, and 10 represent the forms most generally adopted. The stills have a capacity ranging between 1,000 and 3,000 litres. The apparatus consists of a wrought-iron or copper still, a copper condenser contained in a wrought-iron water tank, a copper separator fitted with return pipe, a refrigerator provided with seal and the necessary steam and water fittings. To maintain a uniform pressure in the column, a manometer is used, as shown in Figs. 8 and 10, in addition to which a thermometer is frequently employed to control the flow of spirit. The water used for cooling is introduced into the refrigerator at the bottom,

and having reached the requisite temperature, passes into the water tank containing the condenser, whence it either runs away or is pumped to the upper part of the column. The temperature of the water as it leaves the apparatus should be ascertained from time to time, to determine whether it is that which experience has shown to give the best result. The first distillate, known as first runnings, is always more or less coloured. The temperature is then carefully noted, together with the density of the distillate, and the receiver is changed as soon as the middle fraction, constituting

Fig. 8.

Fig. 9.

spirit of the highest concentration, begins to distil over. After this, higher boiling products come over, their presence being first noticeable by the turbidity of the distillate produced when water is added to it. Subsequently the distillate itself is rendered turbid, and eventually it comes over in two layers—oil and water, the quantity of the latter increasing until, at the end of the distillation, water only distils over, impregnated with empyreumatic substances. The fraction from which water separates oily products, is washed with water, and the washings are added to the turbid

distillate. The mixture is then redistilled in the next still with a fresh charge of crude spirit. The oily fractions are mixed together and redistilled separately, when a further quantity of middle fraction is obtained.

Fig. 10.

The treatment of wood tar for the production of creosote and guaiacol is not practised very largely by wood-ecking establishments, most works being contented with its utilisation as waggon grease, or for the preservation of timber, for which purpose it is dehydrated. For the recovery of its products, it is treated with lime and subsequently dehydrated in stills having a steam jacket at the bottom. The fractionation is effected in cast-iron tar stills of 1,000 litres capacity, heated by a direct fire. The first product is wood spirit; then acetic acid comes over. The distillate up to 150°—known as light oils—has a specific gravity of about 0.980, whilst the heavy oils distilling up to 250° have a specific gravity of about 1.01. Above this temperature the quantity of paraffin and gaseous products increases, and towards the end, anthracene comes over. The residue in the still is wood-tar pitch, and forms a considerable proportion of the original material. For the production of creosote, the light and heavy oils are mixed together and neutralised exactly with soda to remove fatty acids. They are then fractionated, the portion distilling between 150° and 250° being collected separately. This is treated with a concentrated solution of potash or soda, allowed to settle, run off, boiled to expel hydrocarbons, and acidified with sulphuric acid. This operation is repeated until the product is completely soluble in alkali. The final traces of phenol are removed by washing the oil with weak soda or ammonia. It is then redistilled, oxidised with chromic acid mixture, and fractionated in glass, the portion boiling between 205° and 220° being collected separately. This has a specific gravity of not less than 1.07, and represents the creosote of the German Pharmacopœia.

Guaiacol, which is the active principle of wood creosote from beech tar, of which the latter contains about 60 per cent., is now prepared in a pure form by subjecting wood creosote to distillation and treating the fraction boiling between 200° and 205° repeatedly with moderately strong ammonia to separate acids and phenols. The product is then redistilled. The low-boiling portions are dissolved in ether and treated with a strong alcoholic solution of potash. The potassium salt is washed with ether, recrystallised from alcohol, decomposed with dilute sulphuric acid, and fractionated, the distillate boiling at 200°—202° forming pure guaiacol. On cooling the latter by a freezing

mixture to  $-10^{\circ}$ , chemically pure guaiacol separates out. It boils at  $205^{\circ}$  and has a specific gravity of 1.113. According to von Heyden, Nachfolger, the separation of guaiacol and cresol from phenols is effected by preparing the corresponding barium salts and separating the more readily soluble phenol salt by fractional crystallisation. Rumpf for the same purpose recommends their conversion into magnesium compounds, the phenol salt being readily soluble.—D. B.

#### IV.—COLOURING MATTERS AND DYES.

1,1'-Dihydroxynaphthalene Sulphonic Acid. L. Paul. Zeits. f. angew. Chem. 1896, 619—620.

By fusing naphthol disulphonic acid *S* [ $\alpha$ -naphthol- $\beta$ -disulphonic acid (Schöllkopf)] with caustic soda, it is converted into 1,1'-4-dihydroxynaphthalene sulphonic acid, which gives with diazo and tetrazo compounds, dyestuffs of very bright blue shades, capable of forming chrome lakes. Thus the dyestuffs from diazotised sulphamile or aniline sulphonic acids yield dyestuffs similar in shade to magenta, but possessing much greater fastness to milling and light than the sulphonic acids of phenylrosinduline, known as azoearmine. For the preparation of the 1,1'-4-dihydroxynaphthalene sulphonic acid, 6 kilos. of caustic soda and 2 litres of water are heated to  $120^{\circ}$  C. until dissolved, in a cast-iron vessel provided with an agitator. 4 kilos. of caustic soda in small pieces are then added, and the whole raised to  $180^{\circ}$  C. in about  $3\frac{1}{2}$  hours, until completely dissolved. In the course of  $2\frac{1}{2}$  hours, 4 kilos. of sodium  $\alpha$ -naphthol- $\delta$ -disulphonate (92 per cent.) are then added, the temperature rising to  $210^{\circ}$ — $215^{\circ}$  C., which is maintained for about  $2\frac{1}{2}$  hours. A sample of the melt is then dissolved in water, filtered, acidified with acetic acid, and treated with diazobenzene solution until all the dihydroxy acid is precipitated as dyestuff. When the filtrate, on the addition of sodium acetate and diazobenzene, gives no further precipitate of dyestuff and does not on the addition of ammonia yield an orange colour, due to the presence of undecomposed disulphonic acid, the reaction is complete, and the melt is run out. After cooling, it is dissolved in 31 kilos. of hydrochloric acid ( $20^{\circ}$  B.), boiled up with wet steam, and filtered from the precipitated hydroxy acid. The press cakes, weighing 7 kilos., are then dissolved in water, and, after titration with diazobenzene, the solution is used directly for the preparation of dyestuffs. From 3.68 kilos. of 100 per cent.  $\alpha$ -naphthol- $\delta$ -disulphonic acid, 2.96 kilos. of 1,1'-4-dihydroxynaphthalene sulphonic acid were obtained, corresponding to 72.7 per cent. of the theoretical yield.

—T. A. L.

$\alpha$ -Amido- $\beta$ -Naphthol Ethers. L. Paul. Zeits. f. angew. Chem. 1896, 620—622.

By replacing  $\alpha$ -naphthylamine by the ethers of its  $\beta$ -hydroxy derivative in the manufacture of dyestuffs, much brighter and bluer shades are produced. The following details are given with regard to the manufacture of these raw materials:—In a cast-iron vessel provided with an agitator, 4 kilos. of alcohol ( $95^{\circ}$  Tr.) are quickly mixed with an equal weight of sulphuric acid ( $66^{\circ}$  B.); then 4 kilos. of  $\beta$ -naphthol are added, and the whole is heated for 6—8 hours to  $95^{\circ}$  C. The melt is then transferred to another vessel, allowed to cool, and the upper layer of solid  $\beta$ -naphthol ethyl ether melted with 25 litres of water and 1.5 kilos. of soda lye ( $40^{\circ}$  B.). After cooling, the ether is washed with 25 litres of hot water, fused, and dried, the yield being 4—4.2 kilos. In order to nitrate it, 3 kilos. of the ether are mixed with the same weight of water and heated in a brine bath to  $90^{\circ}$  C.; then nitric acid ( $40^{\circ}$  B.) is run in until a reaction commences, which requires about 1.5 kilos. The temperature is maintained at about  $95^{\circ}$  C. by running in about 2 kilos. more of nitric acid during 5—6 hours. The crude nitro-product, after washing with hot water, weighs  $3\frac{1}{2}$  kilos.,

and when crystallised from 15 kilos. of alcohol, weighs 2—3 kilos., and solidifies at  $94^{\circ}$  C. The recrystallised product is then dissolved in 8 kilos. of alcohol and rapidly stirred whilst cooling, in order to obtain it in a fine state of division, and after adding 6 kilos. of hydrochloric acid ( $20^{\circ}$  B.), zinc dust (4.2—4.5 kilos.) is slowly added, the temperature being maintained at  $80$ — $90^{\circ}$  C. 7 kilos. of hydrochloric acid are then added, and later another quantity of 5 kilos., in order to precipitate the  $\alpha$ -amido- $\beta$ -naphthol ethyl ether hydrochloride. For purification, 4.5 kilos. of the crude hydrochloride are dissolved in 45 litres of water, slightly acidified, filtered, and precipitated with 20 kilos. of hydrochloric acid ( $20^{\circ}$  B.). The hydrochloride is then stirred to a paste with water, and gives 8.1 kilos. of a 24.3 per cent. paste = 1.97 kilos. of 100 per cent. salt, or 45 per cent. of the theoretical yield calculated on the naphthol. The base is obtained by neutralisation with 1.25 litres of soda-lye ( $40^{\circ}$  B.) and extraction with benzene, when it forms a slightly dark, crystalline mass. It can be acetylated by dissolving 280 grms. in 2.5 times its weight of benzene and adding 170 grms. of acetic anhydride. After crystallising from water, the substance forms thin colourless needles, melting at  $114^{\circ}$  C. The yield is 110 grms. The preparation of an amido- $\beta$ -naphthol methyl ether is carried out in the same way, 5 kilos. of nitric acid being required, and 3 kilos. of crude nitro product being formed, melting at  $112^{\circ}$ — $115^{\circ}$  C. On recrystallisation, this gave 1.8 kilos., melting at  $125$ — $125^{\circ}$  C. It is, however, doubtful whether the amido-naphthol ethers will have a general technical employment, owing to their cost.—T. A. L.

*Nitrobenzene, The Fusion Point, Boiling Point, and Specific Gravity of.* R. J. Friswell. Proc. Chem. Soc. 1897, [182], 147—148.

Great discrepancies are found in the books as to the above constants.

Schultz gives in his first edition, 1882,  $1.2002$  at  $0^{\circ}$  and  $1.1866$  at  $14.4^{\circ}$ ; in his second edition,  $1.208$  at  $15^{\circ}$ . Fusion point  $+3^{\circ}$ .

Beilstein gives the same, and quotes Mitscherlich for the fusion point and Kopp for the specific gravity.

Gmelin gives  $1.209$  and  $+3^{\circ}$ , and quotes Mitscherlich. As to boiling points, Gmelin, quoting Mitscherlich, gives  $213^{\circ}$ ; Schultz, 1882, gives  $210^{\circ}$ ; in 1886,  $206$ — $207^{\circ}$ ; Beilstein, quoting Stille,  $205$  at  $730$  mm.

It would thus appear that several of these numbers have been quoted unverified for over 60 years.

No statement of specific gravity of solid nitrobenzene has been published, excepting that in *Watts' Dictionary*, given to A. G. Green in a private communication by R. J. Friswell. Determinations of the various points have been made. Calculated for comparison with water at  $4^{\circ}$  the sp. grs. are:—

	<i>t</i>	<i>d</i>
Solid.....	$1.5$	$1.3440$
Liquid.....	$3.8$	$1.2220$
".....	$13.0$	$1.2160$
".....	$28.0$	$1.1931$

Boiling point corrected  $209^{\circ}$ . Melting and solidifying point  $+3^{\circ}$ .

Nitrobenzene is remarkable as having a distinctly coloured vapour very closely resembling that of chlorine. The colour is easily visible in a thickness of about 2 ins., and is strongly marked when 6—8 ins. are examined. The author is not aware of any other organic vapour of so simple a constitution which is visibly coloured.

No bands of absorption are shown in the visible spectrum when light is transmitted through this vapour. The violet and blue are absorbed as with the fluid, but less strongly.

*Nitrobenzene, The Action of Light on a Solution of, in Concentrated Sulphuric Acid.* R. J. Friswell. Proc. Chem. Soc. 1897, [182], 148—149.

NITROBENZENE is, as has long been known, readily soluble in concentrated sulphuric acid of  $1.84$  sp. gr. and upwards, but a comparatively small amount of dilution precipitates it, and at about  $1.7^{\circ}$ , the solubility is very slight.

When a solution in pure concentrated acid is exposed to light it slowly darkens. When exposed to direct sunlight, the darkening goes on with great rapidity, and in a few minutes the solution becomes quite black and opaque; then the action ceases. The light from burning magnesium produces the same effect.

The solution has been kept unchanged in the dark for upwards of four years. If the exposure to light takes place in a stoppered bottle, a slight odour of sulphurous acid is perceptible after some time in the air above the solution.

If the nitrobenzene thus used be recovered and redistilled, and then redissolved in sulphuric acid, it behaves in exactly the same way.

Attempts were made to increase the change by spreading the solution on glass beads and between sheets of glass, but the depth of colour of the product soon brought all power of perceiving further change to an end.

Several hundred grammes of the black solution were prepared and attempts made to isolate the products of the change, but though a brownish calcium salt was obtained and an ammonium salt in solution, the latter decomposed on evaporation with a caramel-like odour; what was left was treated with phosphoric chloride, but no satisfactorily pure product could be obtained. The matter needs further investigation.

The rate of blackening of the solution is undoubtedly a measure of the actinic power of the light.

The author thought it quite possible that the change in the solution of nitrobenzene in sulphuric acid when exposed to light was of the same kind as that induced by electrolysis. He had never observed any coloration on sulphonating nitrobenzene when the materials were pure and light was excluded.

*Chloronaphthalenedisulphonic Acids into Dichloronaphthalenesulphonic Acids.* Conversion of: H. E. Armstrong and W. P. Wyne. Proc. Chem. Soc. 1897 [182], 152—154.

In the course of their studies of naphthalene derivatives, the authors have had occasion to make great use of phosphorus pentachloride as an agent for displacing the  $\text{SO}_2\text{H}$  radicle by chlorine. It was therefore necessary to establish in every possible way the validity of this method of determining constitution in the naphthalene series, as it is obvious that the occurrence of isomeric change in any one case would materially weaken the force of all arguments based on its application.

With regard to the nature of the interaction, it is to be noted that, in a previous communication (Proc. Chem. Soc. 1895, 11, 83), it has been shown that the main function of the pentachloride is to promote the elimination of  $\text{SO}_2$  from the  $\text{SO}_2\text{Cl}$  radicle.

In the case of the chloronaphthalenesulphonic chlorides, the amount of dichloronaphthalene obtained by means of phosphorus pentachloride is relatively considerable, and the residue left after its removal from the crude product by distillation with steam yields nothing but the original chloronaphthalenesulphonic acid on hydrolysis.

The chloronaphthalenedisulphonic chlorides, however, behave somewhat differently, affording but a comparatively poor yield—rarely exceeding 30 per cent. of the theoretical amount—of trichloronaphthalene.

The authors have felt it to be incumbent on them to thoroughly examine the residues left after separating the trichloronaphthalenes, which they have had occasion to produce on a large scale (Proc. Chem. Soc. 1895, 11, 86). Although, in view of the uniformity of the end-products, it was improbable that any change in orientation had taken place at the somewhat high temperatures at which the interactions were effected, it was obviously important to ascertain in every possible way whether such was the fact. The results to be recorded are of interest, as they serve in every case to justify the conclusion previously arrived at, that the treatment of sulphonic chlorides with phosphorus pentachloride may be thoroughly trusted as a means of determining constitution in the naphthalene series. Two

cases may be quoted as typical of the behaviour of chloronaphthalenedisulphonic chlorides in general.

When 2-chloronaphthalene-4':2'-disulphonic chloride (this Journal, 1890, 800—801) is heated with the theoretical quantity of phosphorus pentachloride at  $175^\circ$  during two hours, it yields both 2:4':2'-trichloronaphthalene and 2:4'-dichloronaphthalene-2'-sulphonic chloride in about equal proportions, about 50 per cent. of the material remaining unchanged. 2:4'-Dichloronaphthalene-2'-sulphonic acid affords a sparingly soluble barium salt, crystallising with  $3\frac{1}{2}$  molecular proportions of water in microscopic needles; a sparingly soluble potassium salt, containing  $1\frac{1}{2}$  molecular proportions, in thin scales; a chloride crystallising from benzene in small prisms melting at  $156^\circ$ ; an amide crystallising from dilute alcohol in slender needles melting at  $196^\circ$ ; and when the chloride is heated at  $180^\circ$ — $185^\circ$ , with phosphorus pentachloride it is converted into 2:4':2'-trichloronaphthalene. On hydrolysing the chloride in sealed tubes with concentrated hydrochloric acid at  $290^\circ$ , or the potassium salt with a mixture of sulphuric and phosphoric acids and superheated steam, 2:4'-dichloronaphthalene is obtained. The course of change may therefore be thus represented:—

When 2-chloronaphthalene-1':3'-disulphonic chloride (this Journal, 1890, 283) is similarly heated with phosphorus pentachloride, it yields 2:3':1'-trichloronaphthalene-3'-sulphonic and 2:3'-dichloronaphthalene-1'-sulphonic chlorides (Proc. Chem. Soc. 1890, 84), about 50 per cent. of the material remaining unchanged. 2:1'-Dichloronaphthalene-3'-sulphonic acid, the isomeride present in the larger proportion, yields an anhydrous potassium salt, a chloride crystallising from benzene and light petroleum, and an amide crystallising from dilute alcohol. When the chloride is heated at  $180^\circ$ — $185^\circ$  with phosphorus pentachloride, 2:1':3'-trichloronaphthalene is formed. On hydrolysing the chloride in sealed tubes with concentrated hydrochloric acid at  $290^\circ$ , or the potassium salt mixed with sulphuric and phosphoric acids, in superheated steam, 2:1'-dichloronaphthalene is obtained. The course of change may therefore be thus represented—

The other  $\alpha$ - $\beta$ -disulphonic chlorides behave similarly, the tendency being, however, as in the first of the above instances, to form only one of the two possible isomeric dichloronaphthalenesulphonic chlorides, no doubt because the  $\text{SO}_2$  of the  $\text{SO}_2\text{Cl}$  radicle, like the  $\text{SO}_2\text{H}$  radicle, is more easily displaced from  $\alpha$ - than from  $\beta$ -positions. It is not certain that these products are intermediate in the strict sense of the term, as the effect of prolonging the heating with phosphorus pentachloride at the minimum temperature at which the reaction takes place serves only to increase the yield both of the dichloro- and trichloro-derivatives. As the dichloronaphthalenesulphonic chlorides produced in these interactions decompose at temperatures a few degrees higher— $10^\circ$  to  $15^\circ$  in most cases—than those at which the

-corresponding chloronaphthalenedisulphonic chlorides from which they are obtained undergo change, it is not difficult to understand why they escape attack by phosphorus pentachloride under the conditions observed.

**1:1'-into 1:4'-Dichloronaphthalene by Hydrogen Chloride.** *Conversion of. The Products of Hydrolysis of 1:1'-Dichloronaphthalene-3-Sulphonic Acid.* H. E. Armstrong and W. P. Wynne. *Proc. Chem. Soc.* 1897, [182], 151-186.

When 1:1'-dichloronaphthalene is heated with concentrated hydrochloric acid at 290°, it is wholly converted, save for a trace of carbonisation, into the isomeric 1:4'-dichloronaphthalene. This remarkable isomeric change does not seem to occur at temperatures below 200°, but is noticeable at 250°, and complete at 290°; it does not occur when 1:1'-dichloronaphthalene is heated either alone or with water, or with concentrated phosphoric acid at 300°, but does happen when it is heated with sulphuric acid of a strength to cause considerable carbonisation. None of the isomeric dichloronaphthalenes show any tendency to change under these conditions.

The experiments which led to these results were made in consequence of the perplexing behaviour of 1:1'-dichloronaphthalene-3-sulphonic acid on hydrolysis. The isomeric  $\alpha$ -sulphonic acid (*Proc. Chem. Soc.* 1890, 6, 81), requires only a temperature of 230° to effect its hydrolysis, and gives only 1:1'-dichloronaphthalene, whatever be the hydrolytic agent used; the  $\beta$ -sulphonic acid, on the contrary, is not hydrolysed below 285°, and, according to the agent used, gives one or other of no less than three dichloronaphthalenes.

1:1'-Dichloronaphthalene-3-sulphonic acid is obtained in addition to about an equal proportion of 1:1':3-trichloronaphthalene, when 1-chloronaphthalene-1':3-disulphonic chloride (this *Journal*, 1890, 284) is heated with phosphorus pentachloride at 160° (compare preceding abstract). It forms a sparingly soluble, anhydrous potassium salt, a chloride crystallising from benzene, an amide crystallising from dilute alcohol, and 1:1':3-trichloronaphthalene when its chloride is heated either with phosphorus pentachloride at 170°, or alone at 200°-230°. On hydrolysing the potassium salt with dilute acids, such as 1 per cent. sulphuric acid or 50 per cent. phosphoric acid, at 290°, about 5-10 per cent. of the theoretical quantity of 1:1'-dichloronaphthalene is obtained, the residue being unchanged salt—a result by which the constitution of the acid is determined beyond doubt. When heated with 5 per cent. sulphuric acid or 60 per cent. phosphoric acid, carbonisation largely occurs, and with these and stronger acids a small amount of 1:4'-dichloronaphthalene is the only substance obtained, a better yield—some 20 per cent. of the theoretical—being got when the chloride is heated with concentrated hydrochloric acid at 290°. The production of 1:4'- instead of the expected 1:1'-dichloronaphthalene under these conditions is to be referred to the action of hydrogen chloride, either present or formed during the carbonisation of the salt.

On effecting hydrolysis by heating the potassium salt, mixed with sulphuric and phosphoric acids, in superheated steam instead of in sealed tubes, an unexpected result was obtained, pure 1:2'-dichloronaphthalene, to the extent of 40 per cent. of the theoretical amount, being the product, the remainder of the salt being carbonised. The explanation of this change has yet to be given. It is certain that the 1:2'-compound is not an intermediate step in the conversion of 1:1' into 1:4'-dichloronaphthalene during hydrolysis in sealed tubes, both because it is unaffected by prolonged heating with concentrated hydrochloric acid, and because 1:2'-dichloronaphthalene-3-sulphonic acid cannot be detected in the material which has escaped hydrolysis, and, moreover, behaves normally on hydrolysis (compare preceding abstract). It is possible that, under the conditions specified, further sulphonation may precede hydrolysis, and that in consequence of the transference of chlorine to the para-position being thereby prevented, 1:2'-dichloronaphthalene is formed, thus:—

Further experiments are being made to test this view.

Of the trichloronaphthalenes, the 1:2:8-modification is the only one which undergoes change when heated with concentrated hydrochloric acid. Its sulphonic and disulphonic acids behave similarly, but the course of the action has not yet been worked out, owing to want of material.

*Diphenylene Disulphide, An Isomer of.* P. Genyresse. *Bull. Soc. Chim.* 1897, 17, 599-609.

On heating benzene with sulphur in the presence of aluminium chloride, a mixture of diphenylene disulphide (*Bull. Soc. Chim.* 15, 1035) and diphenylene isodisulphide is produced; the former is removed by extraction with glacial acetic acid, excess of sulphur by carbon bisulphide, and the diphenylene isodisulphide then recrystallised from boiling benzene, in which it is slightly soluble. Diphenylene isodisulphide,  $(C_6H_4S)_2$ , melting at 295°, is obtained in the form of fine needles by sublimation; it is slightly soluble in benzene and chloroform, insoluble in glacial acetic acid, carbon bisulphide, &c. Sulphuric acid gives with the isodisulphide an emerald green coloration, whilst the disulphide produces a violet.

*Isodisulphide of Trioxypheylene.*  $C_6S_2H_4O_3$ .—This colouring matter is obtained by the action of 10 parts of fuming sulphuric acid on diphenylene isodisulphide at 120°-125° in a sealed tube. The green contents of the tube dissolve in water to a reddish solution. After nearly neutralising with barium carbonate and evaporating on the water-bath, the substance is deposited; it is then dissolved in alcohol, the solution evaporated, and these processes repeated to free it from sulphuric acid. The compound is hygroscopic, very soluble in water and alcohol, the solutions being red; in the solid state it is brown; sulphuric acid colours it green. It has not been obtained crystalline, and is insoluble in benzene, chloroform, petroleum ether, &c.

It dyes unmordanted silk a greyish copper colour and unmordanted wool a wine red; the shades are fast to soap and light, strong in an acid bath, but feeble in an alkaline bath. It does not dye unmordanted cotton. The action on successive patterns shows that the substance is not a mixture of colouring matters. The addition of a solution of common salt to the aqueous solution precipitates a compound with the colouring matter. The addition of caustic soda (1 mol.) turns the solution black; it is now alkaline, and slowly deposits a precipitate. Carbonates give no effervescence. By the action of excess of baryta the compound  $C_6S_2H_4O_3Ba$  is obtained; this is a white substance, very slightly soluble in water. The addition of baryta until the aqueous solution changes colour, produces the crystalline substance  $(C_6S_2H_4O_3)_2Ba$ . By the action of acetic anhydride the compound  $C_6S_2O_3H(CO.CH_3)_3$  was formed; this and other reactions point to the substance being a trihydric phenol. The colouring matter gives diazo colours with amines. The reaction by which diphenylene isodisulphide is produced appears to be deep-seated. The molecular weight of the compound was found by Raoult's method to be 181, agreeing with the formulae given.—A. C. W.

*Dyestuffs [Congo], and Raw Materials therefor; Manufacture of.* L. Paul. *Zeits. f. angew. Chem.* 1896, 536-564.

The substantive cotton dyestuffs Congo Fast Blue R and B, introduced by the Berlin Actiengesellschaft, possess valuable properties as regards fastness to light and milling,

although they do not give such bright shades as Benzazurin and Congo Blue 2 B. They are obtained by combining equimolecular proportions of tetrazoditolyl or dianisidine and  $\alpha$ -naphthylamine, rediazotising, and combining with two molecular proportions of  $\alpha$ -naphthol- $\delta$  disulphonic acid (Schöllkopf). It appears to be necessary, however, to employ an excess of  $\alpha$ -naphthylamine (up to 25 per cent.), and in consequence, after the second diazotisation, in addition to the tetrazo intermediate product, there are also present unaltered tetrazoditolyl and  $\alpha$ -diazonaphthalene, which do not yield such valuable dyestuffs. With regard to the manufacture of Congo Fast Blue R, 33 kilos. of tolidine are dissolved in 50 kilos. of hydrochloric acid (20 B.) and so much water that the solution measures about 585 litres. After determining and adding the amount of hydrochloric acid necessary for the diazotisation, to the cold decanted tolidine solution, and diluting with ice and water to about 450 litres, the tolidine hydrochloride is diazotised with 28 kilos. of a 25 per cent. nitrite solution, diluted with an equal volume of water. On the previous day, 7.5–8 kilos. of  $\alpha$ -naphthylamine are dissolved in 400 litres of water and 11.7 kilos. of hydrochloric acid (12° B.), and made up to 800 litres. The tetrazo solution is run into this and allowed to stand two hours, when ice, 6 kilos. of hydrochloric acid, and 14 kilos. of a 25 per cent. nitrite solution are added. The diazotisation is complete when a test, after adding potassium nitrite solution, shows a slight excess of nitrite in the filtrate. The whole is then combined with 25 kilos. of 100 per cent.  $\alpha$ -naphthol- $\delta$ -disulphonic acid, as a 2.5–3.5 per cent. solution, together with 30 kilos. of soda lye (40° B.). After heating to 30°–40° C. the dyestuff is precipitated with 100–120 kilos. of salt, filtered under a low pressure, and dried, giving, after dilution, 95–100 kilos. of dyestuff, containing 66 per cent. of pure colour. A product having similar properties is obtained by substituting 1.3.1' naphthol disulphonic acid (e- or Andresen's acid) for the 1.4.1'-acid.

*Congo Fast Blue B* is obtained by dissolving 248 kilos. of dianisidine sulphate paste, corresponding to 49 kilos. of base to a 3.3 per cent. solution, allowing it to settle, and taking such a proportion of it that the solution contains 12.3 kilos. of base, adding 40 kilos. of hydrochloric acid (12° B.) and ice, so that the total volume is 1,180 litres. This is then diazotised with 28 kilos. of a 25 per cent. nitrite solution diluted with an equal volume of water. The combination with  $\alpha$ -naphthylamine, rediazotisation, and combination with 1.4.1'- or 1.3.1'-naphthol disulphonic acid is then effected as in the first example. The yield is about 100–110 kilos., and gives much greener shades than Congo Fast Blue R.

*Congo Blue 2 B* is the product obtained by combining tetrazo-anisol with R salt and 1.4-naphthol sulphonic acid. One-third of the above 3.3 per cent. dianisidine sulphate is mixed with 34.5 kilos. of hydrochloric acid (20 B.), water, and ice, so that the total volume amounts to 1,400 litres. The diazotisation with 10.5 kilos. of a 25 per cent. nitrite solution, diluted with an equal volume of water, is carried out at 5–10° C. the whole then amounting to 1,710 litres. This is then allowed to run into 263 litres of a 10 per cent. R salt solution, after which 38 kilos. of sodium nitrite, as a 10 per cent. solution is added, the whole stirred for one hour, and then mixed with a solution containing 18.5 kilos. of 1.4-naphthol sulphonic acid obtained by decomposing diazotised naphthionic acid by boiling with water. The mixture, after agitating for 12 hours, is boiled and the dyestuff precipitated with 50 kilos. of salt. The yield is 90 kilos., which is diluted with 15 per cent. of sodium sulphate.

The dyestuff components, the  $\delta$ - and  $\epsilon$ -naphthol disulphonic acids, are derivatives of 4.1'- and 3.1'-naphthalene disulphonic acid, and are obtained by sulphonating naphthalene, nitrating, reducing, and separating the isomeric naphthylamine disulphonic acids by crystallisation. On boiling the diazo compounds of these with water, they yield the corresponding naphthol disulphonic acids. The sulphonation of the naphthalene is carried out by melting 100 kilos. of it in a cast-iron pot provided with an agitator and running in 280 kilos. of fuming sulphuric acid during 4–5 hours. After cooling to 30° C., which takes 10–12 hours,

100 kilos. of nitric acid (40° B.) are added in the course of 18 hours. The melt is then run into milk of lime and the calcium salt of the nitro disulphonic acid converted into the sodium salt. The reduction is carried out by means of iron and sulphuric acid, and after evaporation of the sodium salt to 28° B. the solution is allowed to stand for 8 days, when the sodium salt of  $\alpha$ -naphthylamine- $\delta$ -disulphonic acid crystallises out. The filtrate treated with salt and hydrochloric acid gives crude  $\alpha$ -naphthylamine- $\epsilon$ -disulphonic acid. The yield of each acid is about 20 per cent. The mother-liquor contains a  $\beta$ -naphthylamine disulphonic acid which shows a blue fluorescence not possessed by the other acids. On diazotisation, and boiling with dilute sulphuric acid, the  $\delta$ - and  $\epsilon$ -acids are converted into the corresponding naphthol acids, the 2–3 per cent. solutions of the sodium salts obtained, being employed directly for the preparation of dyestuffs. A better yield of the  $\epsilon$ -acid is obtained by starting from  $\beta$ -naphthalene sulphonic acid. 200 kilos. of this melt, corresponding to 100 kilos. of naphthalene, are heated with 400 kilos. of sulphuric acid (66° B.) and worked up in the same way as above. The yield of a naphthylamine- $\epsilon$ -disulphonic acid is 27–30 per cent. of the theoretical. By the use of fuming sulphuric acid (23 per cent.  $\text{SO}_3$ ) and separation of the  $\alpha$ -amidonaphthalene- $\epsilon$ -disulphonic acid as acid zinc salt, a yield of about 22 per cent. of  $\alpha$ -naphthol- $\epsilon$ -disulphonic acid was obtained. Both the  $\delta$ - and  $\epsilon$ -naphthylamine sulphonic acids when fused with caustic soda yield amidonaphthol sulphonic acids, the sulphonic acid in the 1' position being replaced by hydroxyl. Chicago blue is obtained by combining tetrazo anisol with 1.1'.4'-amidonaphthol sulphonic acid ( $\delta$ -amidonaphthol sulphonic acid), which is formed from  $\alpha$ -amidonaphthalene- $\delta$ -disulphonic acid by heating 4 kilos. of the recrystallised sodium salt with 2 litres of water and 12 kilos. of caustic soda to 190° C. in an oil-bath for 12 hours. One litre of water is then added, the melt is heated for a further six hours, run out, dissolved in a mixture of hydrochloric acid and 30 litres of water, but left slightly alkaline; it is then filtered, and afterwards precipitated with 15 kilos. of hydrochloric acid (20° B.). With regard to the formation of  $\epsilon$ -amidonaphthol sulphonic acid, the best proportions appear to be the following:—450 grms. of sodium  $\alpha$ -amidonaphthalene- $\epsilon$ -disulphonate, 450 grms. of caustic soda, and 450 c.c. of water were heated for 7–8 hours in an autoclave at a temperature of 180°–190° C. and a pressure of 12 atmospheres, when 150 grms. of  $\epsilon$ -amidonaphthol sulphonic acid were obtained. Meldola's base diazotised and combined with this acid, does not give a black of technical importance.

## PATENTS.

*Pyrocatechin-sulphonic Acid and Intermediate Products, Impts. in the Manufacture of.* G. B. Ellis, London. From "La Société Chimique des Usines du Rhoue anciennement G. P. Monnet et Cartier." Lyons, France. Eng. Pat. 14,931, July 6, 1896.

STARTING with the parasulphonic acid of phenol, the patentee converts this into a chloro or bromo derivative, which, on fusing with potash, yields the sulphonic acid of pyrocatechol. When this latter product is heated with dilute sulphuric acid in an autoclave it yields pure pyrocatechol. Details of the invention are as follows:—Phenol- $p$ -sulphonic acid is obtained by heating together on the water-bath for several days, equimolecular proportions of phenol and sulphuric acid (66° B.). The melt, after cooling, is dissolved in one-third of its weight of water,

5—10 per cent. of sulphuric acid is then added, and a current of chlorine or bromine is passed into the solution in the proportion of two atoms of chlorine or bromine for each molecule of phenol sulphonic acid; for instance, 94 kilos. of phenol require 71 kilos. of chlorine or 160 kilos. of bromine. During the operation, the temperature rises from 20° to 60° C. The melt, after pouring into water, is lined and converted into the sodium salt, which is then mixed with half its weight or an equal weight of caustic soda in an aqueous solution, and heated either in an open vessel or under pressure for 8—10 hours to 250° C. or above. The product is dissolved in water, neutralised with 30 per cent. sulphuric acid in slight excess, the solution evaporated to a syrupy consistency, filtered from the sodium sulphate which crystallises out, and the concentrated aqueous solution of the sodium salt of pyrocatechol sulphonic acid obtained is finally heated in an autoclave with dilute sulphuric acid, yielding pure pyrocatechol.—T. A. L.

**New Dyes [Yellows] relating to the Oxy-phenanthro-naphthazine Series and of New Intermediate Products, The Manufacture and Production of.** J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 15,953, July 18, 1896.

AN extension of Eng. Pat. 18,374 of 1893 (this Journal, 1894, 942), which described the preparation of new basic dyes from phenanthrophenazine. The present specification relates to the production of similar dyestuffs derived from phenanthronaphthazine, which contain a hydroxyl group and give very fast yellow shades on wool and silk. These products are obtained by condensing phenanthraquinone (a) with peri-hydroxydiamidonaphthalenes and subsequent sulphonation; (b) with peri-hydroxydiamidonaphthalene sulphonic acids; and (c) with certain 1,2-diamidonaphthalene sulphonic acids (the 1,2,4- and 1,2,4'-diamidonaphthalene sulphonic acids are not suitable). In this last-mentioned condensation, products are obtained in which, by subsequent fusing with alkalis, a hydroxyl is substituted for a sulphonic acid group. The final products, if insoluble, may be sulphonated. The following is one of the examples given:—The azo dyestuff, prepared in an acid solution from diazosulphanilic acid and 2,1',3'-amidonaphthol sulphonic acid, is dissolved in about 20 times its weight of hot water and decolorised by adding hydrochloric acid and stannous chloride. On cooling, 1,2,1',3'-diamidonaphthol sulphonic acid crystallises out, and is washed with dilute hydrochloric acid. To effect the condensation, 402 kilos. of a 5 per cent. paste of phenanthraquinone are mixed with 260 kilos. of a 10 per cent. paste of 1,2,1',3'-diamidonaphthol sulphonic acid. About 350 litres of water are added, and the mixture is heated to 90—95° C. until the phenanthraquinone has disappeared and a sample dissolves with a yellow colour in water. The condensation product is then salted out and filter-pressed. Like the sodium salt, it is very sparingly soluble in water, and dissolves in concentrated sulphuric acid with a greenish-blue colour. By employing in place of the above acid an equivalent quantity of 1,2,1',3,3'- or of 1,2,1',4',2'-diamidonaphthol disulphonic acid, more soluble dyestuffs are obtained, which also give purer yellow shades. The sulphonic acids are obtained as above by reduction of their azo compounds with stannous chloride and hydrochloric acid. All these dyestuffs are characterised by their fastness to alkalis.—T. A. L.

**Azo Colours [Cotton Blues and Blacks], Impts. in the Production of.** T. R. Shillito, London. From J. R. Geigy and Co., Basle, Switzerland. Eng. Pat. 16,582, July 27, 1896.

THE new bases employed in the production of the azo dyestuffs referred to are *p*-diamidoditolyamine and *p*-diamidophenyltolylamine. They are obtained by the reduction of the corresponding indamines. Thus the former is obtained by reducing with hydrochloric acid and zinc dust that indamine which is produced by oxidising *p*-tolylene diamine with *o*-toluidine, whilst the latter is formed from that indamine which is the product of the oxidation of *p*-phenylene

diamine with *o*-toluidine or of *p*-tolylene diamine with aniline. The diamines may be employed in the usual manner for the production of symmetrical or unsymmetrical diazo or trisazo dyestuffs, an example of which follows:—30 kilos. of *p*-diamidoditolyamine hydrochloride in 500 litres of water are diazotised at 0° C. with 40 kilos. of hydrochloric acid (21° B.) and 14 kilos. of sodium nitrite, and mixed with a solution of 40 kilos. of sodium carbonate, to which a solution of 26 kilos. of sodium 2,1',3'-amidonaphthol sulphonic acid is then added. The intermediate compound forms a dark brown precipitate, and is mixed with a solution of 12 kilos. of *m*-tolylene diamine. After standing some hours, the dyestuff is filtered off and dried. It dyes unmordanted cotton black shades. By the use of components which, after combination, are capable of further diazotisation, trisazo dyestuffs may be obtained, which also yield dark shades.—T. A. L.

**New Colouring Matters [Cotton Blacks], Manufacture or Production of.** I. Levinstein and Levinstein, Ltd., Manchester. Eng. Pat. 17,965, Aug. 1, 1896.

THIS is an extension of Eng. Pat. 2946 of 1896 (this Journal, 1897, 136). By diazotising or tetrazotising the amido-azo dyestuffs obtained from diazotised 1,4,2-naphthylenediamine sulphonic acid and suitable amines or amidonaphthols, &c., and combining these products with phenols, amines, diamines, and the like, valuable black dyestuffs are obtained which are applicable to cotton as well as to wool. Thus 25 kilos. of amidodiazonaphthalene sulphonic acid obtained from 23·8 kilos. of 1,1,2-naphthylenediamine sulphonic acid are stirred into an alkaline solution of  $\gamma$ -amidonaphthol sulphonic acid at a temperature of about 20°—25° C. The dyestuff produced, is salted out and filter-pressed, and gives deep violet-black shades on wool. 53·2 kilos. of the product so obtained are dissolved in 600 litres of water, and the solution is diazotised in presence of ice with 70 kilos. of hydrochloric acid (18° B.) and 7·2 kilos. of sodium nitrite at a temperature of 8°—10° C. In a few hours the original dyestuff is converted into a dark-coloured diazo compound, which is run into an aqueous solution of 12·5 kilos. of *m*-tolylene diamine. The free acid is neutralised with sodium acetate, and the combination is complete after a short time. The whole is then made alkaline, and the new dyestuff is salted out, filter-pressed, and dried. It gives deep black shades on animal and vegetable fibres.—T. A. L.

**Disazo [Brown] Dyestuffs, Impts. in the Manufacture of Primary.** S. Pitt, Sutton. From L. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 17,590, Aug. 8, 1896.

THE patentees find that salicylic acid is capable of taking up two azo groups by combining derivatives like diazotised *p*-nitraniline with the easily soluble azo dyestuffs obtained from diazo sulphonic acids and salicylic acid. For example, 41·6 kilos. of the dyestuff from 2,2'-diazonaphthalene sulphonic acid and salicylic acid (which dyes wool yellow) are mixed in a dilute solution with the diazo compound from 13·8 kilos. of *p*-nitraniline, the whole being kept alkaline by means of sodium carbonate. Combination at once takes place, and the dyestuff is filtered off after a few hours. It dyes chromed wool brown. The dyestuff obtained according to this specification are fast to light and dye much more level shades than the monazo derivatives. Moreover, since they contain an azo group ortho to the hydroxyl, they are not sensitive to alkalis.—T. A. L.

**Dyestuffs [Blue] on Fibre, The Production of.** H. E. Newton, London. From "The Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 17,591, Aug. 8, 1896.

ACCORDING to Eng. Pat. 825, 4757, 6035, 6035A, and 8093 of 1893 (this Journal, 1894, 31, 245, 383, and 510), blue thiazine dyestuffs are obtained which are known as brilliant alizarin blues. In the present specification a process is described by means of which these dyestuffs are produced on the fibre by development during steaming (without:

pressure) from intermediate compounds, which are oxido-phenolthiosulphonic acids of the general formula—

For example, such an intermediate compound is formed by mixing in an aqueous solution, equimolecular proportions of sodium dimethyl-*p*-phenylenediamine thiosulphonate and 1,2,4-naphthoquinone potassium sulphonate (*vide Eng. Pat. 4757 of 1893, loc. cit.*). The product is then salted out, and, when boiled in an alkaline solution, it is converted into the corresponding brilliant alizarin blue. When printed on a fabric together with a chromium salt and steamed, the chrome lake of the colour is developed on the fibre. A solution of 3 kilos. of the above intermediate compound in 20 litres of water is stirred into 61 kilos. of a neutral starch tragacanth thickening and subsequently mixed with 6 kilos. of a chromium acetate solution (20° B.) and 10 kilos. of a 25 per cent. sodium thiosulphate solution. This paste is printed on the fabric, which is then steamed for an hour without pressure and subsequently chalked, malted, and soaped in the usual manner. The print shows a very level, bright indigo colour, fast to washing and even boiling sodium carbonate. By employing the intermediate compound from dimethyl-*p*-phenylenediamine sodium thiosulphonate and potassium 1,2,4,3'-naphthoquinone disulphonate, a print is obtained which is more greenish-blue than that above described.—T. A. L.

**Azo Dyes [Blues], Production of New.** W. H. Clans, A. Rée, and L. Marchlewski, Manchester. Eng. Pat. 18,020, Aug. 14, 1896.

THE products described are derivatives of *p*-diamines and  $\gamma$ -amidonaphthol sulphonic acid, of which the following is a typical example. The tetrazo compound from 21·2 kilos. of tolidine is added to an alkaline solution of 22·7 kilos. of 1,4-naphthol sulphonic acid, and to the intermediate compound produced there is added an alkaline solution of 49 kilos. of the amido-azo compound obtained by combining diazotised  $\gamma$ -amidonaphthol sulphonic acid with the acid itself. After agitating some time, the reaction is completed by heating to 50° C. and finally to 80° C. The product gives reddish-blue shades on cotton. If the alkaline solution be acidulated, diazotised with 7 kilos. of sodium nitrite, and combined with 12·2 kilos. of *m*-tolylene diamine, it yields a dyestuff which gives blackish-blue shades. For the production of the amido-azo compound referred to above, 21 kilos. of  $\gamma$ -amidonaphthol sulphonic acid are dissolved in 700 litres of water and the necessary quantity of sodium carbonate. The solution is made acid with hydrochloric acid, cooled with ice, diazotised with 7·1 kilos. of sodium nitrite, and run into 24 kilos. of  $\gamma$ -amidonaphthol sulphonic acid and 36 kilos. of sodium carbonate in 700 litres of water (see also Eng. Pat. 19,330 of 1890, and 9529 of 1894; this Journal, 1891, 917, and 1895, 478).—T. A. L.

**Phthalic and Sulpho-phthalic Acids, Impts. in the Manufacture and Production of.** J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 18,221, Aug. 17, 1896.

THE process consists in the production of phthalic acid and sulphophthalic acids by the action of fuming sulphuric acid on naphthalene at about 300° C. in presence of mercury sulphate, the metal itself or its oxides. About 100 kilos. of naphthalene, 1,500 kilos. of sulphuric acid (100 per cent.  $\text{H}_2\text{SO}_4$ ), and 50 kilos. of mercury sulphate are heated until the naphthalene is dissolved. The melt is then heated in a distilling vessel, and at about 200° C. oxidation commences, proceeding more rapidly at 250° C. The melt turns dark and evolves sulphurous and carbonic acids. The temperature is finally raised to 300° C. or above, until the mass becomes viscous. The distillate consists of dilute sulphuric acid, phthalic acid, partly as anhydride, and some sulphophthalic acid. The phthalic acid is filtered off, and the

residue in the retort containing the mercury sulphate can be used for another operation. In place of naphthalene,  $\beta$ -naphthol, naphthionic acid, or phenanthrene may be used. For the preparation of sulphophthalic acid, 100 kilos. of naphthalene are dissolved in 300 kilos. of fuming sulphuric acid (20 per cent.  $\text{SO}_3$ ) and mixed with 1,200 kilos. of concentrated sulphuric acid (95 per cent.  $\text{H}_2\text{SO}_4$ ). The melt is heated for 10 hours to about 250° C. A certain amount of phthalic acid distils over, and the melt is neutralised with calcium or barium carbonate and worked up in the usual way. The barium salt of a new disulphophthalic acid may be separated from water in crystalline nodules. If the temperature be maintained at about 220° C., a mono-sulphophthalic acid results.—T. A. L.

**Red Colouring Matters, Impts. in the Production of.** T. R. Shillito, London. From J. R. Geigy, Basle, Switzerland. Eng. Pat. 18,720, Aug. 24, 1896.

THE rhodamines, like the colours of the patent blue series, show a remarkable fastness to alkalis, and both contain a substituent—the one a carboxyl and the other a sulphonic acid group—ortho to the methane carbon. The present specification describes dyestuffs of the rhodamine series which contain a sulphonic acid group in place of the carboxyl and show a similar fastness to alkalis. Benzaldehyde-*o*-sulphonic acid is condensed in an alkaline aqueous solution with alkylated *m*-amidophenols. The dihydroxylated alkylamidotriphenylmethane sulphonic acids produced, are heated with dehydrating agents—for instance, concentrated sulphuric acid—and finally the triphenylmethane oxide derivatives thus formed, are oxidised to dyestuffs in an aqueous solution by means of potassium bichromate, lead peroxide, ferric chloride, or the like. The following are the quantities employed:—37 kilos. of a 10 per cent. benzaldehyde-*o*-sulphonic acid solution, 7 kilos. of diethyl-*m*-amidophenol, and 1 kilo. of sodium carbonate are boiled for 8 hours. The solution of the tetra-ethylamidodihydroxytriphenylmethanesulphonic acid is evaporated to dryness, ground, and heated with 40 kilos. of concentrated sulphuric acid for 3–5 hours at 135°–145° C., diluted with 400 litres of water, boiled, and filtered. It is then oxidised with 18 kilos. of a 33 per cent. ferric chloride solution and heated to 90°–100° C. for 4–5 hours. The dyestuff separates partly in crystals, the remainder being salted out. After washing with brine it is boiled up with aqueous ammonia, which removes products soluble in alkalis, and is finally washed with water, dried, and crystallised from alcohol. The solutions, especially the alcoholic one, show a bright yellowish-red fluorescence. Hydrochloric or dilute sulphuric acid give yellowish-red solutions which turn bluish-red on dilution. These solutions dye wool and silk pure bluish-red shades perfectly fast to alkalis.

—T. A. L.

**Dyestuffs [Yellowish-Reds] of the Phthaline Series, Process for Obtaining.** H. Imray, London. From "The Basle Chemical Works Bindschedler," Basle, Switzerland. Eng. Pat. 12,180, May 17, 1897.

By condensing diethylamido-oxybenzoyl benzoic acid with *p*-amido-*o*-cresol, valuable dyestuffs are obtained which can be alkylated, and then form salts soluble in water, dyeing tanned cotton yellowish-red shades. A mixture of 31 kilos. of diethylamido-oxybenzoyl benzoic acid, 15 kilos. of *p*-amido-*o*-cresol ( $\text{CH}_3:\text{OH}:\text{NH}_2 = 1:2:4$ ), 180 kilos. of 100 per cent. sulphuric acid, and 40 litres of water, is heated at 140°–160° C. until a sample dissolves in warm water. The melt is then poured into 1,000 litres of water and heated for some time. After cooling, filtering, and washing with water, the residue is suspended in 100 litres of alcohol and the same volume of 10 per cent. ammonia, heated, filtered, and mixed with 100 litres of 30 per cent. hydrochloric acid. On cooling, green crystals separate out, and 30 kilos. are heated under a reflux condenser with 100 litres of alcohol and 45 kilos. of sulphuric acid monohydrate for about eight hours. The melt is then poured into 1,000 litres of water, and the dyestuff is salted out with potassium bisulphate. It is purified by repeating the treatment. The dyestuff forms a yellowish-red powder, which dissolves with the same colour in water or in alcohol. In strong

sulphuric acid it dissolves with a yellow colour, whilst the ammoniacal alcoholic solutions have a yellowish-green fluorescence.—T. A. L.

*Dyestuffs of the Phthalic Series, Process for obtaining New.* H. Imray, London. From "The Basle Chemical Works, Blindschlieder," Basle, Switzerland. Eng. Pat. 12,181, May 17, 1897.

WHEN dialkylamido-oxybenzoyl benzoic acids are condensed with resorcinol, dyestuffs are obtained which, when converted into their ethers, give yellowish-red shades on wool, silk, and tannin-mordanted cotton. A mixture of 28 kilos. of dimethylamido-oxybenzoyl benzoic acid, 14 kilos. of resorcinol, 180 kilos. of sulphuric acid monohydrate, and 180 litres of water, is heated on the water-bath until the colour no longer increases in intensity. The melt is then poured into 1,000 litres of water, heated for some time, and allowed to crystallise. 30 kilos. of the dimethylrhodol, 80 kilos. of alcohol, and 75 kilos. of sulphuric acid monohydrate are heated for several hours until a complete solution is obtained. The melt is poured into water and the precipitated base is converted into the hydrochloride, which is purified by crystallisation from water containing hydrochloric acid.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENTS.

*Fibre, Paper, Tissues, and the like: Impts. in the Method of Waterproofing Fabrics made of.* J. Waugh, Bradford, Yorkshire. From Amos and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 15,893, July 18, 1896.

*"Mercerising" Fabrics composed of Vegetable Fibres. Impts. in the Process of what is known as.* F. A. Bernhardt, Zittau, Germany. Eng. Pat. 16,840, July 29, 1896.

DURING the process of mercerising, the fabric is wrapped on a hollow perforated cylinder and subjected to the pressure of a solid roller placed above the cylinder. The mercerising solution is forced through the fabric from the interior of the cylinder. It is necessary to continue the rolling pressure for some time in order to counteract the tendency of the fabric to shrink during mercerisation.

—R. B. B.

*Degreasing Wool, Cotton Waste, and other Fibrous Materials; Impts. in Apparatus for.* F. N. Turney, Nottingham. Eng. Pat. 18,360, Aug. 19, 1896.

THE patentee describes a method of feeding material to, and withdrawing it from the apparatus, without admission of air or loss of the vapour of the volatile solvent. The receiving and degreasing chambers are connected by a flat tube or channel closed towards the degreasing chamber by a valve. At its other end the tube is provided with a series of stuffing boxes, through which work plungers.

The material is fed into the tube and is compressed by means of the plungers, which force it forward into the degreasing chamber, the material thus forming a plug and preventing the escape of vapour. For cleaning out the tube, a rod and cross-bar are attached to the plungers.—R. B. B.

*Rendering Substances [Wood, Woven Fabrics, &c.] Incombustible, Impts. in.* A. Issel, Genoa, Italy. Eng. Pat. 11,368, May 7, 1897.

See under IX., page 681.

*Loading or Sizing Silk, An Impt. in.* L. Hwass, Crefeld, Germany. Eng. Pat. 13,425, May 31, 1897.

It is claimed that in the weighting of silk by means of stannic chloride, sodium phosphate, and sodium silicate, the tendering action of the weighting agents is greatly diminished by the introduction, between the baths of sodium phosphate and sodium silicate, of a bath containing a soluble copper salt for dark colours or a soluble zinc salt for pale shades.—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Indigo Vats, Improved.* J. Grossmann, J. Soc. Dyers and Colourists, 1897, 130—131.

IN indigo vats of any kind, portions of the indigo are constantly being regenerated, and thus precipitated, by the oxygen of the air carried through the liquid by the cloth, and thus require constantly fresh additions of the reducing agent. Owing to this circumstance, there is a large accumulation of sediment or of foreign matters in solution, according to the kind of vat used, which tends to weaken the vat. To obviate this defect, the author prepares his vats, in the first instance, with "indigo white," thus entirely dispensing with the reducing agent at the "setting" of the vat, and during working adds small quantities only of the latter, corresponding to the quantity of indigo that is regenerated, to keep the vat in condition. In this manner a vat can be worked with  $\frac{1}{2}$  lb. of the reducing agent that would otherwise be required, giving much better results, whilst greatly minimising the risk of loss of indigo by over-reduction.—I. S.

*p-Nitraniline Red Discharge on Indigo.* R. J. Flintoff, J. Soc. Dyers and Colourists, 1897, 132—134.

C. KUNZ has proposed a process for a *p* nitraniline red discharge on indigo (J. Soc. Dyers and Colourists, 1897, 90), which consists in padding the indigo-dyed cotton with sodium  $\beta$ -naphtholate, to which some potassium chromate has been added, drying and printing on the thickened solution of the diazo compound *plus* lead acetate. Proceeding in this manner, the chromic acid required for the destruction of the indigo is retained on the cloth as lead chromate, whilst the remaining chrome salt is removed during the subsequent washing process.

The author now submits a cheaper and simpler process for the same purpose. The indigo-dyed cloth is prepared with an alkaline solution of  $\beta$ -naphthol in the usual manner, and to the diazo nitrobenzene acetate is added the requisite quantity of sodium bichromate, which has no action on the diazo compound. The best proportions are 1,800 grms. of sodium bichromate to 1.5 litres of printing colour. The goods are dried on the drying cylinders, passed through a bath containing sulphuric and oxalic acids, well washed in cold water, and soaped at 120° F. for 10 minutes; again well washed, and dried.—I. S.

*Wool Mordants, Tungsten and Molybdenum as.* E. Knecht, J. Soc. Dyers and Colourists, 1897, 135.

THE author has tested the value of tungsten and molybdenum as mordants on wool. The wool was boiled for an hour with 3 per cent. of sodium tungstate alone, and also with 3 per cent. of tungstate and 1 per cent. of sulphuric acid, after which it was well washed. The wool, which thus acquired a yellowish tinge, was then dyed, under the usual conditions, with the following dyestuffs: logwood, fustic, coerulein, alizarin, and gallocyanine. Full colours were thus obtained, the shades of which lie between those obtained on stannous and on chrome mordants, better results being obtained with sulphuric acid than without. But their fastness to light and to soap were not satisfactory.

With molybdenum the same mode of procedure was employed as for tungsten, the tungstate being replaced by ammonium molybdate. With molybdate alone the colour of the wool was not materially changed, but with an addition of sulphuric acid, the wool was coloured dull blue. In dyeing with the same colours as used for tungsten, shades were obtained which closely resembled those obtained with potassium bichromate, their fastness to light and soap being satisfactory.—I. S.

### PATENTS.

*Solid Paste or Soap Compound for Dyeing all kinds of Textile Materials, Manufacture of a.* C. Uffelmann, Kassel, Germany. Eng. Pat. 17,382, Aug. 6, 1896.

A SUITABLE soap with an equal weight of the required aniline colour, is dissolved in an excess of alcohol, and

added to an aqueous solution of the mordant mixed with glue, gelatin, or other binding material. After the addition of glycerin to the amount of one-third of the weight of the soap, the mixed solutions are at first gently heated, and then the temperature raised gradually until the mass has become homogeneous, and about two-thirds of the alcohol have been distilled off. The mass is then poured out, and, when cold, is cut into cakes, which are soluble in hot water and at once ready for dyeing textile materials. Although containing as much as 50 per cent. of soap, the paste does not become decomposed, owing to the large amount of mordant present.—C. A. M.

*Mordanting Wool and other Animal Fibre, Impts. in the Process of.* A. M. Clark, London. From C. H. Boehringer Sohn, Niederrhein-on-Rhine, Germany. Eng. Pat. 18,896, Aug. 26, 1896.

A MORDANT is described consisting, for 100 kilos. of wool, of 2.65 kilos. of lactic acid (50 per cent.), 1.35 kilos. of potassium bichromate, and 0.9 kilo. of sulphuric acid, in a bath of 2,000 litres of water. The wool is entered at 160° F. and worked for half an hour; the bath is slowly heated to the boil and maintained at boiling point for half an hour. It is claimed that a complete reduction of the bichromate takes place, that the bath is completely exhausted, and that the shades are purer and faster and the fibre less affected than when other mordants are employed.

—R. B. B.

*Artificial and Natural Colouring Matters, Process of Preparing Solutions of, for Dyeing and Printing Purposes.* W. Clark, London. From C. H. Boehringer Sohn, Niederrhein-on-Rhine, Germany. Eng. Pat. 21,211, Sept. 24, 1896.

MANY colouring matters—e.g., induline and indigo—which are insoluble or only soluble with difficulty in ordinary solvents, are readily dissolved in lactic acid or its acetyl derivatives and esters. Such solutions, it is claimed, are useful for printing on cotton or woollen fabrics, for dyeing silk, and other purposes.—R. B. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Thirty-third Annual Report on Alkali, &c. Works, by the Chief Inspector.* May 7, 1897.

THIS, Mr. R. Forbes Carpenter's second Report, shows only slight variations in the number of works registered under the Act, and in the scheduled processes of manufacture. The most notable differences are: an increase of the salt processes of from 52 to 58 as compared with 1895; and in the fibre-separation processes an increase of from 38 to 44; while arsenic processes have diminished from 14 to 37. Alkali works have diminished from 101 in 1895 to 93 in 1896, but "other works" are increased from 964 to 976. The escape of acid gases, reckoned in grains per cubic foot of total gases, does not materially differ from that of 1894-95; but the hydrochloric acid escaping as compared with that produced, which in 1895 was 1.714 per cent., is for 1896 only 1.411 per cent. The "acidity of all chimneys" given as grains of  $\text{SO}_3$  per cubic foot, was 0.709 in 1895 and 0.803 in 1896. The acidity of gases from manure works is slightly diminished as compared with the preceding year.

The following table is given of the—

*Salt decomposed in the Leblanc and Ammonia-Soda Processes (including Scotland).*

	1896.	1895.	1894.
Tons.			
Leblanc process.....	360,929	408,173	444,298
Ammonia-soda process.	431,577	428,614	361,663
Total .....	792,506	836,787	795,961

From this it will be seen that the relative positions of the Leblanc and ammonia-soda processes for 1894 and 1896 are almost exactly reversed.

Over the period covered by the Report, the manufacture of caustic soda and chlorine by electrolysis has been chiefly experimental, but progress was made at the works of the Castner-Kellner Alkali Company for starting in the present year, and the Hargreaves-Bird electrolytic process is to be conducted at Channy by the St. Gobain Company. In the manufacture of chlorate of soda, Mr. J. Hargreaves has applied on a large scale his process for chlorinating hydrated sodium carbonate directly, in an absorbing tower, in which lixiviation of the products to remove sodium chloride is also conducted, the intermediate production of calcium or magnesium chlorate being avoided. In France, Germany, Switzerland, and Sweden, it is stated that processes for the direct electrolytic formation of chlorates have received wide extension. Processes for obtaining chlorine simultaneously with zinc or copper by the electrolysis of zinc or copper chlorides do not appear as yet to have been tried on a large scale, although the Inspector considers that "Dr. Hoepfner's processes, as regards the extraction of zinc, will be tried in the first instance by ammonia-soda manufacturers, to whom indeed they would strongly appeal, as offering a promising means of rendering available the chlorine of the calcium chloride solution now run to waste in such enormous quantities." A nitric acid chlorine process has been successfully carried out in Middlesbrough, bleaching powder of the highest strength having been produced; but there is a serious drawback in the cost of concentrating the large quantities of weak sulphuric acid resulting from the decomposing operations. It is suggested that the Kessler plant for rectifying the acid would prove serviceable.

The continuous processes adopted for rectifying sulphuric acid in glass, porcelain, or enamelled iron beakers, stepped in series, have not given entire satisfaction to the Inspector, owing to the liability to the escape of acid by breakages or corrosion; and not only is a grave warning given, but a suggestion is made that some amendment of the Act of 1881 may be needed, to reduce the "maximum acidity" permitted under section 8. The "Kessler" rectifying plant, however, is described as working well and with great regularity. An acid of about 97 per cent. monohydrate is produced, not of the best "colour and brightness," but well suited for application in nitrating and in some other operations. In Scotland, the production of sulphuric acid has been active, notwithstanding the restricted condition of alkali works, as is shown by an increase of the quantity of pyrites burned of 1,817 tons over the preceding year.

The loss of ammonia in the production of soda-ash (ammonia-soda process) has been reduced, but is still equal to 2.0 per cent. of sulphate per ton of 58 per cent. alkali, which is equivalent to the loss of 5,395 tons of sulphate of ammonia for 1896. An increasing amount of ammonia is used in the manufacture of cyanides. The following table is inclusive of ammonia, either lost, or applied in manufacture without going upon the market:—

*Amount of Sulphate of Ammonia produced in the United Kingdom.*

	1896.	1895.	1894.
Tons.			
Gasworks .....	127,498	113,045	113,634
Ironworks .....	16,511	14,583	10,075
Shale-works .....	37,822	38,353	32,891
Producer-gas, coke, and carbonising works.	9,078	7,083	3,448
Total .....	190,909	173,061	160,048

It is observable that the ammonia from gasworks has not increased so much as might have been expected from the increased production of gas. This is attributed to the introduction in part of the gas derived from the interaction of incandescent coke and steam, from which no ammonia is obtained. In America this displacement of coal-gas has reached more than 70 per cent.; and it is anticipated that the displacement will go on here at an increasing rate, even if there be more danger of poisoning from carbon monoxide

with the water-gas than with the coal-gas. There is a prospect, however, that the supply of ammonia from other sources will be increased. In the large ironworks at Merthyr and Dowlais, in South Wales, where hitherto by-products have not been collected, changes in the machinery make it probable that in the future tar and ammonia will be recovered. The successful development, also, of Dr. Mond's process for recovery of ammonia from gaseous fuel used in melting steel is referred to. In shale distillation, the introduction of the "Pentland" retort of Messrs. Young and Beilby, in 1884, appears to have been the means of the salvation of the Scotch oil trade, which has for many years been subjected to "severe stress of competition" from the American and Russian supplies. An improved form of the Pentland retort has been introduced during the year, for which it is claimed that no additional fuel for distillation is required beyond the gases derived from the retort itself.

The experiments conducted at the works of the Luton Gas Company, in using oxide of iron purifiers, with concurrent revivification by regulated steam and air admission, have been continued during the year, and a table is given of the results of analyses of the samples taken. Artificial oxide gave a very prolonged run without fouling, but the working throughout shows loss of available sulphur. Mixed Flitwick and Irish bog ores gave better results than the Flitwick used singly. In another works, where the method of alternate downward revivification, without steam, is in use, with three hours' spells of work, a sample of oxide from the lower part of the purifier, worked for six months, gave 55.66 per cent. of total sulphur, of which 82.3 per cent. was free or available.

A new change valve has been introduced at the Richmond Gas Company's works, which is easy to lift and turn, and at no time is the foul gas main unsealed, so that no escape of hydrogen sulphide can take place during change. A drawing is given.

An elaborate investigation into the constitution of ammoniacal liquors has been conducted, the results of which are tabulated, and the methods of analysis used are described. High commendation is given to Mr. F. Lennard's continuous tar still, two units of plant of which deal daily with 16,000 and 24,000 galls. of tar respectively. The freedom from nuisance is said to be absolute, and "the pitch is delivered in a constant stream, which can be cooled to any desired degree before appearing in the open on the pitch bays." One plant is already at work on the Continent, and another is being erected in Scotland.

The Report consists of 118 pages, 11 of which are devoted to Scotland. No. 4 district has been divided into two portions: one, North and East Lancashire, under Mr. Porter; and the other (4A), East Midland, under Mr. Fletcher.

—E. S.

#### *Percarbonate of Potassium: Its Preparation and Properties.*

A. v. Hansen. Zeits. f. Elektrochem. 1897 3, 445—448.

THE author (with E. J. Constam. This Journal, 1896, 815) has already given a description of the preparation of potassium percarbonate by electrolysis a concentrated solution of potassium carbonate at a low temperature. The clear solution in the neighbourhood of the anode becomes milky, owing to the separation of percarbonate, and by filtering off, a salt of sky-blue colour is obtained. This is potassium percarbonate, containing a few per cent. of potassium carbonate as an impurity. Further experiments have now been made to ascertain the best conditions for successful preparation. The electrolysis was carried out in a porous cell of 200 c.c. capacity, placed in a beaker of such size that the outer cell gave about 120 c.c. as anode space. The anode was a platinum spiral, the cathode of sheet nickel.

**I. Influence of Temperature.**—If the electrolysis is started at about  $-15^{\circ}\text{C}$ ., small variations of temperature have but little effect on the yield, provided the anode liquid is kept concentrated. The temperature may even rise to  $0^{\circ}$  without much effect upon the reaction. But if the specific gravity of the potash solution fall below 1.52, the yield diminishes rapidly as the temperature rises. Thus the temperature should be kept low towards the end of the reaction, when the solution has become weaker owing to separation of percarbonate.

**II. Influence of Concentration.**—If the concentration of the anode liquid drop even slightly below the saturation point, little or no percarbonate is obtained, for the substance is extremely soluble in dilute solutions. Furthermore, in dilute solutions potassium bicarbonate is produced and forms the greater part of the crystalline precipitate obtained.

**III. Influence of Current Density.**—A high current-density is of the greatest importance, otherwise much bicarbonate is formed. Finally the author recommends that special care should be taken to ensure high current-density and concentration of the solution; the employment of temperatures as low as  $-10^{\circ}$  and below, is not necessary if the solution be always kept saturated. A saturated solution of pure potash at ordinary temperatures has a sp. gr. of 1.555 or 1.556, and it is a remarkable fact that such a solution exhibits no tendency to crystallise out when its temperature is lowered. On the other hand, a concentrated solution of commercial potash rapidly deposits crystals when it is cooled a few degrees below zero. In order to prevent the separation of crystals inside the porous cell, it is well to use as the cathode liquid a less concentrated solution. The method above described is not well adapted for preparing percarbonate in quantity; for this purpose the following modification is recommended.

The outer vessel is provided with an outflow tube at a level just below the rim of the porous cell. As the electrolysis proceeds, and in proportion to the amount of percarbonate formed, fresh solution is introduced into the lower part of the anode space by means of a funnel. The specific gravity of the electrolysed fluid is less than that of the fresh potash solution; hence the two do not mix. The solution containing the percarbonate rises and flows away through the outlet and is at once filtered. The yield per ampere-hour is from 2.2 to 2.4 grms. of solid salt containing 87 to 93 per cent. of percarbonate. After all adhering liquid is pumped away, the salt is spread on a porous plate and dried in a current of dry air. This works much more rapidly than drying in a desiccator. Towards the end of the operation the air can be heated to about  $40^{\circ}$ ; above this, decomposition sets in. The salt thus prepared is an amorphous powder with a slightly blue colour. The pronounced blue colour of the moist salt disappears almost entirely on drying. It is easily decomposed, yielding up oxygen to oxidisable bodies. But it is not so unstable as was at first supposed. In order to decompose it in a short time by heating, a temperature of  $200^{\circ}$ — $300^{\circ}$  is requisite. On immersion in water it only slowly decomposes at ordinary temperatures. But at somewhat higher temperatures it rapidly decomposes with evolution of oxygen; in fact, it is a convenient laboratory source for preparing pure oxygen. The salt has only to be placed in water and warmed to about  $45^{\circ}$ ; a very steady current of oxygen then comes off. The reaction goes on of itself without need of any further heating, and scarcely a trace of percarbonate is left. 100 grms. of the salt give about 5 litres of oxygen. In order to retain any carbon dioxide that may be developed, soda is added to the water.

Like the peroxides of sodium, barium, and hydrogen, it can be used as an oxidising agent. By adding it to diluted acids a more or less concentrated solution of hydrogen peroxide is obtained. If an excess of acid be present, the solution keeps well. The dry percarbonate keeps very well, and is a convenient source for rapidly preparing a solution of hydrogen peroxide. Potassium percarbonate cannot be crystallised from its aqueous solution. If water at  $0^{\circ}$  be saturated with it and then cooled to  $-15^{\circ}$ , a rich crop of crystals separates out, but these consist mainly of ice. It is, however, only slightly soluble in alcohol; and by making use of this property it can be purified as follows. An excess of the salt is added to a strong solution of caustic alkali and is digested with it for some time at  $-5^{\circ}$  to  $-10^{\circ}$ . The bicarbonate contained in the salt is decomposed by the alkali. The potash produced goes into solution, and, after filtering, we obtain percarbonate containing only a small quantity of caustic alkali as impurity. By treatment with absolute alcohol this is removed and a product containing 95 to 99 per cent. of percarbonate is obtained. The author

has not succeeded in preparing the sodium or ammonium salt of percarbonic acid.—D. E. J.

*Barium Sulphocyanide from Spent [Gasworks] Oxide, Manufacture of.* V. Höbbling. Zeits. angew. Chem. 1897, [10], 297.

If pure Prussian blue be boiled for a short time under a pressure of 2 or 3 atmospheres with a very large excess of barium sulphide, or with a small excess of barium sulphide and some free sulphur, it is converted into barium sulphocyanide according to the following reactions:—

As spent oxide naturally contains a large amount of sulphur, it is only necessary to add some 10 or 15 per cent. excess of barium sulphide and to boil it for half an hour at a pressure of 3 atmospheres in order to recover the whole of the blue as thiocyanate. The filtered liquid requires purification from barium sulphide; and this may be effected either by treatment with sulphurous or carbonic acid gas. In the former case the sulphide is chiefly converted into the insoluble thiosulphate of barium and free sulphur, a small quantity still remaining in solution as sulphite, which may be removed by decantation after the liquor has been evaporated till its specific gravity reaches 1.38. The barium thiosulphate is heated until it splits up into sulphide and sulphur, and it is then ready for use over again. If carbonic acid be employed to decompose the barium sulphide, the sulphuretted hydrogen is absorbed in the usual manner, the resulting carbonate converted into sulphate, and the latter ignited with coal to form fresh sulphide.

The purified sulphocyanide solution is evaporated to a density of 1.75 to 1.79 and allowed to crystallise, the yield being sufficiently pure for use by dyers without further treatment.—F. H. L.

*Acetic Bacterium, A New.* Zeidler. Zeits. für Spiritusind. 1897, 20, [20] and [21], 164 and 171—172.

## PATENTS.

*A Still or Tank for the Distillation, Boiling, and Holding of Acids, Alkali, and other Corrosive Liquids.* D. Bray, Cinderford, Gloucester. Eng. Pat. 16,877, July 30, 1896.

See under I., page 661.

*Hydrochloric Acid, Impts. in the Manufacture of, Free from Arsenic.* J. R. Wyld, J. W. Kynaston, and J. Brock, Liverpool. Eng. Pat. 17,607, Aug. 8, 1896.

HYDROCHLORIC acid gas resulting from the treatment of sodium chloride with ordinary sulphuric acid containing arsenic, is taken through a length of pipes, and, with addition of a little chlorine, is passed through a "dry tower," charged with coke or the like. The temperature of the gases passing through the tower should not exceed 55° C., under which condition the small quantities of hydrochloric acid and steam which condense to liquid acid upon the coke, retain practically all the arsenic present, converted into the comparatively fixed condition of arsenic acid under the influence of the added chlorine. The arsenic-free gas issuing from the dry tower is passed through an ordinary condensing or "wet" tower, down which water is passed, to obtain the acid.

The gases issuing from the "decomposer" in Deacon's chlorine process, containing hydrochloric acid, chlorine, aqueous vapour and nitrogen, &c., are arsenical, and, after passage through cooling pipes, are taken successively through the dry and wet towers as described, to obtain a liquid acid free from arsenic. Any trace of chlorine remaining in the product, may be removed by passing air through the cold acid, or by addition of a deoxidising substance such as ferrous chloride.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

### PATENTS.

*Sulphate Glass, Manufacture of.* K. W. R. Goerisch, Dresden, Germany. Eng. Pat. 14,901, July 6, 1896.

To the glass batch are added fats, oils, resins, ceresin, or paraffin. All these matters are said to contain in an eminent degree hydrogen, in a form capable of reducing the sulphate of the sodium sulphate in the glass batch, to sodium sulphite, which is then quickly decomposed by the silica.—E. A.

*Enamelled Ceramics with a Slaggy Biscuit, covered over with Coloured Enamels, Manufacture of.* H. De Wit, Euphrasie, Belgium. Eng. Pat. 10,430, April 27, 1897.

SLAG of any kind, whether of refining, moulding, or steel, will do. It is agglutinated by clay or plastic earth, so that the biscuit may contain 50 per cent. of silica, 25 per cent. of calcium carbonate, and 20 per cent. of alumina. The complete baking of the product may be accomplished in one or several operations.—E. A.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Blast-Furnace Slag that has been treated with Nitric Acid, as an Addition to Hydraulic Cement.* A. D. Elbers. Eng. and Mining J. 1897, 63, 661.

A PROCESS has been patented (U.S. Pat. 579,820, March 30, 1897), with the object of removing the objectionable calcium sulphide from, and otherwise improving the blast-furnace slag, used as a constituent of cement. The furnace slag to be improved is moistened with a weak solution of finely ground slag is moistened with a weak solution of nitric acid, more water added when the acid is neutralised, and the leached mass dried. The complete treatment requires about  $\frac{1}{2}$  lb. of 60 per cent. nitric acid and 30 lb. of water per 100 lb. of slag.

The author arrived at the following conclusions with regard to the efficiency of slag treated as above:—High-class Portland cements—those which have been ground from carefully prepared stock that has been burned very hard—can only be improved by the admixture of small quantities, say, not exceeding 10 per cent. on the average. Inferior Portland cements may be mixed with about the same weight of the above-mentioned slag, and still give a good result as the neat. Briquettes made up of cement, slag-treated as described, and sand, give rather poor compressive results as regards their test for tensile strength, when the sand is added after the cement and the slag has been thoroughly wet-mixed. It is suggested that a fairer test would be to slurry the mixtures, just as is done in work, cement for the "second set," and to fill the slurry into moulds without heating it.

A briquette, made by casting the mixture into the mould, and composed of 90 per cent. of high-class Portland cement and 10 per cent. of the prepared slag, the water added being 30 per cent., broke when 17 days old at 350 lb. tensile strain per square inch.—A. S.

*Building Materials, Testing.* Mitt. k. t. Versuchsanst. zu Berlin, 15, [1], 80—85.

1. *Defective Flooring Tiles.*—The upper surface of the tiles consisted of chippings of white and yellow-brown marble, cemented together by a greyish-black cement, and the defect complained of was the appearance of a number of small bubble-like cavities in the mass, which, on examination, proved to be due to imperfections of manufacture, since they were not caused by the dislodgment of any of the particles of marble—as the fact of their underlying many of the latter demonstrated; nor were they the result of washing with acid, as was proved by the fact that both concentrated and dilute hydrochloric acid dissolved the marble much more rapidly than the cement.

2. *Badly Mixed Concrete.*—(a) A sample was submitted for examination on account of its having become

brittle and perished, although only 2—3 years old. The proportion of cement to sand and gravel was ascertained to be 1:10, and the composition of the former to be that of normal Portland cement. An examination of the ratio of sand to gravel, however, indicated that the latter was in such excess that the interstitial spaces were incompletely filled, and also that, assuming the deficiency to have been made good by the use of cement, the ratio of cement to sand and gravel should have been 1:4.1 instead of 1:10, i.e., that an increased quantity of sand ought to have been employed.

(b.) Defective concrete pipes formed the subject of another examination. The load required to break the pipes was found to be only 1,713 kilos., whereas other pipes of the same dimensions (105 cm. long, 50 cm. wide, and 6 cm. thick) required for that purpose, on the average, a load of 3,867 kilos. According to analysis, the ratio of cement to gravel was normal (1:3.45), but the latter contained carbonates, and when washed by sedimentation exhibited a large number of snail-shells, the water running away being very turbid and indicating impure materials. Other impurities present in large quantity were: moss, leaves, grass, shives, and more or less rotten wood, thus explaining the defective condition of the pipes.

3. *Unsuitability of Sugar-Works Sediment for Mortar Making.*—A specimen of waste lime from sugar works was found to be fully saturated with carbonic acid and organic acids, and although, when mixed with three parts by volume of building sand, the blocks of mortar exhibited a tensile strength of 1.64 kilos. per sq. cm., and a resistance to compression of 7.2 kilos. after 14 days—i.e., about the same as normal mortar—the same tests applied the 24th day after moulding gave only 1.45 and 8.4 kilos. respectively, or a considerable inferiority; and, in fact, no better result than would ensue from the cohesion of earth or mould in drying.

*Streets, Roads, Pavements, and the like, and on the Surfaces of Wood and Metal; An Improved Composition for Use on.* S. P. Davies, London. From G. Frederick, Sydney, N.S.W. Eng. Pat. 15,316, July 10, 1896.

COAL-TAR or pitch is heated for 2—4 hours at 350° F., till the specific gravity is about 1.261, when an equal quantity of "retorted shale," or shale treated in a retort, or ash of shale or coal in fine powder, is added slowly. The mixture is applied to the surfaces to be covered in the usual way.

—O. H.

*Hardening Stone, An Improved Process for.* T. R. Jones, Kensington, London. Eng. Pat. 16,892, July 30, 1896.

THE process consists in placing the stone in a vacuum, and thus exhausting the air contained therein, and, whilst in the vacuum, introducing a solution of zinc sulphate, which readily penetrates the stone. The sulphate of zinc is said to combine with any lime present, and to harden the stone to the extent of the penetration.—E. A.

*Rendering Substances [Wood, Woven Fabrics, &c.] Incombustible, Impts. in.* A. Issel, Genoa, Italy. Eng. Pat. 11,368, May 7, 1897.

THE wood or other material to be rendered incombustible, is thoroughly dried, and then kept for many hours in a boiling solution of stated proportions of boric acid and potash alum; or in the case of resinous woods, of boric acid, oxalic acid, and potassium carbonate. The solution for pasteboard contains boric acid, potash alum, and glue. The treated material is well dried.—E. S.

## X.—METALLURGY.

*Structural Steel: Relation of Tensile Strength to Composition.* Engineer, 84, July 23, 1897, 84.

A SIMPLE and easily remembered rule for ascertaining the relation of tensile strength to the composition of structural steel was recently brought to the notice of the American Society of Civil Engineers by Mr. A. C. Cunningham. It is as follows:—To find the approximate tensile strength of structural steel, to a base of 10,000 lb., add 1,000 lb. for every 0.01 per cent. of carbon, and 1,000 lb. for every 0.01 per cent. of phosphorus, neglecting all other elements in normal steels. Radical variations between calculated and actual strength indicate mixed steels, segregation, incorrect analyses, or unusual treatment in manufacture.

*Silver-Copper Alloys.* F. Osmond. Comptes Rend. 124, 1234—1237.

IN a former note the author stated that the microscopic appearance of silver-copper alloys, save those containing a very minute proportion of one ingredient, suggested a mixture of two components, apparently the metals themselves. The fact that the physical properties of the alloys, however, are far from being the mean of those of the metals throws doubt on this; and microscopic examination of alloys of known composition, in which a camera lucida drawing was made of a section of each button after heating to an annealing temperature to tint the copper, and the relative amounts of the two visible constituents estimated by measuring their areas on the drawing, showed that the accessory metal (the alloys went up to 4 per cent. of either metal) was always visible in much less than its true proportion. Careful microscopic comparison of these alloys with the pure metals showed that only after about 1 per cent. of silver (or copper, as the case may be) is reached, does the metal actually begin to separate out on cooling; whence the author supposes silver and copper to be mutually soluble to a limited extent.

Polished plane surfaces of silver and copper brought into contact, and heated in hydrogen for an hour to 650°—675° C., adhered so strongly, that the fingers could not separate them, and the surfaces after separation showed to some extent the characteristics of the silver-copper and copper-silver alloys.—J. T. D.

*Aluminium, The Smelting of.* Chem. Zeit. 21, [42], 415.

IN aluminium castings, a distinction must be drawn between castings which are practically finished on leaving the mould and castings which are subsequently subjected to a forging or rolling process. The difficulty of producing sound aluminium castings, lies in the great contraction of the metal on cooling. This difficulty can be overcome by adding phosphorus to the molten metal, in the proportion of about 1 gm. to 1 kilo. Thoroughly sound castings are in this manner obtained, but they are rather brittle and therefore unfit for rolling purposes. Castings suitable for the last-named process are obtained by pouring some rape oil upon the surface of the metal, which is fused in iron crucibles. When all the oil is burnt off, the metal is run into the hot iron moulds, and as soon as the contraction begins, more metal is added. The ingots obtained in this manner are excellent for rolling, forging, or wire-drawing purposes. Aluminium fused in graphite crucibles always has a tendency to crack in the rolling or forging, the more so the oftener it has undergone the process of melting in this kind of crucible. This appears to be due to the fact that aluminium takes up silicon from the crucible.

### PATENTS.

*Iron and other Metals, A New Process and Apparatus for the Direct Production of from their Ores.* A. Karyscheff and S. Demmenie, St. Petersburg. Eng. Pat. 6654, March 26, 1896.

THE ores are brought into the condition of pyrochemical solutions, which are then subjected to the separate or combined action of heat, chemical reagents, or electricity. The method is applicable to all metals and alloys.

For the production of iron, the charge is so arranged as to produce easily fusible slags that will readily dissolve oxide of iron, and particularly pyroxenes such as hedenbergite, diopside, or augite. If the ore contain phosphorus, dolomite is added. When compounds resembling libenite and phosphorocalcite are formed with a proper preparation of the charge, it is easy to convert all deleterious admixtures into slags, and to obtain metal of excellent qualities.

In some cases the ore is dissolved in, and the metal separates out from, these fused slags by the agency of heat alone; in others, a metallic compound, rich in combined carbon, is added, and, in addition, electricity of high tension may be employed.

Any kind of furnace may be used, but preference is given to those constructed on the regenerative system and heated by producer-gas, water-gas, or acetylene; oxygen, or air rich in oxygen, is also employed in some cases to produce a higher temperature.—J. H. C.

*Ores [Iron], Impts. in the Treatment of, for the Production of Iron, Steel, and other Metals.* R. F. Strong, London. Eng. Pat. 24,657, Nov. 4, 1896.

IN order to bind together friable ores and to enable them to be smelted more successfully, the crushed ore is mixed with about 5 per cent. of crushed lime, and 10 per cent. of tarry pyroligneous acid, pressed into blocks, and conveyed direct to the furnace. Carbonaceous material and fluxes may also be added. Or a larger quantity (20–30 per cent.) of pyroligneous acid may be used if it is intended to serve as a fuel.—W. G. M.

*Iron, Apparatus for the Preliminary Fixing of.* R. M. Daelen, Düsseldorf, Germany. Eng. Pat. 10,989, May 3, 1897.

A TROUGH-SHAPED side-blowing Bessemer converter is mounted on trunnions and supported on rollers carried by a truck-frame running on rails. The air is passed through one trunnion (connection being made by a trumpet-mouthed delivery pipe) to the blast box, on one side of the converter; two rows of tuyères are superposed, but only one row is used at a time, the others being plugged. This allows for a fairly constant depth of blast delivery, in spite of variations in the capacity of the converter owing to the wear of the lining. Above the blast box is a hopper with a simply regulated valve for the admission of iron ore to be injected by the blast. On the middle of the side of the converter, opposite the tuyères, is a spout, through which the melted iron is charged and discharged. The usual rotating mechanism is attached to the free trunnion. By adopting this form of converter, the use of an intermediary ladle between the fixing furnace and the open hearth is dispensed with; the air may be introduced quite close beneath the surface of the bath, and the apparatus, with a maximum width of 1 to 1.5 metres, may contain from 10 to 20 tons of crude iron; the apparatus is in equilibrium as far as possible during rotation; the distance from the charging opening to the bottom point of the hearth is relatively very small, although the usual hood is provided, to prevent splashing during the blow; and the discharge spout may be lowered to within 800 mm. of the line of rails in front of the open-hearth furnace, so that the latter may be charged direct.—W. G. M.

*Alloys, Impts. in the Manufacture of.* A. G. Street, Paris. Eng. Pat. 12,467, June 6, 1896.

THE object of this invention is to obtain alloys of chromium, molybdenum, tungsten, uranium, and other easily oxidisable metals having a high melting point, with other metals, such as aluminium, having comparatively low fusing points.

The "infusible" metal or alloy is mixed or covered with melted cryolite and borax or other suitable flux, and then dropped into the fused metal; or the fused metal is poured over the mixture of "infusible metal and flux."—J. H. C.

*Alloy, New Metallic.* [Al, Sn, Zn.] G. Duceau, Toulouse. Eng. Pat. 15,699, July 15, 1896.

FOR ordinary parts of machinery the alloy is composed of: aluminium, 30; tin, 20; and zinc, 50 parts.

For parts subject to friction: aluminium, 15; tin, 10; and zinc, 75 parts.

In some cases a little copper is added.—J. H. C.

*Alloy, Improved Metallic.* W. T. Sugg, Westminster. Eng. Pat. 16,831, July 29, 1896.

AN alloy which will not be discoloured or otherwise deleteriously affected by the action of acids or other products resulting from cooking operations, may be made by fusing 10 parts of aluminium with 1 of silver, and adding the resulting alloy to 89 parts of molten copper. The alloy is hard, tough, and homogeneous, and may be rolled or hammered.—W. G. M.

*Chromium and similar Metals, Impts. relating to the Fusing of, and to the Manufacture of Alloys of such Metals.* E. A. G. Street, Paris. Eng. Pat. 12,396, June 8, 1896.

THE crucibles are lined with a fused mass composed of borax, cryolite, chloride of sodium, or fluoride of calcium, or a mixture of these bodies, and the oxide of the corresponding metal.—J. H. C.

*Ores, Gold and Silver; Processes and Apparatus for Classifying, Amalgamating, and Cyaniding.* J. Garnier, Paris. Eng. Pat. 14,493, June 30, 1896. (Under Internat. Convention.)

THE finely divided ore is placed in a large cylindrical iron tank provided with a perforated false bottom, which is arranged to act as a piston with the aid of a subsidiary piston and cylinder placed beneath the apparatus. The false bottom is covered with coarse, heavy particles of gold ore, or of iron or lead, to act as a filter; and the cylinder is loosely covered with a plate from which depend strips of amalgamated copper. Beneath the false bottom is a lateral connecting tube communicating with a second smaller cylinder, having a closely fitting cover carrying a rod with amalgamated copper plates attached, dipping almost to the bottom of the vessel. At the top are two side tubes with stop cocks, one above the other, the upper one communicating with the air, the lower with a steam generator. Water being introduced first into the two cylinders, the ore is introduced into that which has the false bottom, the air-escape cock in the other cylinder being left open. This is at length closed, and steam is admitted through the lower one, until the mass of ore and water in the first cylinder has been raised to some extent; the steam is then shut off, and the ore subsides, becoming partially classified in the process; the operation is then repeated several times. Finally the water, with slimes in suspension, is expelled into a second apparatus by means of the piston. A part of the gold is caught on the plates and a part is dissolved in the liquid, if cyanide solution be employed instead of water. The apparatus for treating the slimes is somewhat similar, and consists of two cylinders, connected by an inclined tube. In the first a solid piston is used, and this carries an upright with amalgamated plates attached; the second cylinder is like that employed for treating the original ore, and the process is similarly conducted. The gold is in part caught by the amalgamated plates, and in part is dissolved by the cyanide liquors.—W. G. M.

*Annealing Metals, A Method or Process for.* L. Dong, London. Eng. Pat. 15,041, July 7, 1896.

THE metal is heated in a closed vessel, together with carbonaceous or other gas-producing material, such as oil or sawdust. The vessel is provided with a pipe for the escape or admission of gas, which can be opened or closed at pleasure.—J. H. C.

*Lead, Oxide of; Impt. in the Manufacture of, and Means used therefor.* A. Gutensohn, London. Eng. Pat. 16,271, July 22, 1896.

THREE pots are placed in cascade form, the upper two are connected near the bottom by a sloping pipe provided with a stopcock, and both are set above grates. The lower of the two has a circumferential gutter-like trough with an overflow into the third pot. The lead is melted and brought to a red heat in the uppermost pot, and is run down as required into the middle crucible, where it is subjected to the action of oxygen, or of air enriched with oxygen, which is either injected or blown upon the surface. A hood connected with a condensing plant is arranged over this crucible for the recovery of fumes. The oxide of lead formed, overflows into the gutter, and thence into the third pot at once, before it has time to exert any serious influence upon the material of the crucible.—W. G. M.

*Lead Sulphide, Ores of; Impts. in the Treatment of, preparatory to Smelting the same, and incidentally in obtaining Sulphurous Acid.* G. G. M. Hardingham, London. From T. Huntington and F. Heberlein, both of Pertusola, Italy. Eng. Pat. 3795, Feb. 12, 1897.

THE process is directed to the conversion of galena into lead oxide. The ore is mixed with sufficient lime or other alkaline earth to react with the sulphur present, and the mixture is heated to bright redness (about 700° C.) in a reverberatory or other furnace. It is then cooled to a dull red heat (about 500° C.) and transferred to a vessel in which it is exposed to a current of air, which may be preheated, and which is introduced by means of a blower. Under these conditions rapid oxidation takes place, sulphur dioxide is evolved (and may be utilised); much heat is generated, and the mixture fuses and gradually settles down to a mass of oxide of lead with the gangue stuff of the ore. The oxide of lead, containing calcium sulphate and gangue stuff, may then be smelted in a blast furnace. It is believed that the reactions taking place are as follows:—

- (1.) At 700° C. ....  $\text{CaO} + \text{O} = \text{CaO}_2$ .
- (2.) At 500° C. ....  $4\text{PbO}_2 + \text{PbS} = 4\text{PbO} + \text{PbSO}_4$ .
- (3.) At fusing point.  $\text{PbS} + \text{PbSO}_4 + \text{O}_2 = 2\text{PbO} + 2\text{SO}_2$ .

Ferrous or manganous oxide may be substituted for lime in the process.—W. G. M.

*Ores containing Zinc, Impts. in the Treatment of Solutions of, for the Recovery of Zinc as Oxide.* A. M. Clark, London. From E. A. Ashcroft, of Newcastle, New South Wales. Eng. Pat. 16,312, July 23, 1896.

ZINC sulphate is converted into a paste by stirring in zinc oxide, which is strongly heated so as to drive off sulphuric or sulphurous acid gases. In some cases the pasty mass is mixed with carbon before the heating.—J. H. C.

*Separation and Collection of Solid Matters [Dust of Ores, &c.] held in Suspension in Jerrifrom Fluids; Improved means applicable for use in the.* F. D. Cummer, Cleveland, U.S.A. Eng. Pat. 17,105, Aug. 1, 1896.

THIS invention relates to dust or settling chambers, and the process consists in blowing the air or gas through a pipe fitted with a deflecting screen into a brick chamber, where the greater part of the dust is said to be deposited, the lighter portions passing through openings into a superposed chamber provided with apparatus for spraying liquids or vapours, and with cooling appliances, after which the air or gas is allowed to escape.—O. H.

*Ores, Zinciferous Sulphide; An Improved Process for the Treatment of.* E. F. Turner, Adelaide, South Australia. Eng. Pat. 17,299, Aug. 5, 1896.

THE crushed ore is roasted, either alone or with carbon, in the presence of a current of superheated steam. In this

way the ore is oxidised and hydrogen sulphide is evolved when it is treated alone, or hydrogen sulphide and carbon monoxide are produced when carbon is added. The gas is collected in a gas-holder and used as a fuel, and the products of combustion are employed to treat the oxidised ore in towers, where the roasted ore, accompanied by water containing salt, is allowed to fall and so to meet an upward current of sulphur dioxide. In this way the zinc oxide is converted into sulphite, and may be afterwards leached out together with any copper that may be present. Lead oxide is partly converted into sulphite, and silver sulphide into chloride. The liquor from the zinc lixiviating vats is passed over copper to remove any silver, and then over zinc turnings to recover any copper and lead; it is then conveyed to towers, through which hydrogen sulphide (obtained as above described) is passed. Zinc sulphide and sulphur are thus precipitated. The gangue material in the vats is heated, whereby lead sulphide is converted into lead sulphate and sulphide, and these, being in contact with unchanged lead oxide, yield a soft lead. If the gangue material contain silver, it is mixed with zinc chloride, with or without metallic zinc, and heated to obtain the lead in the soft metallic state, whilst the chlorides of silver, gold, and other metals remain with the zinc chloride, and may be separated by lixiviation or otherwise.—W. G. M.

*Deoxidising Furnaces [Deoxidising Granular Oxide of Iron, &c.], Impts. in.* H. A. Jones, Brooklyn. Eng. Pat. 18,259, Aug. 18, 1896.

THE furnaces are made up of earthenware blocks fitted together, and secured by means of projecting flanges, thus forming a series of retorts, which are built into brickwork flues, the whole forming a zig-zag arrangement, which is heated by means of Bunsen burners or by liquid fuel. The retorts are supplied with hoppers, mixers, slides, cocks, and air pipes as may be required.

The claim is for the combination of these various components in the manner specified, for use as deoxidising furnaces for deoxidising granular oxide of iron and converting it into cast iron.—J. H. C.

*Aluminium, Impts. in Processes for Reducing.* F. A. Gooch, New Haven, U.S.A. Eng. Pat. 6151, March 9, 1897.

SODIUM fluoride or potassium fluoride is fused with alumina and a haloid compound of aluminium, and an electric current is passed through the fused mass, further quantities of the alumina or haloid compound being added from time to time.—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A).—ELECTRO-CHEMISTRY.

*Carbon, Electro-chemical Equivalent of.* A. Coehn. Zeits. f. Elektrochem. 1897, 3, 424—425.

CARBON anodes, in electrolytes which evolve oxygen at the positive pole, are rapidly destroyed. This is not simply a case of disaggregation—a chemical change takes place as well. The author has examined whether the electrolytic action can be regarded as coming within the scope of Faraday's law. He has endeavoured to determine the electro-chemical equivalent of carbon from the loss of weight of a carbon anode. The electrolyte consisted of equal volumes of sulphuric acid and water, and the electrolysis was carried on at a temperature such as to favour solution of the carbon and not disaggregation. The current was sent at the same time through two copper voltameters. The anodes were arc-lamp carbons 5 cm. long, 1 cm. in diameter, carefully boiled and dried at 200° beforehand. After electrolysis they persistently retained the brown-coloured solution, and required washing for several days. The most probable theoretical value of the electro-chemical equivalent of carbon would be  $12/4 = 3$ . The first determination quoted gave the value 3.5. This somewhat larger value was probably due to a partial disaggregation of the carbon. Preliminary experiments had shown that this occurred in

concentrated solutions without the electrolyte becoming in any way coloured; in more dilute solutions, however, the colour became a deeper and deeper brown. The new determinations were made with solutions containing from 10 to 500 volumes of water to 1 volume of sulphuric acid. The electrolysis lasted from 36 to 120 hours. The liquid was then filtered and the separated carbon particles washed and dried. Their weight was deducted from the loss of weight of the carbon anode. These determinations gave values varying from 2.7 to 3.0. Thus it appears that if we take the electro-chemical equivalent of hydrogen as  $H = 1$ , that of carbon is  $C = 3$ .—D. E. J.

RELATES to methods for obtaining high current densities with electrodes of platinum wire secured to supports of dielectric material.—J. C. R.

## (B).—ELECTRO-METALLURGY.

*Lead: Method of Treatment, rendering it more easily attacked by Chemicals in Preparation of White Lead, Accumulator Plates, &c.* J. Walter. Zeits. f. Elektrochem. 3, 1897, 449—450.

A GER. Pat. specification by the author, dated June 21, 1887, is quoted. The lead is alloyed with easily oxidisable metals, such as sodium, potassium, magnesium, aluminium, calcium, barium, strontium, manganese, or chromium. The metal alloyed with the lead is converted into oxide by exposure to air or removed by suitable reagents, leaving the lead in a pulverulent form well adapted for such processes as the "formation" of accumulator plates. The alloys with sodium and potassium are especially suitable. For the purposes under consideration the volume ratios, and not the mass ratios, are the determining factors in the composition and behaviour. As lead is ten times as heavy as sodium, 1 per cent. of the latter by weight corresponds to 10 per cent. by volume. The alloys are easily oxidisable, and can be cast on to any lugs or other conductors. The alloy removes any coating of oxide on the latter, and so makes a good electrical connection with it.—D. E. J.

## PATENTS.

*Ores containing Zinc, Impts. in the Treatment of.* A. M. and W. Clark, London. From E. A. Ashcroft, Melbourne, Victoria. Eng. Pat. 11,076, May 21, 1896.

THIS process was devised to enable zinc blende (alone or mixed with galena) to be so treated as to yield directly an electrolyte from which the zinc may be deposited electrolytically without formation of spongy deposits. This may be accomplished by having oxy salts of zinc in the solution from which the zinc is being separated. The ore is first roasted, to convert the zinc sulphide as completely as possible into oxide or sulphate. A portion of the roasted ore is then leached with aqueous ferric chloride or sulphate solution according to the process described in the amended specification of Eng. Pat. 13,850 of 1894, or is leached according to Eng. Pat. 13,534 of 1895 (this Journal, 1895, 658). Further portions of the roasted ore are finely crushed, mixed with finely divided carbon, and subjected to an even temperature of 650° C. (as nearly as possible) for about two hours. The zinc sulphate present thus becomes oxide ( $ZnSO_4 + C = ZnO + SO_2 + CO$ ). Portions of the resulting zinc oxide are then added to the

solution previously described, which should be heated in order to increase its capacity for dissolving the oxide. The resulting electrolyte is rendered available for continuous use by introducing, as required, further portions of the specially roasted product. If desired, portions of the ore may be treated directly without roasting, or roasting and acid treatment may be applied conjointly. When galena is present or the blende is impure, settling boxes should be placed in the path of the liquors to the electrolysis vats, to remove suspended matter. If the process is to be applied to the continuous deposition of zinc, the proportion of roasted ore to be leached will be small as compared with that converted into oxide; but if it be desired to prepare a quantity of the electrolyte the converse will be the case.

—W. G. M.

*Porous Metals by Electrolysis, An Improved Method for Obtaining.* L. Hoepfer, Berlin. Eng. Pat. 17,671, Aug. 10, 1896.

(1.) "A process for obtaining porous metals by electrolysis, mainly consisting in producing, alternately, spongy or porous, and dense metal precipitates, one operation serving to form the pores, and the next, to solidify or strengthen the walls of such pores."

Other claims relate to varying such conditions as the qualitative composition of the bath, the concentration, temperature, pressure on and motion of the electrolyte, and the density of the current; a solution of oxide of lead in caustic alkalis as electrolyte; the employment, as anodes, of impure metals with a view to their refinement; utilisation of the oxides forming at such anodes in obtaining by-products; and employment of porous metals obtained by the process in the preparation of plates for electrodes of secondary batteries.—J. C. R.

## XII.—FATS, OILS, AND SOAP.

*Castor Oil, Notes on.* H. Meyer. Zeits. angew. Chem. 1897, 297—295; Chem. Centr.-Blatt, 1897, [1], 1229.

THE author refers to the work of Juillard (Bull. Soc. Chim. 13 [3], 238), and states that the formation of complex polyricinoleic acids, resembling esters, takes place gradually at the ordinary temperature, without the use of condensing agents. A preparation of pure ricinoleic acid, 8 years old, showed on titration 30—40 per cent. less acidity than the freshly-prepared acid. These poly-acids are completely saponified, i.e., reconverted into ricinoleic acid, in 24 hours, by warm alcoholic potash.

On heating ricinoleic acid and glycerol to 280°—300° C., passing in  $CO_2$ , and then washing with water to separate the excess of glycerol, the nearly chemically pure triglyceride of ricinoleic acid was obtained, in the form of a nearly colourless, neutral, active purgative oil, similar to natural castor oil. The oil was soluble in 96 per cent. alcohol and in methyl alcohol, had a specific gravity of 0.959—0.984 and  $[\alpha]_D + 5.16^\circ$ . It does not form, like natural castor oil, a solid ricinelaidin on treating with nitrous acid. On preserving for a year, the molecule of ricinoleic acid triglyceride becomes doubled or tripled, the specific gravity being increased (0.988—1.009), and the iodine number reduced (from 71—84 to 44—57). The author states that the oil obtained by Juillard, said to be a mixture of tri- and diricinolein, must have been the nearly pure diglyceride of ricinoleic acid.—A. S.

*Chinese Oil Tree.* U.S. Cons. Reps., Aug. 1897, 477—483. (See this Journal, 1897, 195.)

THE wood-oil tree, or *Aleurites Cordata*, belongs to a family very common in China, known as the "tung." The wood-oil tree is the ying tzu tung, so called from the shape of its fruit—ying means a jar. It is also known as the yiu tung or oil tung. It is found chiefly in Hunan, Hupeh, and Szechuen. The seeds are large and poisonous, and it is from them that the oil is expressed. The fruit is gathered in August and September. Hankow is the chief place of export. In the first three quarters of 1896, 188,556 piculs (1 picul = 133½ lb.) of this oil were exported.

The oil is expressed from the seeds as follows:—

The nuts are gathered and dried, put in a shallow iron basin about 2 feet in diameter, and stirred about over a good fire until parched; they are then ground to a fine powder, the oil dripping out into a receptacle. When allowed to settle, and strained through coarse grass cloth, the oil is ready for the market. It is sent down in plaited baskets, lined with putty and varnished paper, with large wide mouths. It is usually of a light colour, somewhat resembling linseed oil, and emits a nauseous odour.

This oil is largely used for painting and calking. Mixed with sifted lime it makes excellent glaziers' putty. After the oil is removed, the nut is calcined or burnt, and produces a very valuable soot, from which Chinese ink is made (or India ink, so called). Cement, or chunam, for seams of boats, is made from this oil. It costs about 90 cash (6 cents) per pint in the village where produced, and is sold at double that price in Hankow.

The oil is extremely poisonous when fresh. A simple native remedy (more effective, indeed, than any foreign one) is to boil a quantity of pine shavings in water and bathe the poisoned part repeatedly. It gives immediate relief, and rapidly cures. The curious aspects of wood-oil poisoning are worthy of special study.

The best wood-oil comes to Hankow from Shin-chau Fu, in Hunan. The oil is given as a remedy in insanity and in cases of metallic poisoning. It is emetic, acro-narcotic, and drastic, proving destructive to rats in a very short time. It is applied as a stimulant to carbuncles, ulcers, burns, swellings, and bruises, and is a constant ingredient in native plasters. It was forbidden to be exported during the Taiping rebellion, as it is a necessary article for shipyards.

*Chinese Insect White Wax.* U.S. Cons. Reps., Aug. 1897, 484—490.

Since the introduction of kerosine oil into China, and its almost universal use in the remotest provinces of the Empire, the demand for white wax has declined considerably, and the supply has decreased in a corresponding ratio. The value, like the demand, has also declined. Not many years ago it was quoted at double the prices realized at present.

Various uses are ascribed to this wax, but in western China its sole use is for coating the exteriors of animal and vegetable tallow candles and for giving a greater consistency to these tallows before they are manufactured into candles. Insect white wax melts at 160° F., whereas animal tallow melts at about 95° F. Vegetable and animal tallow candles are therefore dipped into melted white wax; a coating is given to them, and prevents them guttering when lighted. It is also said to be used in other parts of China as a sizing for paper and cotton goods, for imparting a gloss to silk, and as a furniture polish. Chemists are likewise declared to utilise it for coating their pills. In the Fukien and Chékiang provinces it is employed to impart a polish to stoneware, or soapstone, ornaments after the carving is completed.

### XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS, &c.

*Driers, Solid or Liquid.* H. Amsel. Zeits. angew. Chem. 1897, 303 and 341.

THE opening part of this article consists chiefly of a discussion of the results and opinions recorded by Weger (this Journal, 1896, 728). Weger appears to doubt whether soluble resin driers are ever adulterated with free resin (colophony); such is the case, however, and although perhaps it is not a matter of great moment if 10 or 20 per cent. of uncombined resin exist in a substance which is added only in amounts of 1.5 to 2.0 per cent. of varnish, yet when the drier itself has to be examined, if part of the resin be in a free state, the sample cannot be returned as a pure resinate.

Combining together some of the suggestions made by Weger with the processes he has already published, the present author puts forward a scheme for the analysis of the solid soluble driers, which enables their constitution and the presence of free basic or acid matter to be recognised, and which it is believed will throw some light on their actual industrial value. He determines (1) the solubility in chloroform, (2) in alcohol, (3) combined and free mineral matter, (4) acid number, (5) saponification number, (6) reaction with ammonia, and (7) moisture. (2) is returned not only as a percentage, but also as the amount taken up by 100 parts of alcohol in the cold. The combined mineral matter is estimated by deducting the quantity insoluble in chloroform from the total inorganic substances; it is not advisable to obtain this figure simply by weighing the ash of the soluble portion; but, after a preliminary qualitative examination, each ingredient should be separately determined in the ordinary way. The titration for (1) is carried out both with the material partly dissolved in alcohol, and also completely dissolved in chloroform, the latter process naturally giving higher results. It should be noticed that considerable insight into the nature of the acids present in the sample can be gained by observing its behaviour during titration; for in the case of linoleates the phenolphthalein is temporarily reddened before shaking almost by the first drops of alkali, while with resinates the colour only appears shortly before actual neutrality is reached. (6) depends on the fact that free resin is saponified by shaking in the cold with 1 per cent. ammonia; so that if a pure resinate be treated in this manner and the liquid filtered, it should pass through the paper readily, and the filtrate should only give a slight cloudiness on dilution or acidification. Stronger solutions of ammonia are useless, and even the different results shown in the table may possibly be due solely to variations in the quality of the original resin. The moisture (7) is estimated at 90° or 95° C. Illustrative tables are given.—F. H. L.

*Lead, Method of Treatment rendering it more easily Attacked by Chemicals in Preparation of White Lead, Accumulator Plates, &c.* J. Walter. Zeits. f. Elektrochem., 3, 1897, 449.

See under XI. B., page 684.

#### PATENTS.

*Paint [Black, for Ships' Bottoms], and in the Method of Producing and Applying same, Impts. in.* H. W. Aird and C. E. Felch, Montreal. Eng. Pat. 17,078, Aug. 1, 1896.

THE vehicle consists of 30 galls. of linseed oil, 60 galls. of turpentine, 20 lb. of litharge, 5 lb. of manganese oxide,

and 100 of kauri-copal. 100 lb. of this are ground with 110 of Canadian graphite, and the whole thinned with 10 galls. of turpentine and 1 gall. of oil. Canadian graphite has, for this purpose, the advantage of containing some 50 per cent. of a "disintegrating substance" resembling felspar; but if the Ceylon product is employed in the manufacture of the paint, a certain quantity of felspar should be added. According to the purpose for which the composition is to be used, it may be diluted with black japan and (or) turpentine—the latter giving the smoothest but least durable coating. It is specially adapted for ships' bottoms. —F. H. L.

*Branding Sheep. Fabrics such as Wool Bales and the like. An Improved Composition for; and Applicable as a Damp-resisting Paint.* A. L. Potter, St. Kilda, Victoria. Eng. Pat. 11,013, May 3, 1897.

THE object of this invention is to provide a material capable of withstanding rain and heat, which can yet be removed by treatment with soda and water, and at the same time will not injure the wool or surface to which it is applied. 3 lb. of glue,  $\frac{1}{2}$  to 1 oz. of potassium bichromate, 3 lb. of lamp black or any other pigment, and  $\frac{1}{2}$  pint of turpentine are boiled in 1 gall. of water, some Spanish clay being added if desired to increase the tenacity. If necessary the mixture may be thinned with hot water.—F. H. L.

#### (C).—INDIA-RUBBER, &c.

*India-Rubber Industry, Impts. in the.* A. Henriques. Chem. Zeit. 21, 415.

WITHIN the last few years nothing of any considerable interest has appeared either regarding the chemistry of india-rubber or concerning the general manufacturing methods employed in the india-rubber industry. But our botanical and statistical information as regards india-rubber plants and commercial brands of crude india-rubber has been not inconsiderably added to. Manoel V. Continho describes a new smoking process for Pará rubber, in which the smoking is carried out in a horizontally revolving cylinder, 5 ft. 2 in. in circumference, into which is passed the smoke of burning Urucary nuts (*Athalea excelsa*) or Inajá nuts (*Marimiana regia*). East Indian rubber exports keep decreasing in quantity owing to the reckless exploitation of the ficus forests. Little is heard concerning the india-rubber plantations started at Ceylon, Madras, Trinidad, Togo, and Cameroon, but the export of india-rubber from all parts of Africa is rapidly expanding. According to K. Schumann, the African rubbers are obtained from 14 species of the genus *Landolphia*. A. Dewèvre in this respect enumerates 21 species of which *landolphia kirkii*, *madagascariensis*, *owariensis*, *Petersiana*, *lucida*, *Senegalensis*, and *tomentosa* produce the best brands, whereas the very common *L. comorensis* var. *florida*, which formerly was considered the most important of African rubber-bearing plants, is now stated to yield a useless, resinous product only. Of African rubber trees, only *Ficus Vogeli* and *F. Kotsii* were known, but since 1894 ever increasing exports from Lagos took place of an india-rubber obtained from a tree called Ire (Ere) by the natives, and which is botanically described as *Kickxia Africana* Benth. The exports from Lagos in 1895 amounted to 5,069,504 lb., to the value of 269,892*l*. It is stated that the same tree also occurs on the Gold Coast, Togo, and Cameroon. It remains, however, to be seen whether this boom does not result in a speedy annihilation of the rubber trees. The output of india-rubber in the Congo basin has also considerably increased. Concerning the chemistry of india-rubber, C. O. Weber

investigated the action thereon of bromide and iodide of sulphur. Henriques confirms his former statement that pure india-rubber, on being heated, protected from light, absorbs traces only of oxygen, whereas, after vulcanisation, the same samples absorb oxygen very freely, especially after they have been deprived of their free sulphur. J. Altschul has thrown some light upon the nature of the india-rubber substitutes, by showing that the amount of chloride of sulphur required for the conversion of an unsaturated oil into solid substitute is greatly reduced by first treating the oil with sulphur at from 140° to 160° C. The patent literature of the india-rubber industry has considerably increased. F. G. Kleinstenber (Ger. Pat. 84,065, 87,673) prepares a product, commercially known as ambroin, by mixing solutions of copal with fibrous materials, and exposing these mixtures to high pressures. A process for vulcanising with electricity has been patented by Bergeon (Fr. Pat. 243,377), and C. Dreyfuss obtained a patent (Ger. Pat. 85,236) for vulcanising with a solution of chloride of sulphur in benzene.—C. O. W.

#### PATENT.

*Impreguating of Materials with India-Rubber, Gutta-Pereha, and the like; Impts. in and relating to the.* W. J. A. Donald, Glasgow. Eng. Pat. 18,517, Aug. 21, 1896.

THE fabric—leather, cotton, canvas, &c.—is dried, then passed through a warm bath of naphtha or carbon bisulphide, dried again, and finally treated with a solution of india-rubber maintained at a temperature of 100° or 110° F. The finished material is specially adapted for the construction of pneumatic tyres.—F. H. L.

#### XIV.—TANNING, LEATHER, GLUE, SIZE.

*Leather, The Testing of.* W. Eitner. Der Gerber, 23, 53.

THE test, depending on the observation that leather does or does not become transparent in water, is valueless. Neither well nor badly tanned leather, nor even raw hide, becomes transparent in water. The swelling or gelatinising action of strong acetic acid upon leather is rather important, and is, for an acid of given concentration, the more pronounced the smaller the quantity of tannic acid contained in the leather. A leather which is not affected by acetic acid of a certain concentration, will however begin to swell if subjected to the action of a more concentrated acid. If the concentration of the acetic acid exceed a certain limit, it will swell or even gelatinise even the strongest tanned leather. Unevenly tanned leather is also unevenly acted upon by acetic acid, so that the observation of the action of this acid upon a section of the leather affords valuable information concerning the thoroughness or penetration of the tan. Thus, well tanned leather belting on immersion in acetic acid of 20 per cent. strength should not show swelling of the fibre to such a degree as to cause a glassy and pellucid appearance, since the tensile strength of leather decreases as the degree of penetration of the tan increases. On the other hand, sole leather allows a much higher degree of penetration, and will therefore withstand the action of an acid of correspondingly higher penetration. The use of this test as a criterion of the quality of a leather requires therefore considerable discrimination.

Another test according to which the leather after half an hour's boiling in distilled water should not, by the conversion of the leather into glue, render the water turbid, is very misleading. The presence in the leather of such an excess of tannin as would be required to satisfy this test would be fatal to the quality of many kinds of leather, and it will be found that especially the various kinds of tough leather would not stand this test. No better is the test in which the leather is boiled in a solution of alum, which, it is said, ought to remain clear.—C. O. W.

*Suède or Glove Kid, The Tanning of.* Der Gerber, 23, 41.

THE most important item in the production of suède and glove kid consists in the selection of the skins. These should be very firm, of a fine texture, and they should also be of the requisite dimensions. The next important point

is to conduct the tanning in such a manner as to preserve as much as possible the natural structure of the skins, and to avoid swelling. First class qualities of this leather can only be obtained from American young goat skins. The liming of the skins is carried out in very weak milk of lime, with an addition of sodium sulphide. The latter in French tanneries is often used by itself, or in conjunction with only very little lime. It renders the skins smoother, softer, more elastic and durable than the ordinary liming process, and, besides tending towards economy in the quantity of eggs required, yields skins which are not only very easily dyed but also assume very brilliant shades. In the sodium sulphide treatment the skins, though swelling, never become spongy. They at once re-assume their former thinness and toughness on immersion in water, whereas the lime treatment by itself always results in the texture of the skins becoming somewhat loose and rough. The time the skins require in this treatment varies from 7 or 8 to 10 or 12 days according to whether the depilation of the skins is carried out by hand or by machine, the latter of course being much the cheaper. After depilation the skins are sorted, those suitable for suede or glove kid are treated accordingly, the inferior skins are trimmed, dugged, cleared in acid bran water and pressed.—C. O. W.

*Shoe Leather, The Tanning of.* W. Eitner. Der Gerber, 23, 42.

THE fault most commonly committed in the tanning of shoe leather consists in working the hide too long in too weak liquors. The haired and fleshed hides are for two days treated in hemlock liquor and are taken successively through four liquors made up with two-thirds of hemlock and one-third of oak bark. In each of these liquors the hides remain for four days. They are then passed into three further successive liquors made up with equal parts of hemlock and quebracho (not the extract), remaining a week in each fresh liquor.—C. O. W.

*Leather Dressing, Employment of Urine and Dog Excrement for Glove Leather.* E. D'Huart. Bull. Assoc. Belge des Chimistes, 11, [1], 21—39.

As a result of numerous experiments in the works and the laboratory, it appears that the effect of the canine excrement employed for dressing glove leather is due to the action of a microbe present in large numbers in the excrement and acting upon the amorphous organic matter of the cutaneous tissue and on the residue of the epidermis, which it destroys, the fibrous bundles being at first protected but becoming subsequently attacked if the exposure be prolonged.

The author considers that this explains why attempts made to replace this agent by various chemicals have proved unsatisfactory, the true cause of the action having been hitherto ignored, since the only rational substitute would be a bouillon containing the microbe in question, and not merely a mixture of ammonia, ammonium carbonate, and sodium phosphate. The same effect can, it is true, be produced by a complex mechanical treatment of beating, steeping, &c., but this is a much more expensive process than microbial action.—C. S.

## XV.—MANURES, Etc.

*Nitratin, Experiments with.* Standard Agricultural Reps., Aug. 10, 1897.

DIRECTOR Dickson and Professor Malpeaux, of the Berthouval (Pas-de-Calais) School of Practical Agriculture, describe in the *Journal d'Agriculture Pratique* some experiments which they have carried out with nitratin, Prof. Nobbe's preparation of nitrogenous bacteria. They first tried the preparation on clover grown in pots of sterile sand, to which some superphosphate of lime, sulphate of potash, and powdered lime had been added, cutting the produce in the flowering stage. From a pot to which no nitratin was applied they obtained 109 grms. of green clover; from a corresponding pot without nitratin, but with some nitrogenous manure, the produce was 132 grms.; from a third

pot for which the nitratin was mixed with the seed they cut 159 grms.; and from a fourth, for which the nitratin was mixed with the soil, the crop was 168 grms. There were some duplicate pots from which the produce was almost exactly as given above. Lupins grown under like conditions gave 203 grms. in one case, and 205 in another without nitratin, and 250 with it. A trial with clover in the open ground showed a gain from the use of nitratin, but a less striking one than in the pot experiments. In the case of vetches grown on a plot of ground after wheat without nitratin the produce was 219 kilos., while, with nitratin mixed with the seed grain it was 232 kilos., and where the preparation was mixed in the soil it was 238 kilos. In a trial with white lupins no increase was obtained by mixing nitratin with the seed, but a substantial gain was derived from inoculating the soil with it. (This Journal, 1896, 767.)

*Guano Deposit, The Utah.* Eng. and Mining J. 1897, 63, 602.

THE deposits vary in thickness from 1 to 20 feet, and a recent estimate of the material in sight, after a very thorough examination, gives the total at over 1,000,000 tons. Analyses show that the Utah guano has about half the percentage of the soluble ingredients contained in the standard high grade Peruvian guano.—A. S.

*Aluminium Phosphate from the Island of Grand-Connétable, Manurial Experiments with.* A. Andouard. Ann. Agron. 1896, 22, 247.

EXPERIMENTS were made in which garlic, wheat, rape, beans, and black radish were grown in poor sandy soil to which potash, lime, magnesia, and nitrogen were added, besides 1 per cent. of phosphoric acid in the form of aluminium phosphate, crude bone-meal, basic slag, and superphosphate respectively. In most cases there was clearly assimilation of phosphoric acid applied as aluminium salt. In the case of beans, however, the yield of dry produce under the influence of aluminium was very low, as compared with bone-meal and superphosphate. Similar experiments in which garlic, rape, and radish were grown in garden soil, without manure, and with aluminium phosphate gave very irregular results.

The effect of aluminium phosphate on three kinds of wheat, growing in the field of the Experiment Station of the Lower Loire, was compared with basic slag and with Ardenne phosphoric meal. All three manures gave about the same yields of wheat.—N. H. J. M.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Sugar Canes, Mode of Sampling and Method of Analysis of.* Report on the Agric. Work in the Botan. Gardens, British Guiana, for the Years 1893-4-5; 9-10.

A REPRESENTATIVE sample, as far as can be judged by the eye, is taken, consisting of at least six ordinary canes, or from three to six seedling canes, according to the number of fully developed canes in the stool. It is stated that by this method of sampling, the errors are insignificant compared with those of cultivation caused by unfavourable conditions of soil and seasons. The large samples varying in weight from 15 to 30 lb. are sampled down in the following manner the same morning as they are cut down. The canes are sorted into pairs according to their physical characteristics. If of medium length, each cane is divided into four equal parts, and the top and third portions of one cane, and the second and butt portions of the other are reserved for the sample. The portions of the three composite canes thus obtained are split in half, one-half of each portion being taken to form the sample for analysis, and the remaining halves forming, if necessary, a reserve sample. Representative samples of 4 to 8 lb. in weight are thus obtained. When very large canes are being examined, they are first grouped in threes, each cane is divided into six parts, and the top and fourth portions of the first cane, the second and fifth portions of the second, and the third and butt portions of the third are taken to form a composite sample cane. The two composite canes thus obtained are further divided as already described.

The longitudinally divided half-canes are passed through the mill at first singly, then the expressed residues or megass from two pieces are placed together and passed through, this being repeated three times. An extraction is thus obtained approximating to that yielded by double crushing, but the juice obtained contains somewhat less of the sap constituents of the cane than that obtained on the large scale, and is consequently richer in sucrose, of a higher density, of a higher quotient of purity and of a lower quotient of non-sugars. The specific gravity of the juice, after straining from the coarser suspended impurities, is taken by a Westphal balance, arranged to show the density as at 84° F., which, as the coefficients of expansion of water and cane juice are practically the same, is identical with the density at 60° F. 50 c.c. of the juice are pipetted off into a 100 c.c. flask, clarified with a little sub-acetate of lead, the excess of lead precipitated by sodium phosphate, then the whole made up to 100 c.c., filtered and polarised in the usual manner. The glucose is determined in the liquid used for polarisation by means of accurately standardised Favy's ammoniacal copper solution. The ash is determined by evaporating 5 c.c. of the original juice to dryness and burning at a barely visible red heat in a muffle furnace. The total solids, and thus indirectly, the non-sugars, are usually deduced from the specific gravity, but on estimating them by direct evaporation, it was found that the results obtained, in the case of the juice of the Bourbon cane, were 0.2 to 0.3 per cent. lower than those calculated from the density.—A. S.

*Sugar Cane, Presence of Levulose in Ripe.* H. C. Prinsen Geerligs. Bull. Assoc. Chim. 1897, 14, 1080—1086.

In reply to the criticism of Pellet (this Journal, 1897, 250), the author shows that precipitation of levulose could not have occurred in his experiments on the juice of young and ripe canes, as he used only a few drops of acetate of lead slightly basic, and the filtered liquor was always left acid to litmus. He contends that the reducing sugars should not be studied in the molasses but in fresh juice, as they undergo great changes during the course of manufacture.

The following experiments made at the suggestion of Pellet show that in an acid medium, levulose is not precipitated by addition of basic acetate of lead; thus, in the author's experiments, all the sugars present passed into the filtrate, which was polarised, and in which the reducing sugars were estimated. Pellet had also found that levulose which was not precipitated by basic lead acetate in a simply aqueous solution, was immediately precipitated in part when a lead precipitate caused by salts, was formed in the solution. These results were fully confirmed by the author. The following solutions were made up to 100 c.c. and filtered before being examined:—

—	Sugar.	Dextrose.	Levulose.	Common Salt.
	Grms.	Grm.		
(1)	15	..	..	1
(2)	15	..	..	1
(3)	15	0.5	0.5	1
(4)	15	0.5	0.5	1
(5)	..	0.5	0.5	1
(6)	..	0.5	0.5	..

—	Basic Acetate of Lead.	Polarisation.	Reducing Sugars found.
	c.c.		
(1)	..	56.9	..
(2)	10	57.0	..
(3)	..	56.1	1.02
(4)	10	56.5	0.82
(5)	..	0.8	1.02
(6)	10	0.7	0.53

It is thus seen that sub-acetate of lead has increased the polarisation of (2) by 0.1 degree on account of the volume of the precipitate, but has considerably increased the polarisation in the cases of (3) and (4) and of (5) and (6), in

consequence of the precipitation of levulose, and has diminished the quantity of reducing sugars for the same reason. To prove that the precipitate contained levulose, the precipitates of (4) and (6) were washed with water and dissolved in acidulated water. The solution was levo-rotatory and contained 0.18 gm. of reducing sugars. Neutral acetate, however, changed neither the polarisation nor the glucose found, so that by employing the reagent neutral or using the sub-acetate in so small a dose that the cane juice remains acid, there is no precipitation of levulose.

The author is completely in accord with Pellet that the quantity of dextrose and levulose in cane molasses is about the same as in invert sugar, but he is opposed to the conclusion that it follows that these two bodies are therefore found in the same proportion in ripe cane. This would be absolutely true if the reducing sugars underwent no change during the manufacture. Unfortunately dextrose and levulose do not remain intact during the heatings and re-heatings with lime and salts which they undergo in the factory. Alberda van Ekesteyn and Lobry de Bruyn have shown (this Journal, 1896, 210) that on treating dextrose with small quantities of base it is partially transformed into levulose and mannose. But it is not necessary to employ alkali in excess. The author made a solution containing 10 per cent. of dextrose and sodium acetate equivalent to 2.5 per cent. of Na<sub>2</sub>O, and a similar solution containing 2.5 per cent. of K<sub>2</sub>O. These two solutions were heated in a Koeh's sterilisation cylinder so as to remain at 100° C. without evaporation. After one, two, three, and four hours, portions were withdrawn and tested. The polarisations gradually diminished from 27.3 and 26.9 to 12.6 and 9.8 respectively, whilst the reducing sugars remained practically the same. The quantity of reducing sugars is therefore not affected by this transformation, but merely the quality. A solution of dextrose, after heating with sodium acetate until the rotation was almost zero, was evaporated and mixed with phenylhydrazine acetate and alcohol: a yellow precipitate was gradually formed, and was recognised as the phenylhydrazone of mannose. The remaining solution extracted with ethyl acetate gave a levo-rotatory sugar with all the characters of levulose. The preponderance of dextrose in ripe cane is moreover not astonishing if one considers the formation and fixation of sugars in the cane as worked out by Went, whose microscopical researches give results in perfect agreement with the chemical analyses of the author.—L. J. de W.

*Raffinose in Cane Molasses.* H. Pellet. Bull. Assoc. Chim. 1897, 14, 1086—1089.

WHEN raffinose is present in only small quantity, the results of the analysis are not sufficiently affected to be considered abnormal; it is necessary for the percentage of raffinose, as determined by the inversion method, to reach 2 to 3 per cent., or that the residue after fermentation should polarise strongly to the right for the attention of the chemist to be called to the presence of this sugar. It was thus that Pellet and Barbet were led to suspect the presence of raffinose in a sample of cane molasses from Louisiana; and subsequently they adduced evidence that it contained 2 to 3 per cent. on the weight of the molasses. Other samples, notably in Egypt, did not show sufficient to appreciably affect the results, even when examined after the reducing sugars had been removed by fermentation.—L. J. de W.

*The Ranson Process.* [Decolorising and Purifying Sugar, Syrups, &c.] A. Vivien. Bull. Assoc. Chim. 1897, 14, 1073—1077.

THERE are two methods of operation in the Ranson process. That preferred in the refinery is to oxidise organic matters by adding oxygenated water, and then to add a substance having a great affinity for oxygen, such as a sulphite, hydro-sulphite, or the corresponding acid. The second method is the inverse of this. It commences by treatment with hydro-sulphurous acid in the nascent state, and terminates in the use of oxygenated water, to destroy the affinity of hydrosulphurous acid and oxidise the sulphites formed, and any organic matter capable of being destroyed by oxidation. Oxygenated water acts on organic matters through the nascent oxygen as well as by the molecule of water, both in the nascent state, formed when it decomposes. Any

excess would act on sugar and form glucose, lactic acid, &c. By operating methodically no trace of the reagents employed remains in the liquors treated. The zinc powder used in the preparation of the hydrosulphurous acid also combines, in the form of oxide, with certain organic matters and precipitates them. The combined result of the reactions is purification and decolorisation.

In applying the process in the factory, the syrups and drainings which are to form the first runnings massecuite are treated in the ordinary sulphiting vats with sulphurous acid to neutrality and then filtered. The greater part of the calcium sulphite is thus eliminated, producing an increase of saline quotient and of purity.

The syrups are then passed, at a temperature of 45° C. to sulphiting vats provided with agitators and "Ranson" oxygenated water added in quantity to transform the soluble sulphites into sulphates. The syrups are then sulphited a second time, so as to leave an acidity expressed as sulphurous acid of 0.5 to 5 gramm. per litre, according to the nature of the syrup, then 10 to 50 gramm. of zinc powder is added per hectolitre of syrup and vigorously agitated for 15 to 20 minutes. Hydrosulphurous acid is formed, which is a very energetic reducing agent. In its nascent state it destroys 85 to 95 per cent. of the colouring matter, precipitates some nitrogenous matters and considerably diminishes the viscosity of the syrups.

After heating to 75° C., if there is any fear for the nature of the syrup, it is neutralised by baryta, or better, by barium sucrate, but with sound beets it may be left slightly acid and the cost of baryta reduced.

The massecuite obtained is pale, fluid, easy to machine, and gives an extra sugar which keeps perfectly in store.

When it is boiled acid, the drainage syrups are made slightly alkaline, sulphited and treated as before. The first runnings massecuites are very fine and slightly alkaline, the acidity of the syrups due to organic acids and sulphurous acid disappears, during the boiling, in the condense waters and gives a further purification. No uncrystallisable sugar is formed when working under the above conditions. The plant required is very simple and already exists in the greater number of the factories employing the ordinary sulphiting. For the treatment of first runnings syrups it is preferable, though not indispensable to have recourse to double filtration; the sulphiting vats where zinc powder is added should be furnished with refrigerators and stirrers. The cost of materials is about 0.2 franc per 100 kilos. of sugar. The advantages are:—Increased yield, about 5 kilos., and diminution of molasses, about 10 kilos. per 1,000 kilos. of beetroots, with a gain of 4.867 francs.—L. J. de W.

#### *The Ranson Process, Application of, in the Sugar Refinery.* Bull. Assoc. Chim. 1897, 14, 1077—1080.

VERY pure sugar solutions are obtained by the Ranson process (see previous abstract), perfectly decolorised and purified; the massecuite is very white, and is subsequently converted, by special mechanical means, forming part of the process, into fine slabs of refined sugar for breaking into lump, which can be delivered for consumption within 48 hours.

When the oxidising treatment is employed, that is when oxygenated water is used first, the syrups (clairce for boiling or fine clairce) are rendered alkaline with baryta, or failing that, with carbonate of soda, Ranson oxygenated water added and mixed for about two hours at 40 to 50° C. The decolorisation and purification are effected during mixing. An excess of oxygen is used to obtain as complete a decolorisation as possible, and this excess is removed immediately afterwards, or the syrups would be attacked and subsequently recoloured, forming fatty acids, butyric, ulmic, propionic, waxy matters, &c. The excess of oxygen is removed by hydrosulphurous acid ( $\text{H}_2\text{SO}_2$ ), which at the same time decolorises the syrups and diminishes the viscosity. The hyposulphurous acid is added as barium, aluminium, &c., salt, or in the free state, and in the latter case it is produced in the liquid itself in the nascent condition. A slight excess is used in order to utilise its special action in completing that of the oxygenated water. By operating thus, the colouring matters rich in oxygen are destroyed by reduction, whilst

those poor in oxygen have already been destroyed by oxidation. At the same time there is a purification by precipitation of organic matters in the form of organic salts of baryta and of zinc and diminution of viscosity. The excess of hydrosulphurous acid is removed by a fresh addition of oxygenated water exactly determined by titration with iodine and starch. Finally it is heated to from 75 to 80° C., and filtered mechanically.

The process may also be carried out commencing with the reducing treatment with hydrosulphurous acid.

The purity and saline quotient are raised and  $\frac{1}{3}$ ths of the colour removed, as shown by the following analyses:—

Per Hectolitre.	Fine Clairce.		Clairce for Boiling.	
	Initial.	After the Ranson Treatment.	Initial.	After Treatment.
Sugar.....	66.050	66.050	54.000	54.000
Glucose.....	0.005	0.005	0.150	0.150
Ash.....	0.164	0.160	0.235	0.220
Organic matter.....	0.222	0.158	1.820	1.380
Water.....	33.169	33.537	43.795	44.250
	100.000	100.000	100.000	100.000
Purity.....	96.28	96.38	96.07	96.87
Saline quotient.....	402.80	412.81	229.78	245.45
Decolorisation.....	Type	78.00	Type	75.00
Alkalinity.....	Trace	Trace	Trace	Trace

The plant necessary for the treatment of syrup in the refinery consists of tanks furnished with stirrers, and of mechanical filters; the treatment is simple, readily acquired and easy to control. The cost of the process is 0.15 franc per 100 kilos. of sugar melted, or 0.20 franc if sugar composed of  $\frac{1}{3}$ ds of No. 3 and  $\frac{1}{3}$ rd brown sugar is used, the drainage syrups being returned, so as to have a melt of 96 per cent. minimum.—L. J. de W.

#### *Diffusion and Seum Washing, Limits of Loss in.* H. Pellet. Bull. Assoc. Chim. 1897, 14, 1089—1093.

THE question of the loss of sugar in exhausted beetroot pulp has been studied by Karlson (Bull. Assoc. Chim., March 1897), who concludes that as the purity of molasses may be reckoned at about 60, the weak juices of the last diffusers should not be worked if they have a purity equal or inferior to this, and consequently the loss of sugar in the pulp will be variable, and may be high. For example, if the weak juice of the last diffuser, in which the exhausted pulp contains 0.30, has a purity of 45, this juice will produce only molasses, and will, besides, take up sugar so as to come out in the molasses of 60° of purity. If the last diffuser contain a weak juice of 60° of purity, and the pulp 0.60 per cent. of sugar, it should be stopped at this point, otherwise the production of molasses will be increased, this conclusion being based on the fact universally known and acknowledged that the further the diffusion is pushed the more impure is the product obtained.

Although this is true in a general way, if the pulp be exhausted by increasing the volume of juice drawn off, but if, by special arrangements which have been put into practice, the pulp can be exhausted with a less volume of liquid, the total purity of the product extracted may be higher, and less sugar left in the exhausted pulp.

The purity of the weak juices is falsified, however, in various ways. The water used has a great influence. 3 grms. of sugar dissolved in a litre of ordinary water showed a purity of only 66 on the ordinary instruments, without having been in contact with the pulp. When the impurities brought by the water used for diffusion are taken into account, the impurities coming from pulp more or less exhausted will be found to vary very little, and the last juice extracted as pure as that extracted first.

In concentrating the thin juice, it is best to evaporate in a copper dish to 114° C., when, if the juice has been well purified, the colour is the same as the juice from which it

was produced. In this way several litres may be evaporated in a few hours, care being taken that it does not burn at the sides, as it does in porcelain vessels.

The same considerations apply in washing the semms. No more impurity is obtained, when the washing is complete, with a small quantity of water than with a larger quantity. The impurity is mostly lime, from particles incompletely carbonated, as may be seen from the increase of alkalinity.

—L. J. de W.

*Beetroot, the Different Forms of Nitrogen in the, and their Influence on the Relative Proportions of Sugar and Glucose.* E. Urbain. Bull. Assoc. Chim. 1897, **14**, 1095—1098.

It is constantly remarked that on beginning the manufacture of sugar the beetroot contains only traces of reducing sugars, but as manufacture proceeds the quantity increases, particularly for beetroots in silos. With the increase of reducing sugars, the nitrogen anides and ammonium salts also increase, at the cost of albuminoids and nitrates, the total nitrogen being sensibly constant. This may well explain the great difficulties presented by purification towards the end of the season, for if the albuminoids are almost entirely precipitated by lime, it would not be the same with the soluble nitrogen compounds. There is evidently disengagement of ammonia during carbonation, but not in sufficient quantity to compensate for the albuminoids which have disappeared. The presence of a larger quantity of nitrogen as ammonium salts may also explain the diminution of alkalinity during evaporation, for there is here a veritable displacement of ammonia, so well known that it is unnecessary to insist upon it.—L. J. de W.

*Wheat, The Insoluble Carbohydrates of.* H. C. Sherman. J. Amer. Chem. Soc. 1897, **19**, 291—310.

The author divides his communication into three parts—descriptive, analytical, and physiological. In the first part he concludes from his experimental evidence, that the hemicellulose of wheat consists of pentose anhydrides or true pentosans, since, on inversion with dilute sulphuric acid, pentoses only are obtained. The action of ferric chloride and potassium ferricyanide on wheat fibre showed that, like the typical lignocellulose (jute), the amount of cyanide fixed upon the fibre varied roughly with the amount exposed to the action. This reaction is interesting as

showing the similarity of the lignocellulose molecule in these tissues. Pursuing Cross and Bevan's directions ("Cellulose," p. 135) the author obtained with wheat fibre a lignone chloride, which, on analysis, gave numbers agreeing with the formula  $C_{19}H_{15}Cl_4O_9$ . The fact that this compound can be obtained from such widely different tissues as that of the coat of the wheat grain and jute fibre would seem to indicate that this type of lignification may be general among plants of annual growth.

In order to separate and study the properties of the cellulose of the wheat fibre, the methods of Schulze, Cross and Bevan, and Lange (Zeits. angew. Chem. 1895, 561) were employed, the second-mentioned was, however, preferred.

When acted on by strong sulphuric acid according to E. Schulze's directions (Zeits. phys. Chem. **16**, 414), the cellulose, unlike cotton cellulose, did not wholly dissolve, and a very considerable discoloration was produced. The undissolved portion (nearly one-fifth) did not yield a measurable amount of furfural. The osazone formed was that of dextrose. From this it will be seen that the products of hydrolysis of the furfural yielding group do not appear. By the action of cold, dilute, sodium hydroxide, a filtrate and residue were obtained; the former, on neutralisation with hydrochloric acid was found to contain a substance bearing a general resemblance to wood-gum, in that it gave the characteristic reaction with phloroglucin. The residue constituted about 80 per cent. of the amount treated; a determination of furfural gave 3.34 per cent., equal to 2.67 per cent. of the original. Hence less than one-third of the dissolved substance was pentosan. On reviewing his experiments, the author believes that wheat cellulose contains about 10 per cent. of penta-anhydride, which appears to be chemically combined with a part at least of the hexa-anhydride (normal cellulose); also that the furfural yielding constituents of wheat are essentially pentosans in some form; further, that there is no serious error in considering the amount of furfural obtained as a measure of the total pentosans present.

*Part II. Analytical.*—It is customary in cereal analysis either to be content with the results of the Weende method or to determine in addition, the starch and, perhaps, the furfural obtainable, calculating the latter to pentosan. The author estimates starch, true pentosans, cellulose, lignin, and allied substances, and combines these determinations into the following scheme:—

5 grms. of the sample (previously extracted with ether) are stirred with about 100 c.c. of water for a few minutes, filtered, and washed.

<i>Filtrate.</i> —Add one-tenth its volume of 25 per cent. hydrochloric acid and heat in a reflux condenser for 2½ hours on a water-bath, or boil ½ hour on a sand-bath.	<i>Residue.</i> —Wash into a beaker with 100 c.c. of water (more if the proportion of starch is high), heat to boiling, cool partially, and invert with malt extract till starch disappears, filter, and wash.		
Clarify, if necessary, and determine the dextrose present in an aliquot portion by means of Fehling's solution and calculate to	<i>Filtrate.</i> —Treat as in the case of preceding filtrate and calculate the dextrose found to	<i>Residue.</i> —Boil ½ hour with 1.25 per cent. of sulphuric acid, filter, and wash with water and alcohol.	
	<i>Filtrate.</i> —Add sufficient sulphuric acid to make 2 per cent.; boil gently in reflux condenser for six hours; determine reducing power, calculate to pentose, and thence to	<i>Residue.</i> —Dry and weigh. In a duplicate residue, determine proteid (and ash) and correct the weight accordingly. Treat according to the method of Cross and Bevan ( <i>loc. cit.</i> ), dry, and weigh the residue.	
		Loss of weight corrected for proteids (and ash) equals	Residue, less proteid, if present (and ash), equals
		Lignin and allied substances,	Cellulose.
Soluble carbohydrates as dextrin.	Starch .....	Free pentosans .....	

The reducing powers were estimated by adding 25 c.c. of the solution to be tested to an excess of boiling Fehling's solution under the usual conditions of dilution, boiling exactly 2 minutes, collecting and determining the cuprous oxide by Lavenne's method as follows:—The reduced oxide contained in the filtering tube is dissolved with nitric acid, and washed thoroughly into a flask; an excess of sodium carbonate is added to the solution, and the precipitate dissolved with 1 c.c. of ammonia (0.96 sp. gr.). It is then titrated with a recently standardised solution of potassium cyanide until the colour disappears. Experiments showed that varying amounts of sodium nitrate did not affect the results.

The following method for the determination of furfural is essentially that of the Association of Official Agricultural Chemists. From 2 to 5 grms. of the sample are distilled with 100 c.c. of hydrochloric acid (sp. gr. 1.06), the distillate being collected in a graduated receiver. Each 30 c.c. lost by distillation is replaced by an equal amount of hydrochloric acid. This process is continued until a drop of the distillate produces no red coloration with aniline acetate. Eight to twelve distillations are generally necessary. Sufficient water is added to the distillate to bring it to a volume of 400 c.c., and for every 50 c.c. of water added, 10.2 grms. of sodium chloride are also added. The solution is then exactly neutralised with sodium carbonate

and stirred for half an hour with 10 c.c. of phenylhydrazine acetate, made by mixing 12 grms. of phenylhydrazine with 7.5 grms. of glacial acetic acid and diluting to 100 c.c. It is then allowed to stand until the following day, filtered into a glass filtering tube containing glass wool, and dried to constant weight at 55° to 60° C. in a current of dry air. Finally, the precipitate is dissolved in hot alcohol, the tube dried and weighed, and the loss of weight calculated as furfural hydrazone. For reducing to furfural and to pentosans the following formulae were used:—

Hydrazone  $\times 0.516 + 0.0604$ ..... Furfural.  
Furfural  $\times 1.81$ ..... Pentosans.

The factor for pentosans was obtained by averaging those of xylan and araban.

In Part III. the author discusses the digestibility and physiological value of the carbohydrates, and points out that little information is to be derived from the current methods of analysis, which simply divide this group into "nitrogen-free extract" and "crude fibre."—J. L. B.

*Molasses, Impts. in Extracting Sugar from, by Means of Barium Hydroxysulphide, and Recovering the Same from the Resulting By-Products.* W. Feld, Hommingen am Rhein, Germany. Eng. Pat. 16,009, July 20, 1896.

In order to avoid interruption of the continuous process for the extraction of sugar from molasses by barium hydroxysulphide, either alone or admixed with alkali hydroxide, the loss of sulphur is made up by mixing the residual liquid, separated from the precipitated barium saccharate, with alkali sulphate.

The barium sulphate is removed, reduced by carbon to barium sulphide, and again converted by water into barium hydroxysulphide to re-enter the cycle of operations. The liquor is then treated with carbonic acid to liberate sulphuretted hydrogen, which is converted into sulphuric acid, which can be used for decomposing barium saccharate, whilst alkali carbonate is obtained by calcination of the residue.—L. J. de W.

*Evaporating Apparatus, Improved.* R. H. F. Finlay, Belfast. Eng. Pat. 16,552, July 27, 1896.

See under I., page 661.

*Saccharine Solutions, Impts. in Apparatus for Clarifying.*  
L. F. Hauptman, New Orleans, U.S.A. Eng. Pat. 20,434, Sept. 15, 1896.

This is a device by which saccharine solutions from sugar-cane or other sugar-producing material may be rapidly clarified without contact with atmospheric air.

The apparatus comprises a number of connected heating vessels, arranged one above another, each vessel having in one end a receiving chamber and a discharge chamber, and at the opposite end a transferring and discharge chambers, and valves for closing the ends of certain of the tubes, and a partition extended longitudinally in the vessel, and having a space between its end and one of the tube sheets. There are also means for forcing a heating medium, like steam, downwards through the several heating vessels, and for forcing a liquid through in a direction opposite to that of the heating medium; a tank for receiving the heated liquid, and a cooling vessel similar to the heating vessels, with a tank for crude cold solution.

The heat, as soon as it strikes the liquors to be treated or clarified, separates the pure liquor from the impurities, and, to keep these impurities from settling in the tubes in transit, this liquor must have a rapid circulation through the tubes. To maintain this circulation when a smaller quantity is to be handled, certain of the tubes are closed by the valves provided. The crude cold solution is used for cooling the heated clarified liquor as it passes through the cooler to the settling tank.—L. J. de W.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Primary Fermentation and Attenuation—Brewing, Effect of Malt Meal on.* F. Cerny. *Oester. Brauer u. Hopfen-Zeit.* 1897, 119; *Zeits. f. d. ges. Brauw.* **20**, [21], 279—282.

From experiments made with samples (1.6 litre each) of 10.25 wort, pitched with 4 grms. of hops, and containing 0.2, 0.5, and 1.0 gm. of malt meal respectively, the author concludes that malt meal or malt extract may render useful aid to the brewer in critical cases when a suitable attenuation cannot be obtained by a change of yeast or by modifications of the brewing process. The yeast-strengthening properties attributed to the meal are, however, merely stimulative and not of a permanent character. A minimum quantity suffices to increase the attenuation at the end of the primary fermentation, but for raising the final attenuation, the effect (which is proportional to the amount of meal used) is best attained by adding the meal (or extract) before the secondary fermentation, since the yeast is thereby better protected. The best form of all is a cold aqueous extract of sterilised malt meal, concentrated diastase preparations not being available in sufficient quantity for practical use.

The actual effect of the above-named additions on the apparent attenuation in the primary and secondary fermentation was as follows:—

	Sample with			
	0.0 Per Cent. of Malt Meal.	0.2 Per Cent. of Malt Meal.	0.5 Per Cent. of Malt Meal.	1.0 Per Cent. of Malt Meal.
Apparent attenuation:				
Primary ....	59.90	76.39	78.11	78.73
Final .....	77.85	82.24	84.68	88.58
Increase ..	17.95	5.85	6.57	9.85

—C. S.

*Barley and Malt, Sugar and Starch Formation in.*  
I. Gross. *Wochenschr. für Brauerei*, 1897, 321—323.

The author, noting that dried malt always contains less sugar than the same malt when green, was led to carefully re-investigate the ferments present in germinating barley. Very careful precautions were taken to avoid all bacterial complications, and the presence of three distinct ferment actions was confirmed, namely, a starch dissolving, a cell-wall dissolving, and an inverting action. The cell-walls of the endosperm which are dissolved, are apparently hemi-cellulose with a pentose structure. Whether all these ferment actions are due to one or three different ferments is doubtful, but the author appears inclined to the former view.—A. L. S.

*Saké, the National Drink of Japan.* O. Schiewek.  
*Wochenschr. für Brauerei*, 1897, 337—339.

The preparation of saké has already been described in this *Journal* (1895, 670). The author has studied the growth and spore formation of the mould, *Aspergillus oryzae*, on different substances, and finds it to grow best on rice. It requires a temperature above 40° F. Several varieties of yeast were found with the rice mould, amongst which were an anomalous form and one with round spores.—A. L. S.

*Cereal Straws, The Carbohydrates of the.* C. F. Cross, E. J. Beran, and Claud Smith. *Proc. Chem. Soc.* 1897, [182], 150—152.

This paper deals with the results of further investigations of the products of acid hydrolysis of the cereal straws and of the celluloses isolated from them, including also the closely related esparto-cellulose. The results confirm those previously communicated (this *Journal*, 1896, 386), that

the furfural-yielding constituents (furfuroids) are selectively attacked, and for the most part (90 per cent.) dissolved; also, from the exceptionally high numbers for cupric reduction, that they must exist in solution in a fully hydrolysed form (monoses).

The solutions when neutralised, ferment with yeast: carbonic acid and alcohol are produced, and a proportionate effect upon the constants of the solution is shown (density, opacity, cupric reduction, and furfural). Under the conditions, the proportion of the celluloses fermented, amounts to 30 per cent. of the total dissolved solids. Similar conclusions are deducible from a recent paper by Tollens (J. für Landw., 1897, 106–107), in which the fate of malt furfuroids in beer-fermentations is discussed. The experimental numbers in this paper show the disappearance of a large proportion of these constituents in the process.

Since the pentoses entirely resist alcoholic fermentation, as shown by Tollens (Kohlenhydrate, ii.), and further confirmed by the authors, as well as by later observations of Tollens privately communicated, it is evident that the group of furfuroids thus fermented is constitutionally distinct from the pentoses.

Incidentally, and with regard to observations on alcoholic fermentation with mixtures of known hexoses and pentoses, the authors find that the latter remain unaffected in presence of hexoses undergoing fermentation. Under certain conditions, however, the pentoses are removed from solution by the yeast organism; the necessary condition appears to be that of "starvation," in the sense, *i.e.*, of the absence of hexoses. The disappearance of the pentose under these conditions is indicated by determinations of furfural and the fall of the furfural numbers. This phenomenon appears to be the simple one of assimilation by the yeast organism, as shown by Bokorny (Dingler's Polyt. J., 1897, v. 303; this Journal, 1897, 345). The pentose undergoes constitutional change in such assimilation, as the yeast shows no increase in its normal small furfural number.

The authors further discuss the question of the constitution of furfuroids thus shown to yield alcohol on fermentation, and conclude that the hypotheses of the existence of methylene ethers of the pentoses, or pentose formal, affords, up to the point arrived at, a consistent view of their differentiation from the pentoses.

*Laccase, Intervention of Manganese in the Oxidising Actions of.* G. Bertrand. Bull. Soc. Chim. 1897, 17, 619–624.

The ash of this ferment contains manganese, the quantity of which was determined by conversion into permanganic acid by boiling with nitric acid and lead peroxide, and comparison of the depth of tint in the colorimeter. The amount of oxygen absorbed by a solution of hydroquinone in presence of this laccase is roughly proportional to the percentage of manganese. The laccase extracted from lucerne (*Medicago Sativa L.*) contains a very small proportion of manganese; its oxidising power is much increased by the addition of manganese sulphate. In this experiment, manganese cannot be replaced by any other metal, not even by iron.—A. C. W.

*Acetic Bacterium, A New.* Zeidler. Zeits. für Spiritus-ind. 1897, 20, [21], 164, and [21], 171–172.

The properties of this bacterium have led the author to name it *termobacterium aceti*. It produces acetic acid from alcohol, and in its form and motile property it agrees with Cohn's *termobacterium*; but, on the other hand, it differs from the latter in that it has a great tendency to assume involution forms. The motile property is retained in beer cultures until the acidity is equal to 30–35 c.c.  $\frac{1}{10}$  N soda solution to 10 c.c. of the liquid, whilst in wort cultures the same property is lost when the acidity reaches 4–5 c.c. In addition to acetic the *termobacterium* also produces a fixed acid (apparently lactic acid) when grown in beer-wort and solutions containing dextrose, the maximum limit of the fixed acid corresponding with 5 c.c. of  $\frac{1}{10}$  N soda to 10 c.c. of liquid. In the presence of alcohol, both acids are formed; thus a wort free from alcohol, showed an acidity after a month, equal to 1.4 c.c.  $\frac{1}{10}$  N soda, whilst with

the addition of alcohol the acidity reached 59.7 c.c., of which 4.5 were due to fixed and 55.2 to volatile acid. The volatile acid is only produced in alcoholic liquids. The *termobacterium* also has the power to convert acetic acid into carbon dioxide and water, but it loses this property when the acidity exceeds 43 c.c. of  $\frac{1}{10}$  N soda. On wort gelatin it gives a weak growth which does not liquefy the gelatin; in stab cultures it shows a distinct growth, which afterwards becomes confined to the surface, showing the bacterium to be aerobic. The most favourable temperature for the growth and activity of the organism appears to be about 25°. Large quantities of alcohol prevent its development, and in a wort to which 16 per cent. or more alcohol was added the organism perished; with 6 per cent. of alcohol and after 10 days' growth the yield of acid was greatest. *Termobacterium aceti* is much less resistive than the ordinary acetic bacteria; its cultures in beer and wort perish when kept for six months at the ordinary temperature, and in the presence of the true acetic bacteria, it soon becomes suppressed.—A. K. M.

*Fermentation, Volatile By-products of.* A. C. Chapman. J. Fed. Inst. Brewing, 1897, 3, 240–254.

AFTER discussing the nature and probable origin of the volatile by-products of fermentation, the author describes the methods which he employed to estimate the higher alcohols, compound ethers, furfural, and aldehyde. A quantity of the beer, varying from four to eight litres, was distilled until the whole of the alcohol was obtained in a small volume (500 to 600 c.c.). The distillate was made up to a definite volume, and aliquot portions were taken for the estimation of the higher alcohols, compound ethers, and furfural. The higher alcohols were determined by extraction with carbon tetrachloride and conversion into the corresponding fatty acids; the compound ethers by saponification,—the results being expressed in terms of acetic ether (ethyl acetate)—the furfural and aldehyde by the aniline acetate and rosaniline sulphite reactions respectively. The following table shows some results obtained with English beers, the percentages being expressed in parts per 100 of proof spirit:—

	XXXX Beer.	Light Bottled Beer (carbonated).
Higher alcohols (as amyl alcohol) ...	0.250	0.1300
Compound ethers.....	0.036	0.0440
Furfural.....	0.002	0.0006
Aldehyde.....	Trace.	Trace.

	Bitter Beer.	Bottled Beer.	Mild Ale.
Higher alcohols (as amyl alcohol)....	0.140	0.0840	0.0700
Compound ethers.....	0.052	0.0370	0.0240
Furfural.....	0.002	0.0018	0.0006
Aldehyde.....	Heavy trace.	Heavy trace.	Trace.

Analyses of some samples of beer which had been in bottle for many years, showed high percentages of compound ethers, to which the marked flavour of the samples was due. The amount of higher alcohols was not greater than in new beers—a result which is opposed to Lindet's supposition that these substances are formed chiefly when the vigorous primary fermentation is over and the yeast is to some extent exhausted. Experimental evidence is brought forward showing that with high-fermentation temperatures, there is a distinct increase in the percentages of the higher alcohols and generally of the compound ethers.—J. L. B.

*Malt, Note on the Value of the Soluble Carbohydrates as an Indication of Forcing of.* L. Briant. J. Fed. Inst. Brewing, 1897, 3, 222–228.

It appears to be the opinion of some brewers that a high proportion of soluble carbohydrates is certain evidence of a forceful malt; the object of the author's communication is to show that the facts do not justify quite so definite a

conclusion. It is pointed out that the amount of root produced on the floor has an intimate connection with the quantity of matter, soluble in cold water, yielded by the malt. The author's experiments demonstrate that malts grown with short roots on the cool system contain more matter soluble in cold water than those with long roots. High proportions of soluble matter may be objectionable, but it is contended that they are not necessarily an indication of a forced malt. Malts produced on sound lines may contain as much as 17.5 to 18 per cent. of soluble carbohydrates, and it is suggested that a limit higher than that now commonly employed should be established. Attention is also drawn to the fact that certain types of barley naturally give malts having larger proportions than others of soluble carbohydrates, even when made on the best possible lines, so that a proportion which indicates forcing in one sample, might not do so in another.

On the other hand, the author is of opinion that a small proportion of soluble carbohydrates does not necessarily indicate that a malt has not been forced. The author instances a sample of malt which was "worked up very roughly with about 12 gals. of sprinkling water on the floors at about 68° F., whilst during withering the temperature rose to nearly 90° F., and yet the percentage of soluble carbo-

hydrates was not very abnormally high, being 16.7 per cent." He is inclined to think that these carbohydrates were absorbed by the root, which was unusually large. To detect forcing, the determination of soluble carbohydrates is not sufficient; but if several considerations, such as the diastatic power, the tintometer value, and nitrogenous matter soluble in cold water, be taken into account, the author considers that "forcing" may be detected by analysis.—J. L. B.

*Organic Products, Industrial Distillation of.* E. Barillot. Bull. Soc. Chim. 1897, 17, 635—638.

The principle upon which the working of the apparatus is based is that when a complex vapour is led through a bath at a constant temperature, those substances are condensed whose boiling points lie below the bath temperature. Thus, by the use of a series of baths, it is theoretically possible to separate complex mixtures.

In the figure, the liquid to be distilled—wine, must, or wood spirit—is heated, and then enters the column A, from which it proceeds into the heated vessel B. The alcohol vapours are evolved in the column D, and rise into the analyser E, the higher boiling products, mixed with alcohol, run into C, where the alcohol is distilled off and the oil-

left conducted into H. The light vapours are further analysed in F. The analysers are kept at a constant temperature by baths of boiling liquid surrounding them, the baths being connected with the reflux condenser G.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

## (A).—FOODS.

*Tea, Chinese; On the Relation between the Amount of Caffeine in and Quality of.* L. Graf. Forschungs-Ber. 1897, 4, [4], 88—89.

It has been pointed out by Kellner that in the living tea-plant the amount of caffeine in the leaves decreases with the growth. Since the finer kinds of tea consist of the younger leaves, the author has made experiments to determine whether the percentage of caffeine could give any indication as to the quality of the tea. Two varieties were examined, and the caffeine was determined in the aqueous extract by precipitating the tannin with basic lead acetate, filtering, removing the lead, concentrating the filtrate after the addition of sodium acetate, filtering, and extracting the alkalioid with chloroform. As thus obtained, the caffeine was but slightly coloured, and contained only traces of impurities.

The results, calculated on the air-dried tea, were:—

	Caffeine.	Price.
	Per Cent.	Marks.
Souchong 206.....	2.96	1.30
" 273.....	3.10	1.80
" 266.....	3.53	3.15
Congou 27.....	2.82	1.80
" 269.....	3.70	2.40
" 268.....	4.09	3.10

Thus in both kinds of tea the amount of caffeine increases with the quality and commercial value.—C. A. M.

*Milk of Cows or other Domesticated Animals, An Improved Treatment, to render it Suitable as Food for Infants and Children.* A. Backhaus, Goettingen, Germany. Eng. Pat. 16,016, July 20, 1896.

THE milk is separated into cream and skim milk, and the latter made feebly alkaline and treated at a suitable temperature with a ferment, such as trypsin, in sufficient quantity to convert about half the casein into soluble albumin in about 30 minutes, and with a ferment like rennet to precipitate the unacted-upon casein. By raising the temperature to from 70° to 80°, the trypsin and rennet are subsequently rendered inert. The precipitated casein is removed and cream and milk-sugar added to the treated milk, so as to make it resemble human milk. The separated cream may be mixed with water, milk, and milk-sugar, to resemble ordinary milk.—C. A. M.

*Butter and other Foodstuffs, An Improved Process for Use in Preserving.* Jean, known as Bernard Iribarnégaray, Bayonne, France. Eng. Pat. 3830, Feb. 12, 1897.

THE butter or other food material is impregnated with or kept in a solution of 5 to 20 grms. of purified sodium fluoride ("crysoléine") in 1,000 grms. of water.—C. A. M.

## (B).—SANITATION; WATER PURIFICATION.

*Woolcombers' Suds, The Treatment of.* Public Health J., July 14, 1897, 219.

IN view of the prominence which has been given in the Bradford Bill, now before Parliament, to the question of the treatment and disposal of "suds" from the woolwashing bowls in combing sheds, considerable interest attaches to a process which has been introduced at the works of Messrs. William Scaife and Co., Ltd., woolcombers, Laisterdyke. The process is exceedingly simple, and apparently successful. The suds, after being run off from the washing bowl, are allowed to stand for about half an hour in a settling tank, to permit the sand and solid matter to fall to the bottom. The liquor is then pumped into a tank, very much like a wash bowl, in the bottom of which is a system of pipes through which compressed air is forced. About 1 gall. of sulphuric acid to every 700 galls. of suds is added before the "blowing" begins. The violent aeration of the liquor which ensues, quickly brings the grease to the surface in the form of thick foam or froth, and a set of boards, carried on an endless chain, scrape this off and carry it away over one end of the tank. The blowing is continued so long as any froth rises, which is found to be just so long as there is any grease left in the water. The foam, which contains only about 5 per cent. of water, is treated just as the magna obtained in the usual way by precipitation, is dealt with—by pressure in a steam press. The liquor from which the grease has been extracted is treated with lime, in the proportion of about 125—150 grains of slaked lime per gallon of acid water. This neutralises the acid and makes the water quite clear and inodorous, so that it may be turned into the public sewers without being a nuisance. F. W. Richardson estimates the cost for lime at about 2l. 10s. per million gallons of acid effluent. The apparatus is not costly, and is easily worked; and as the suds can be dealt with—the grease being extracted and the liquor cleared within two hours of their leaving the wash bowl—no nuisance can be created.

## PATENTS.

*Purifying Air and Separating Matter from Gaseous Fumes, Impts. in Apparatus for.* S. Edwards, Manchester. Eng. Pat. 10,942, May 21, 1896.

THE gases to be washed or purified are caused to pass through a series of tanks against a stream of water, in which are partially immersed rotating conveyor worms or vanes, against which the gases impinge, and deposit the solid particles.—O. H.

*Filtering Sewage, Impts. in Presses for.* W. T. and J. Wostenholme, Lancaster. Eng. Pat. 12,735, June 10, 1896.

In presses formed of a number of metal plates having grooved faces covered with sackcloth, trouble is experienced in consequence of the sackcloth becoming forced into the grooves, and seriously reducing the rate of filtration. To prevent this, one or more perforated plates of steel or other metal are interposed between each of the grooved faces and the sackcloths; or two or more of such perforated plates are stayed apart from one another in a cast-iron frame, and held together by bolts, a passage being left in the middle for inlet of the sewage.—L. A.

*Furnaces for Consuming, Deodorising, and rendering Innocuous Foul Air, Smoke, and Objectionable and Dangerous Gases generally; Impts. in.* S. G. Smith, Plainfield, New Jersey, U.S.A. Eng. Pat. 9905, April 20, 1897.

The gases, ill odours, &c. from gasworks, slaughter-houses, &c., to be consumed, are blown, along with air and steam, into a saddle chamber over the boiler, and pass thence, through apertures ranged around the firebox, into the furnace, where they are ignited. The heat of combustion of these matters is utilised.—C. S.

## (C).—DISINFECTANTS.

### PATENTS.

*Formic Aldehyde, Impts. in the Production of Vapours of and in Apparatus therefor.* J. J. A. Trillat, Paris. Eng. Pat. 17,177, Aug. 4, 1896. (Under Internat. Convention.)

A CURRENT of compressed air from a gasometer, pump, or any suitable appliance, is driven through a water-jacketed closed vessel containing methyl alcohol heated to a constant temperature by a gas or spirit flame. The stream of air and alcohol vapour thus produced, is led into the "oxidiser-distributor."

The latter consists of a row or battery of oxidising cylinders, constructed like Bunsen burners, fixed upon a chamber. Each oxidising cylinder contains a tube of retort carbon filled with copper, silver, or platinum wire gauze, or platinised asbestos, &c., and is warmed to start the oxidation, which soon raises the gauze to incandescence; the admission of air is then regulated, so that the incandescence does not exceed a cherry-red.

Several modifications are described, the object in all being to separate the alcohol vaporised from the oxidiser, so that the former may be outside the place to be disinfected, the latter alone being placed inside.—L. A.

*Dipping Sheep. An Improved Composition or Mixture for, and for analogous Purposes.* R. Mackill, Glasgow. Eng. Pat. 448, Jan. 7, 1897.

NICOTINE extracted from tobacco is used instead of tobacco itself. A composition suitable for 1,000 sheep contains 1 lb. of nicotine extract (80 per cent.), 5 galls. of cresol, and 50 galls. of water. This, after thorough mixing, is further diluted with 150 galls. of water.—L. A.

*Aldehydes, Impts. in and connected with Apparatus for Producing Vapours of.* E. Fournier, Paris. Eng. Pat. 7887, March 26, 1897.

THE apparatus consists of a glow-lamp, comprising a reservoir for the reception of the alcohol, an annular wick-tube, a central siphon tube for the admission of air, and a movable screen. Over the wick-tube is a disc of platinum-wire gauze, which can be raised or lowered by suitable means. The lamp is first lighted to raise the gauze to incandescence, and then extinguished, after which flameless combustion is continued by the agency of the platinum gauze. In order to disguise the unpleasant odour, a cup is provided above the flame for the reception of some solid, volatile, aromatic substance; or a disc of asbestos may be used, on which liquid scents may be poured.—L. A.

*Grain, Seeds, and other Vegetable Substances; Impts. in the Method of and Means for Disinfecting and Preserving.* M. Clajus, Ober-Altwaltersdorf, near Habelswehlt, Germany. Eng. Pat. 11,183, May 8, 1897.

THE grain is placed in a revolving wire-gauze drum contained in the upper part of a wooden outer casing, and sulphur is burnt in the lower part. The sulphur dioxide passes up through the grain and escapes through a flue at the top. A very short exposure to the fumes proves a very effective protection against diseases in the grain and the attacks of vermin thereon.—L. A.

## XIX.—PAPER, PASTEBOARD, Etc.

*Steamers for Wood, Destruction of Flange Bolts in.* Papier Zeit. 22, [58], 2065, July 22, 1897.

IN some vertical steamers at the Paper Mills, Neumühle, near Meisbach, it was noticed that the wrought-iron bolts of the upper flanges were badly, and those of the lower flange slightly corroded, whilst the cast-iron plates were almost uninjured. In these steamers the wood is put in at the top, and during the process of steaming, a liquid collects at the bottom, which covers the lower flange. This liquid consists of condensed steam, acids, and other substances extracted from the wood. The authorities of the Chemical Experiment Station at Karlsruhe traced the corrosion to the combined effects of acid, steam, and air. The liquid at the bottom contained 1.65 grms. of acid (calculated as acetic) to 1 litre, 1.21 grms. of which was volatile in steam. That the bolts of the bottom flange were not badly corroded is due to the fact that they were only subjected to the action of a dilute solution of acid, whilst the upper flanges were subjected to the combined action of volatile acid, steam, and air. The plates were only slightly attacked, as cast iron offers more resistance to the action of the acid vapours. The remedy is to carefully examine the screws from time to time and replace the injured ones, but an asphalt varnish might prove of benefit. This corrosion is liable to cause dangerous explosions, and even with copper-lined steamers, the acid vapours might penetrate some defect in the lining.

The authority of the *Papier Zeitung* does not recommend the use of a varnish, but rather the use of phosphor-bronze bolts in place of iron ones.—S. P. E.

*Paper Mills, Hot-Water System in.* Papier Zeit. 22, [56], 1962.

AS it is detrimental to rags and sulphate pulp to allow the caustic lye to stand in contact with the pulp after boiling, it is preferable to wash it at once in the digester with hot water. If cold water be used, the encrusting or resinous matters are precipitated on the fibres, and are then difficult to remove, and make the pulp difficult to bleach. Since heating the wash water by steam is expensive, and as hot water can be provided in a paper mill without any special expense for fuel, it is better to have a system by which this hot water can be conveyed directly to the digesters and washing engines for washing purposes. By thus using hot water, the temperature of the half-stuff can be regulated so that bleaching can be effected without the use of acid, a stronger fibre being thus obtained, and expense saved. Also in coloured papers, heating by steam is liable to affect the dyes, whilst hot water is not.

The writer noticed that during a flood which caused the paper machines to be run with hot water, though frothing was rather heavy, the pulp did not stick to the top couch roll, as it did when cold water was used.—S. P. E.

*Paper, Testing.* W. Herzberg. Mitt. k. t. Versuchsanst. zu Berlin, 15, [1], 85—88.

1. *Permeable Spots in Paper.*—The paper in question—a white writing paper prepared from clean rags and dressed with resin paste—allowed the ink to run through in places and give rise to coloured patches 1 to 3 mm. in diameter on the underside. These places were detected by the white appearance they exhibited on dampening the sheet, and from their behaviour towards Congo Red and Methyl Orange in faintly acid solution, revealed the presence of a substance

with an alkaline reaction. On treatment with iodine dissolved in potassium iodide, the initially blue coloration produced by the starch gradually changed to brown from the liberation of iodine, the blue being restored by weak acid, and thus indicating free chlorine (nitrous acid being out of the question), which was found, together with lime, on extracting the paper with water. This behaviour indicated the presence of traces of bleaching powder, probably due to lack of care in cleansing the materials after bleaching.

—C. S.

#### PATENTS.

*Multiple-Pulp Papers, Impts. in the Manufacture of.* W. A. Kershaw and the Medway Paper Mills Co., Ltd., Maidstone, Kent. Eng. Pat. 12,682, June 9, 1896.

THE two or more differently coloured pulps are contained in separate stuff chests. The second and third layers of pulp are delivered to boxes placed over the wire of the machine at required distances from the end. Each of these boxes is provided with an adjustable opening to deliver the pulp upon the machine wire in an opposite direction to the running of the wire. The vacuum boxes take off the water from the different layers of pulp in the usual manner, forming a single sheet which is passed through the machine and finished in the ordinary way.—S. P. E.

*Digesters, Cellulose Boilers, and like Steam Boiling Apparatus; Impts. in.* C. Kellner, Vienna, Austria. Eng. Pat. 12,910, June 11, 1896.

THE inside of the boiler is coated with shallow hollow iron plates or sections, arranged after the manner of the staves of a barrel, and corresponding to the form of the shell of the boiler. The boiler itself is protected from the effects of the liquid to be boiled, by a layer of refractory material, such as cement, between the shell of the boiler and the before-mentioned plates. These plates are connected by bent pipes at their upper parts, and steam is supplied through a pipe extending through the shell of the boiler. The water of condensation is removed from the lower parts of the sections by pipes connected with a common outlet pipe.—S. P. E.

*Fibre, Paper, Tissues, and the like; Impts. in the Method of Waterproofing Fabrics made of.* J. Waugh, Bradford, Yorkshire. From Amos and Co., Frankfurt a/M., Germany. Eng. Pat. 15,893, July 18, 1896.

THE improvements consist in saturating the fabrics with a solution of the waterproofing salts (preferably the oleate or other fatty salts of aluminium) in benzene or other readily evaporating solvent, and subsequently evaporating the solvent.—C. A. M.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Cerium Oxide, The Purification of.* Wyrnoff and Verneuil. Comptes Rend. 124, 1230—1233.

BESIDES the lower oxide (formulated by the authors  $\text{CeO}$ ) and the higher one (formulated  $\text{Ce}_2\text{O}_3$ ), there exists another,  $\text{Ce}_2\text{O}_4 = \text{Ce}_2\text{O}_3 \cdot 3\text{CeO}$ , very stable, which is formed when cerium compounds are treated in solution with chlorine, according to Mosander, or fused with nitre, according to Debray. Still more stable and more readily formed are compounds of the formula  $\text{Ce}_2\text{O}_4 \cdot 3\text{MO}$ , where  $\text{M} = \text{La}$  or  $\text{Di}$ . These oxides are broken up completely by ammonium nitrate, according to the following procedure:—The oxides obtained by calcining the oxalates are dissolved in warm nitric acid, evaporated to a syrup to remove acid, and then diluted largely with water, so as to have about a 4 per cent. solution of the oxides. Adding now ammonium nitrate till the solution contains some 5 per cent., all the  $\text{Ce}_2\text{O}_4$  precipitates as basic nitrate, while the oxides  $\text{MO}$  remain dissolved. The precipitate, well washed with ammonium nitrate, is free from lanthanum and didymium, as well as from oxides of the yttrium group. The solution, precipitated with oxalic acid and the precipitate treated by a repetition of this process, yields another portion of the cerium, and so on. If the mixture of oxides contains as much

as 50 per cent. of cerium, it will not dissolve in nitric acid; in this case the oxalates are dissolved in nitric acid, hydrogen peroxide and then ammonia added, and the liquid boiled. The precipitated hydroxide, after washing, is dissolved in nitric acid and the operation conducted as above. The precipitate obtained by adding ammonium nitrate for the first time (75 per cent. of the total cerium), contains all the thorium that may have been present. To remove this, the cerium as oxalate or nitrate as nearly neutral as possible, is treated once or twice with a strong solution of ammonium carbonate containing free ammonia, which dissolves all but a trace of thorium; and this trace is got rid of by crystallisation of the sulphate in neutral solution at  $60^\circ$ . Iron, the only remaining impurity, is now removed by precipitating the chloride or nitrate in warm acid solution with oxalic acid, or by keeping the sulphate for some time at a temperature of  $400^\circ$ — $450^\circ$ .

The atomic weight of such a product is constant; the oxide itself, calcined at a high temperature, is absolutely white.—J. T. D.

*Cerium Oxide, Preparation of.* H. Moissan. Comptes Rend. 124, 1233.

A NOTE on the previous paper. Cerium oxide, giving no absorption spectrum in strong solution, is converted into carbide in the electric furnace. This carbide, in fine powder, was treated with weak nitric acid in quantity only sufficient to decompose a portion. A second attack, by a quantity of acid not quite enough to dissolve the whole, gave a solution of pure cerium, the whole of the iron being in the first solution and the whole of the thorium in the unattacked residue.

By simple calcination of the evaporated second portion, a cerium oxide is obtained perfectly white.—J. T. D.

*Kola Nuts, Composition of.* Report on the Agricolt. Work in the Botau. Gardens, British Guiana, 1893-4-5. 121—122.

THE composition of the kola nuts from Land of Cacaoan, Demerara River, is given as follows:—Water, 49.49 per cent.; fat, 0.82 per cent.; albuminoids (containing 0.496 per cent. of nitrogen), 3.1 per cent.; amides, &c. (containing 0.019 per cent. of nitrogen), 0.12 per cent.; caffeine (containing 0.472 per cent. of nitrogen), 1.69 per cent.; sacrose, 1.93 per cent.; glucose, 0.54 per cent.; pectose, gums, acid matters, &c., 4.14 per cent.; starch, 24.3 per cent.; digestible fibre, 7.73 per cent.; woody fibre, 4.19 per cent.; iron peroxide, 0.07 per cent.; magnesia, 0.08 per cent.; lime, 0.14 per cent.; potash, 0.69 per cent.; soda, 0.03 per cent.; silica, 0.1 per cent.; sulphuric anhydride, 0.16 per cent.; phosphoric anhydride, 0.34 per cent.; and chlorine, 0.06 per cent. The amount of alkaloids appeared to be somewhat above the average, but the greater part of the caffeine in fresh kola nuts was found to be in the form of a glucoside and not as the free base. It was found that the acid taste frequently observed in prepared kola might be avoided to a considerable extent by thinly slicing the fresh nuts and drying them in a current of air at  $140^\circ$ — $160^\circ$  F., finishing the drying at  $220^\circ$  F. The acid matter appears to become oxidised and there is an increase in the amount of colouring matter in the nuts.—A. S.

*Chelidonine.* A. J. G. Tyrer. Apoth. Zeit. 12, 442; Pharm. J. 1897, 59, 21.

THE material operated upon was obtained partly by E. Merck and partly prepared from fresh chelidonium roots. In both cases the base crystallised from alcohol in transparent tables melting at  $135^\circ$  C. Results corresponding to those of Henschke and Gelle (Archiv. Pharm. 1888 and 1890) were obtained with regard to the composition of the base ( $\text{C}_{20}\text{H}_{19}\text{NO}_5 + \text{H}_2\text{O}$ ) and its behaviour towards reagents. Methyl iodide had very little action on the base at  $100^\circ$  C., but at  $130^\circ$ — $140^\circ$  C., a crystallisable compound was obtained having the composition  $\text{C}_{20}\text{H}_{19}\text{NO}_5\text{CH}_3\text{I}$ . By the behaviour of the base towards acetic and benzoic anhydride, it was found that only one of the five oxygen atoms is present in the base as an OH group. The compounds obtained

had the following composition:—mono-acetylhelidonine,  $C_{20}H_{18}(C_2H_3O)NO_4$ ; mono-benzoylhelidonine, —

The elimination of water observed by Henschke could not be confirmed. A crystalline oxime,  $C_{20}H_{17}NO_4 \cdot N \cdot OH$ , was obtained by treating the base with hydroxylamine.—A. S.

*A Menthoglycol.* P. Barbier and G. Leser. *Comptes Rend.* 1897, **124**, 1308—1311.

When citronellal is shaken with 10 times its weight of 5 per cent. sulphuric acid for 12 hours, it becomes viscous, but remains colourless. The product, smelling strongly of mint, on fractionation under a pressure of 10 mm., yields isopulegol and a body of the formula  $C_{10}H_{20}O_2$  boiling at  $144^\circ$ — $145^\circ$  under 10 mm. pressure, and after crystallisation from petroleum spirit, melting at  $81^\circ$ — $81.5^\circ$  C. The substance appears to be a glycol capable of losing water with formation of isopulegol; the authors give it the name menthoglycol and have re-obtained it from isopulegol.

—A. C. W.

*Oil of Celery, Constitution of the Odoriferous Constituents of.* G. Ciamician and P. Sillier. *Ber.* 1897, **30**, [11], 1419—1424.

From the high boiling portions of oil of celery, sedanolie and sedanolic acids were isolated (this Journal, 1897, 462). Sedanolic acid,  $C_{12}H_{20}O_4$ , is a ketone, and from the decomposition products of its oxime the formula—

is deduced. It is not changed on heating with dilute sulphuric acid, it is reduced by sodium to the alcohol-acid,  $C_{12}H_{22}O_4$ , which is stable towards permanganate, and hence is saturated. On oxidation with permanganate, normal valeric, normal glutaric and oxalic acids are obtained.

Sedanolic acid,  $C_{12}H_{20}O_4$ , is reduced by sodium and alcohol to the same saturated alcohol acid, but by the action of sodium amalgam sedanolie acid gives an oily acid of the same constitution as sedanolie acid, but not identical with it. Sedanolie acid oxidised by permanganate in the cold, is chiefly converted into *o*-oxymethyl-benzoic acid, the lactone of which also possesses a celery-like smell.

In oil of celery, sedanolie acid is probably contained as the anhydride—

tetrahydrobutyl phthalide. Bodies of similar constitution appear to have the celery odour.—A. C. W.

*Caffeine, Some Properties of.* E. Tassilly. *Bull. Soc. Chim.* 1897, **17**, 596—599.

An examination of certain properties of caffeine which are of importance in its determination.

1. Caffeine hydrate does not lose the whole of its water at  $150^\circ$ , the temperature at which it is partially volatile. At  $110^\circ$  the anhydrous substance does not lose weight, but the hydrate heated to this temperature loses 6.93 per cent.

2. When an aqueous solution of caffeine is evaporated on the water-bath, none is volatilised with the steam.

3. In aqueous solution caffeine is decomposed by lime at  $100^\circ$ , ammonia being slowly evolved. Under the same conditions magnesia causes no evolution of ammonia.

4. The partition of caffeine between its solvents ceases to be normal when the liquids contain extractive substances as in the treatment of natural products.—A. C. W.

*Dextro-rotatory Licarhodol.* P. Barbier and G. Leser. *Bull. Soc. Chim.* 1897, **17**, 590—596. See this Journal, 1896, 613.

The existence of this alcohol having been doubted, the authors now give a more detailed account of their work.

Pure licareol, boiling at  $86^\circ$ — $88^\circ$  C. under 10 mm. pressure and with the rotation  $a_D = -12^\circ.45$ , was heated at  $150^\circ$ — $160^\circ$  for 8 hours with its own weight of acetic anhydride. After removal of acetic acid and distillation under 10 mm. pressure, four fractions were obtained,  $50^\circ$ — $80^\circ$  containing terpenes,  $80^\circ$ — $105^\circ$  containing unaltered

licareol,  $105^\circ$ — $130^\circ$  containing the ester, and a higher fraction containing an ether ( $C_{10}H_{17}O_2$ ), boiling at  $115^\circ$ — $150^\circ$  under 10 mm. The ester, which boils at  $119^\circ$ — $120^\circ$  under the same pressure, was saponified by the gradual addition of alcoholic potash, excess being avoided. The alcohol was precipitated by water; after two distillations it boiled at  $112^\circ$ — $114^\circ$  under 9 mm., had the density 0.904 at 0, the rotation for sodium light  $a_D = +1.8^\circ$ . The yield was 800 grms. from 3 kilos. of licareol.—A. C. W.

*Asafetida, Composition of.* J. Polásek. *Archiv. der Pharm.* 1897, [2], through *Pharm. Zeit.* 1897, **42**, 240.

The percentage composition of pure tears of amygdaloid asafetida was found to be:—Resin, soluble in ether (ferulic acid ester of asaresinol-tannol), 61.40; resin, insoluble in ether (free asaresinol-tannol), 0.60; gum, 25.1; volatile oil, 6.7; vanillin, 0.06; free ferulic acid, 1.28; moisture, 2.56; and foreign matter, 2.5.

The formula for asaresinol-tannol is  $C_{21}H_{34}O_8$ . It gives a benzoyl derivative,  $C_{21}H_{32}O_8 \cdot C_6H_5CO_2$ , and an acetyl derivative,  $C_{21}H_{32}O_8 \cdot CH_3CO_2$ . Asaresinol-tannol contains therefore an hydroxyl group,  $C_{21}H_{34}O_8 \cdot OH$ . On hydrolysing with sulphuric acid, umbelliferone is obtained.

—J. O. B.

*Tolu Balsam, Spurious.* J. O. Braithwaite. *Pharm. Journ.* 1897, **58**, 307.

The price of Tolu balsam being at present very high, and the genuine article apparently but rarely met with in the drug market, it is not surprising that fictitious samples are occasionally imported. A considerable quantity of the balsam under notice has recently reached the port of London.

It differs very markedly in physical characters from the genuine substance, being soft and much more viscid, especially when chewed. Under the microscope but few crystals were to be seen in a thin layer of the substance. With genuine Tolu balsam, the field is crowded with them. Extracted with successive quantities of boiling water, it yielded 1.15 per cent. of crystalline acid on cooling. This acid was fractionally crystallised from boiling water, when each fraction was found to melt sharply at  $133^\circ$  C., and to consist wholly of cinnamic acid. Genuine Tolu balsam, under similar treatment, gave 4.2 per cent. of cinnamic acid. Treated with carbon bisulphide, the doubtful sample gave 61.4 per cent. of soluble matter as a fragrant, brown, transparent, viscid mass, with a total acid number of 274 when saponified with alcoholic potash. Genuine Tolu balsam gives with bisulphide a perfectly white crystalline residue, the total acid number of which should not fall below 300. It is evident that the product referred to cannot be regarded as the true official balsam of Tolu derived from *Myrrorhylon toluifera*, and therefore it should not be used for medicinal purposes; it may be derived from some nearly allied species, since it differs materially from substituted or factitious samples previously reported on by the author and others.

—J. O. B.

*Argentol.* *Pharm. Zeit.* 1897, **42**, 243.

“ARGENTOL” is a synthetic antiseptic, consisting of a combination of silver with quinosol. It forms a yellowish almost odourless powder, sparingly soluble in water or in alcohol. Its composition is  $C_9H_7N(OH)SO_3 \cdot Ag$ .

—J. O. B.

*Sodium Tetraborate, So-called, and Magnesium Tetraborate.* *Pharm. Zeit.* 1897, **42**, 191, 201, 223.

CONSIDERABLE confusion has arisen through the incorrect application of the term tetraborate of sodium to several distinct preparations of borax and boric acid. Chemically the term tetraborate of sodium can only be correctly applied to borax, and yet it has been used by Kaufmann to designate a preparation of borax 5.5 parts, with boric acid 10 parts. Conrad states that the same substance should be prepared from two molecular weights of boric acid and one of borax. Janicke-Görlitz again describes the salt as being prepared from equal parts by weight of borax and boric acid dissolved in an equal quantity of water. This last preparation has the property of crystallising out very

slowly from warm saturated solutions, so that when injected into a cavity, such as the aural passage, it slowly solidifies, and thus forms a permanent antiseptic plug.

Magnesium tetraborate is prepared as a solution or as a white powder, soluble in four parts of hot water. Kuchen-thal gives the following directions for its preparation:—Mix boric acid, in powder, 25 parts; magnesia, 4 parts; with water, at least, 150 parts; warm until complete solution is effected, filter from any excess of magnesia left insoluble; this solution is intended for application to the diphtheritic membrane or for internal administration; when required in the powdered form, the same ingredients are merely rubbed together with a little water and dried at a low temperature.—J. O. B.

*Ether, Aldehyde in, Method for the Determination of.* Maurice François. J. Pharm. Chim. 1897, 5, 521.

See under XXIII., page 704.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Chloride of Nitrogen.* W. Hentschel. Ber. 1897, 30, [11], 1434—1437.

INDIFFERENT solvents diminish the explosive nature of chloride of nitrogen. A 10 per cent. benzene solution can be lighted or poured over a red-hot plate without remarkable appearances of decomposition. The substances which cause chloride of nitrogen to explode, react very rapidly on its solutions, but mainly in a controllable manner; the action of phosphorus on a concentrated solution alone assumes an explosive character. The solutions are sulphur-yellow, strongly refractive liquids, quickly decomposing in sunlight, but only slowly in the dark, the rate of decomposition being but little dependent on the nature of the solvent. In the decomposition of the benzene solution, free nitrogen and benzene hexachloride are formed; from the carbon bisulphide solution chloride of sulphur is obtained; from chloroform, chlorine, hydrochloric acid, and ammonium chloride. Chloride of nitrogen dissolved in ether is completely converted into ammonium chloride.—A. C. W.

### PATENTS.

*Pyroxylin Smokeless Explosives, Impts. in the Manufacture of.* H. Maxim, London. Eng. Pat. 16,858, July 29, 1896.

THE inventor forms pulped guncotton, of varying degrees of solubility in a mixture of ether and alcohol, into sheets of paper which, after having been treated by the solvent, will adhere when pressed together, and thus a body of any desired thickness can be built up, which it is claimed will not warp or crack in drying. The density of the explosive can be modified by altering the proportions of the "soluble" and "insoluble" nitrocotton.—W. M.

*Explosives, Impts. in the Preparation of.* L. Roux, Paris, France. Eng. Pat. 4672, Feb. 20, 1897.

THE inventor produces explosives for blasting purposes which he calls "beltermes," by mixing ammonium cresylate with ammonium nitrate in the proportions  $\frac{1}{4}$  to  $\frac{22}{100}$  per cent. of the cresylate to 78 to 95  $\frac{1}{2}$  per cent. of the nitrate. Five per cent. of potassium chlorate dissolved in water is then introduced into the mixture and thoroughly incorporated with it, and after drying, the composition is compressed into cartridges. Another composition consists of a mixture of the ammonium cresylate and nitrate as above, with about 10 per cent. of nitroglycerin containing 1 per cent. of nitro-cotton. Detonators containing 1—1.5 grms. of fulminate should be employed.—W. M.

*Explosives, Impts. in.* O. F. Carlson, Stockholm, Sweden. Eng. Pat. 10,362, April 26, 1897.

THE explosives patented consist of from 40—98 per cent. by weight of ammonium perchlorate, and 60—62 per cent. of inflammable substances such as astatki, naphthalene, paraffin, charcoal, sugar, &c.—W. M.

*Explosive Compound, A New.* W. Majert, Grünau, near Berlin. Eng. Pat. 13,552, June 1, 1897.

THE use of ammonium bichromate is claimed as an explosive agent, the explosion being brought about by a detonator.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Fractional Distillation of Benzine [Petroleum Spirit], New Apparatus for the.* L. Singer. Chem. Rev. Fett-u. Harz-Ind. 4, [8], 108.

THIS apparatus was designed by the author to obviate the disadvantage, inherent in the dephlegmators of Glinsky and Liebel, of the excessive height through which the distilled vapours have to ascend, and which has now, in the present

instance, been reduced to about 20 cm. Platinum gauze is employed to close the bulbs, the glass balls being dispensed with, as formerly used. These balls interfered with the distillation, besides being a source of danger of breakage in transit.—C. S.

*Gas Analysis, Industrial: Apparatus for.* L. Vignon.  
Comptes Rend. 124, 1244—1246.

AN apparatus similar in general construction to that of Orsat, consisting of a measuring vessel with water reservoir, into which the gas can be aspirated, and from which it can be driven into one or more absorption vessels, or into a mercury eudiometer for explosion. Examples are given of the procedure in an analysis, and of the calculations necessary to allow for the volume of the capillary connecting tube.—J. T. D.

*Sealed Glass Tubes, Apparatus for Simultaneously Heating and Shaking in.* E. Fischer. Ber. 30, 1485—1487.

No convenient laboratory apparatus exists for heating and at the same time, agitating substances in sealed glass tubes. The author has described an apparatus which he has used in a research in the urea group, where substances soluble with difficulty, can only be brought to react with oils at a high temperature by continued shaking. The apparatus works so well that the author recommends it for similar purposes.—C. M.

*Fusions, Distillations, and Sublimations: Apparatus for.* L. Paul. Zeits. angew. Chem. 1896, 619.

THE apparatus depicted in the accompanying figure has the advantage over the ordinary porcelain beaker usually

employed in the laboratories of colom factories, &c., in having a handle, by which it is secured, by means of a clamp, in any desired position.—T. A. L.

## INORGANIC CHEMISTRY.— QUANTITATIVE.

*Arsenic, Notes on the Estimation of, in presence in Copper.* G. L. Heath. Eng. and Mining J. 1897, 63, 663.

THE author recommends the following method for the estimation of traces of arsenic:—The precipitate of arsenious sulphide and sulphur obtained in a regular analysis, or by one of the distillation methods, is digested with 20 c.c. of fuming nitric acid until the sulphur is dissolved, and then evaporated with 5 c.c. of pure concentrated sulphuric acid until white fumes are evolved. The liquid is then cooled and diluted with about 2 volumes of water. A Marsh's hydrogen generator is prepared, and 25 grms. of chemically pure zinc (granulated to pass a 20-mesh sieve and be retained by one of 30 meshes to the inch) are placed in the bottle and covered with water to the depth of 1 in. A calcium chloride tube is connected to the bottle and then a piece of combustion tubing ( $\frac{1}{8}$  in. internal diameter and about 2 ft. long). 4 ins. of the tube are maintained at a cherry-red heat during the evolution of gas, and this portion of the tube is surrounded with a double layer of coarse brass or copper gauze to prevent overheating and sagging. The latter portion of the tube is constricted at three or four points, and the evolution of hydrogen, which is started by sulphuric acid (diluted with an equal volume of water and one drop of platonic chloride), is maintained at such a rate that the burning jet of hydrogen at the end is only  $\frac{1}{2}$  in. high. After lighting the jet, the solution to be tested, after mixing with a solution of 0.5

gm. of chemically pure tin in strong hydrochloric acid, is gradually introduced into the generating bottle. The addition of the solution should take about 1½ hours, and the last traces of arseniuretted hydrogen are driven forward by adding dilute sulphuric acid through the funnel, until nearly all the zinc is dissolved. The tube is then cooled, the short portion containing the film of pure arsenic cut off, weighed, and the weighing repeated after dissolving or volatilising the arsenic film.

The author obtained perfectly concordant results by this method for amounts of arsenic less than 6 mgrms., on making check analyses. The addition of tin chloride is important, as in the absence of it, the zinc retains a certain amount of arsenic.—A. S.

*Nitrites, A very Sensitive Reaction for, and Quantitative Estimation of, Colorimetrically.* E. Riegler. Zeits. Anal. Chem. 36, 377—378.

NITRIMOUS acid, proposed as a test for nitrites (this Journal, 1897, 261), is not always procurable of constant quality, and its value as a reagent is thereby impaired.

A reagent is now prepared which is 20 times as sensitive as naphthionic acid, and not subject to this variability.

2 grms. of chemically pure sodium naphthionate and 1 gm. of pure  $\beta$ -naphthol are added to 200 c.c. of distilled water, vigorously shaken, and filtered. The solution is colourless, and may be kept in the dark without change. 10 c.c. of the solution to be tested are placed in a test tube, 10 drops of the naphthol reagent added and 2 drops of concentrated hydrochloric acid, and the mixture well shaken; 20 drops of ammonia are now allowed to flow down the tube, held in a slanting position, when a red ring appears at the junction of the liquids. On shaking, the whole fluid becomes more or less red or rose-coloured, according to the quantity of nitrous acid present. As dilute solutions of the reagent show a violet-blue fluorescence, the colour must be viewed by transmitted light. The reaction is uncommonly sensitive, showing 1 part of nitrous acid in 100 millions. It may be shown in 1 c.c. of rain water or 1 c.c. of saliva. The reaction depends on the conversion of naphthionic acid by nitrous acid into diazonaphthalene sulphonic acid, which forms with  $\beta$ -naphthol and ammonia a red azo dye.

The standard solution for applying the reaction quantitatively is made by dissolving 0.406 gm. of silver nitrite in hot water, adding some sodium chloride, and, when cool, making up to a litre. 100 c.c. of this solution contains 0.0001 gm. of  $N_2O_3$ . 100 c.c. are placed in a flask, 20—30 drops of the reagent added and 4 drops of concentrated hydrochloric acid. It is then repeatedly shaken, and 20 drops of ammonia run in. On shaking, the mixture becomes rose-red in colour, and serves for comparison with the solution to be tested. It must be freshly prepared for each determination.

By this method 0.00005 gm. of  $N_2O_3$  in 1 litre of water may be estimated.

The reagent may be also prepared in the solid form by mixing equal parts of naphthionic acid and  $\beta$ -naphthol intimately in a mortar. A pinch of the powder will serve instead of the 20 drops of reagent. The powder keeps absolutely unchanged, and is as sensitive as the solution.

—L. J. de W.

*Aluminium Utensils, Analysis of.* M. Baland. Comptes Rend. 1897, 124, 1243—1245.

THE author has devised a simple method for the purpose of the examination of the vessels supplied to the French army, the processes already described being considered too long for the purpose (see this Journal, 1896, 136, 839). The aluminium vessels should contain 99—99.5 per cent. of the metal, and those composed of the copper alloy, 2—3 per cent. of copper.

“Pure” Aluminium.—0.5 gm. of the metal cut into thin strips is subjected to the action of 50 c.c. of water and 10 c.c. of pure hydrochloric acid. When the action slackens, the disk is gently warmed until all evolution of gas has ceased. Under these circumstances, carbon, silicon, and copper are unattacked: they are filtered off, washed, ignited, and weighed. To half of the filtrate, 10 per cent. potash is

added in quantity, and the mixture warmed for half an hour; the precipitate is redissolved on the filter by dilute hydrochloric acid, and the solution again treated with potash; the ferric hydrate is now filtered off, washed, ignited, and weighed. In the second half of the filtrate, aluminium and iron are precipitated together by ammonia.

**Copper Alloy.**—Two quantities of 0.5 grm. are separately attacked by 5 c.c. of hydrochloric acid and 50 c.c. of water, the end of the reaction being accelerated by warming. The copper is filtered off from one solution, ignited, and weighed. In the filtrate, iron and aluminium are determined as before. The copper in the second dish is dissolved by adding 25–30 drops of nitric acid. The residue now contains carbon and silicon; this may be filtered off, ignited, and weighed.

—A. C. W.

**Tin in Tin-Plate, Estimation of.** H. Mastbaum.  
Zeits. angew. Chem. 1897, 329.

THE process suggested by Lunge and Marmier (this Journal, 1895, 822) has several disadvantages, involving, as it does, complicated apparatus, and requiring great care during the heating. The following method is preferable:—25 grms. (or even 100, if a fair sample cannot easily be obtained) of the material are boiled for five minutes with 50 c.c. of 10 per cent. hydrochloric acid, and the liquid poured off into a 250 c.c. flask; the operation being repeated with fresh acid two to four times, until the iron is seen to be completely stripped. The solution does not need filtering, but is at once made up to the mark, and 50 c.c. treated with ammonia in a 100 c.c. flask till stannous hydrate begins to fall, when 10 c.c. of yellow ammonium sulphide are added, the whole shaken, filled up, and filtered. 50 c.c. of the filtrate are diluted with water, all the tin sulphide thrown down by acetic acid, and, after standing over night, the precipitate is brought on to a filter by the aid of 10 per cent. ammonium acetate. As, owing to the certain absence of copper, ammonium instead of potassium sulphide is employed, the washing need only be very slight; in fact, 50 c.c. of the sulphide solution can be directly evaporated and ignited in a porcelain crucible, but the former method is preferable. The precipitate is finally heated with fragments of ammonium carbonate until the ash is white. The results quoted by the author are satisfactory; and he notes that the percentage of tin in tin-plate usually lies between 1.94 and 3.07.—F. H. L.

**ORGANIC CHEMISTRY.—QUALITATIVE.**

**$\alpha$ - and  $\beta$ -Naphthol, A Reaction to distinguish between.**  
E. Léger. Bull. Soc. Chim. 17, [11], 546–547.

A SATURATED solution of the naphthol to be tested is made by rubbing in a mortar with water for some time and filtering. To 10 c.c. of this solution are added a couple of drops of a sodium hypobromite solution, made by diluting 30 c.c. of sodium hydroxide solution of sp. gr. 1.33 with 100 c.c. of water and adding 5 c.c. of bromine. With  $\alpha$ -naphthol a violet colour is struck or even a precipitate formed, while with  $\beta$ -naphthol a yellow tint is first seen, which becomes greenish, “dead-leaf coloured,” and finally yellow again. The reaction with the  $\alpha$ -compound is very much more delicate than that with the other, so that by diluting the solution of  $\beta$ -naphthol before applying the test, one can detect in a sample even 1 per cent. of the  $\alpha$ -compound. The naphthol solutions, as well as the hypobromite, must be freshly prepared.—J. T. D.

**Aldehydes and Ketones, Colour Reactions of.** Béla von Bittó. Zeits. Anal. Chem. 36, 369–376.

ALDEHYDES and ketones give colour reactions with salts of meta-diamines. A 0.5 to 1.0 per cent. aqueous or alcoholic solution of a chloride of meta-diamine is prepared, and a few c.c. of the solution are poured into an aqueous or alcoholic solution of the substance to be tested. The alcohol must be free from aldehyde and ketone. In a few minutes the reaction takes place with an intense greenish fluorescence, and reaches its maximum intensity in two hours. The colour disappears on adding alkali, is restored on acidifying, but is enfeebled by mineral acids. The

reaction occurs if the formyl or carbonyl group is not united to a completely substituted hydrocarbon group.

The author also examined Schiff's fuchsin sulphurous acid reaction, and obtained results differing in many particulars from those of other observers. He also finds that the reagent alone always shows a distinct bluish-violet coloration on cooling after being boiled, so that it is not conclusive of the presence of an aldehyde or ketone if a faint colour appears after boiling. Grape-sugar gives no reaction.—L. J. de W.

**Tea, A New Adulterant of.** [Detection.] J. Delaite and H. Lonay. Bull. Assoc. Belge des Chim. 11, [1], 13–21.

THE sample of (green) tea examined was found to contain 68 per cent. of extraneous leaves rolled into a globular shape. On steeping in water these unrolled less readily than the true tea. A bluish-grey powder separated from the leaves under water, and was found to contain manganese in addition to ordinary ash constituents, but no copper or lead. The microscopic examination of the powder led to the conclusion that earth and indigo had been used to imitate the colour of pure tea. In general form the extraneous leaves resembled *Thea chinensis*, but differed therefrom in microscopic character, as also from *Epilobium*, *Jacquinum arctostaphylos*, and other known vegetable adulterants, and, in fact, could not be botanically identified. The authors, however, consider that it is sufficient in practice for the chemist to detect the presence of extraneous adulterant leaves in tea, without specifying their nature.—C. S.

**Sausages, Detection of Artificial Colour in.** H. Bremer. Forschungs-Ber. 1897, 4, [2], 45–48.

CASES have frequently occurred in the author's experience in which artificial colouring matter could be detected microscopically in the fibres, but could not be extracted by any of the usual solvents, such as alcohol, amyl alcohol, or a mixture of glycerin and alcohol. In such cases a mixture of equal parts of glycerin and water, as recommended by Klinger and Bujard, is the best solvent. The finely divided sausage is heated on the water-bath for several hours with two volumes of this mixture (slightly acidified), the yellow-coloured liquid freed from fat and filtered, and the colouring matter precipitated as lake by the addition of alum and ammonia. On placing the test tube before the spectroscope, the absorption lines of carmine lake, lying between *b* and *D*, may easily be identified. Since carmine lake gives a red solution with hydrochloric, nitric, and tartaric acids, whilst the acid solution of the sausage colouring matter is yellow, it is suggested that the carmine is present in some other form than lake, possibly combining with the preserving agent to form a compound insoluble in alcohol.—C. A. M.

**Cheese, Detection of Margarin in.** H. Bremer. Forschungs-Ber. 1897, 4, [3], 51–53.

THE old method of extracting the fat from cheese with ether is, in the author's opinion, open to the objection that impurities are simultaneously extracted. By Hensold's process, in which the fat is extracted by shaking the cheese with 5 per cent. potash, all the free fatty acids, as well as those in combination with the ammonia, are saponified. The method recommended as the most satisfactory is to shake the finely divided cheese with water at 20°–30°, preferably acidified with sulphuric acid (5:200), and to apply centrifugal force, when the fat rises to the surface, whilst the albuminoid substances coagulate at the bottom. In addition to the determination of the usual constants, valuable information may be obtained from the iodine number of the liquid fatty acids separated by the process described by the author (this Journal, 1897, 641). In a number of experiments with pure butter fat, the iodine value of the liquid fatty acids did not exceed 95, even when the cows had been fed on maize oil-cake. A sample of Edamur cheese, when thus examined, yielded a fat the liquid acids of which had an iodine value of 93.35, whilst the values obtained with two samples of margarin cheese (Rodamur and Backstein) were 110.3 and 109.0 respectively.

—C. A. M.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Paraffin in Lignite-Tar Products, Estimation of.* H. Eisenlohr. *Zeits. angew. Chem.* 1897, 300 and 333.

This paper consists of a detailed examination into the processes devised by Zulozicki and Holand for the determination of paraffin in lignite-tar oils; Holde's method not being dealt with, as it is designed simply for petroleum products which give a residue insoluble in alcohol. As the result of a large number of experiments, which he records at length, the author concludes that all the methods which have hitherto been published are but moderately accurate even when only paraffins of a high melting point have to be determined; where, however, softer paraffins are in question, they become valueless, for the following reasons. — (1) The temperatures (100° or 125° C.) at which it is usually recommended to dry the products are too high, and cause considerable loss by volatilisation; for instance, a paraffin melting at 29.5° may lose 10 per cent., and one melting at 38°, 1.4 per cent. at 100° C.; while at 125°, a 33° paraffin will lose 18.5, and a 48° sample 1.8 per cent. Moreover, the exact amount of these losses is entirely dependent on the time of heating, and also on the size and shape of the vessel containing the paraffin. (2) The solubility of the lower paraffins in ethyl alcohol is greater than that stated by Holand (this Journal, 1894, 286); for both Holde and the present author agree that 100 c.c. of 99.5 per cent. spirit dissolve 0.03 grm. of a specimen melting at 55°–56°. Since lignite tar contains paraffins of a far lower melting point, and since their solubility in alcohol rises as their melting point falls, it is clear that 0 C. is not sufficiently low for the working temperature.

Eisenlohr finds that all the lignite-tar paraffins melting between 31.5° and 60° C. which do not contain more than 14 per cent. of oil, may be accurately estimated by the use of ethyl alcohol of 80° Tr., provided the operation is carried out in the manner indicated. About 0.5 grm. of the substance is dissolved in 100 c.c. of absolute ethylic alcohol, 25 c.c. of water added, and the whole cooled to –18° or –20° by means of a freezing mixture. After a short time it is thrown on a paper (tared under precisely the conditions afterwards adopted in drying the paraffin), which is placed in a filtering apparatus, such as that described by Holde (this Journal, 1897, 362, Fig. 1), but connected with a pump. The precipitate is washed with alcohol of 80° Tr., previously cooled to –18°, until the filtrate is no longer rendered turbid by additions of water, then put into an exhausted desiccator containing sulphuric acid, and heated to 35° or 40° C. for 6 or 8 hours, till its weight remains constant.

Treated in this way, one sample of a pure paraffin melting at 31.5° C., after being mixed with 6.19 per cent. of a paraffin-free oil, gave 93.49 per cent. of true paraffin.

—F. H. L.

*Asphalt, Testing Artificial.* M. Gary. *Mitt. k. Versuchsanst. zu Berlin*, 15, [1], 74–80.

The samples examined were made by Zoeller, Wolfers, and Dröge, of Berlin, from coal-tar melted along with 2 to 3 per cent. of sulphur and mixed with about 2.5 per cent. of fine, sifted bleaching powder, the whole being then incorporated by heating and stirring with granulated and ground blast-furnace slag, and finally compressed, under 200 atmos. pressure, into blocks 25 by 12.5 by 5 cm. For the sake of comparison, the samples (A) were tested side by side with similar samples (B) prepared in a knee-lever press and with blocks (C) of Sicilian natural asphalt.

In testing the (heat) conductivity of the sample A, a hole was bored in the longest side, as far as the centre, and filled with mercury in which a thermometer was immersed, and the block heated in a drying oven. At the end of four hours, the temperature of the oven being 71° C., that of the block registered 66° C., and that of a block of wood of equal size and under the same conditions, 61° C. With an oven temperature of 66° C. and the same exposure, the temperatures were 57° C. and 55° C. respectively. In point of radiation on cooling, observed at a room temperature of 17° C., both asphalt and wood cooled about 1° C. in five minutes, about 5° C. in 10, and 10° C. in 20 minutes.

For testing the resistance to pressure at high and low temperatures, such as would prevail in practice (street paving), the blocks were sawn in half and heated in an air chamber immersed in a water-bath over a sand-bath, the temperatures being regulated to 80° C., 40° C., and 18° C., respectively. The blocks were embedded in wooden frames to prevent radiation of heat on all sides except the face, which was exposed to the air of the chamber. For the cold test they were kept in a cold chamber containing a Linde-refrigerating machine producing an air temperature of about –15° C. In all cases the time of exposure was the same, viz., three hours. The blocks were then placed in an Anslar-Lasson press and pressure applied—to a sharp-edged steel cylinder 4.2 cm. in diameter (12.85 sq. cm. section) and 3 cm. high, resting freely on the block—until breaking resulted.

The average results obtained were as follows:—

Temperature.	Pressure, in Kilos. per Sq. Cm., required to produce (1) a Visible Impression, (2) Breakage.					
	Sample A.		Sample B.		Sample C.	
	1.	2.	1.	2.	1.	2.
–15° C. ....	153	391	159	403	53	111
+18° C. ....	15	127	38	67	21	32
+40° C. ....	38	95	22	44	9	19
+80° C. ....	25	54	19	27	9	13

It is therefore evident that whilst in the cold the two samples of artificial asphalt, A and B, differ but little in their ability to stand pressure, A is considerably the better in this respect in the warm, and both far surpass the natural asphalt C.

It is considered that the patented idea that the process should be worked by municipalities, who could supply the chief materials from the by-products of their own gas-works, might be of importance in districts where stone is scarce.

—C. S.

*Indigo Testing.* J. Grossmann. *J. Soc. Dyers and Colourists*, 1897, 124–128. (See also this Journal, 1885, 189 and 491; 1887, 455; 1888, 429; 1889, 610; 1891, 188; 1892, 63; 1893, 67; 1894, 426; 1895, 893; and 1896, 475.)

In reviewing the various methods that have been proposed for the assay of indigo, the author concludes that, apart from all other objections which he raised to specific processes, all those which are based on a standard indigotine are unreliable, inasmuch as no two samples of indigotine are of the same strength or composition, owing to the difficulty of preparing this substance in a pure state. Rawson's hydrosulphite process (this Journal, 1885, 489), gives good results, but "requires concentrated attention" and a somewhat complicated apparatus; whereas his permanganate process, whilst giving fair results with high-class indigos, is not to be relied on in the case of lower qualities. Moreover, the indigo red always affects the tinctorial powers of the indigo, and should be taken into account in estimating the value of the latter.

The author has worked out a process based on comparative dye tests, the indigo being first purified and then converted into its sulphonic acid for the purpose. He has also devised an apparatus for carrying out the process, consisting of a reel A, made of glass or porcelain, arranged in such a way that it can be made to revolve in a beaker B, which is placed in a water-bath C. Several of these little machines may be geared together, as shown, and driven by a water turbine or some other motor.

The test is performed as follows. One grm. of the sample to be tested, ground to a fine powder in an agate mortar and mixed with about five times its weight of ground glass, is placed on a dry filter and washed with hot dilute hydrochloric acid (one part of strong acid to four parts of water), until the filtrate is no longer coloured brown. The filtrate is then made up to a definite volume. The sample is next washed with a hot solution of sodium hydrate

(containing 2 per cent. of  $\text{Na}_2\text{O}$ ), until the washings are no longer brown, and the filtrate is again made up to a definite volume. The contents of the filter are then washed with

hot water to remove the soda, dried in an air-bath at  $100^\circ \text{C}$ . and ground in an agate mortar to a uniformly fine powder. This powder is then transferred in small portions at a time to a porcelain crucible containing 25 c.c. of pure sulphuric acid (sp. gr. 1.85), stirring well with a glass rod after each addition, and is heated for  $1\frac{1}{2}$  hours in an air-bath at  $95-100^\circ \text{C}$ ., the contents being stirred from time to time. When cold, the mixture is washed into a litre flask, filled up with water to the mark, and filtered.

Five grms. of woollen yarn are now wound on to the reel of the dyeing machine, the beaker is filled with water until the latter just covers the top of the reel, and 1 c.c. of ammonia of sp. gr. 0.880, is added to the same. In this dilute ammonia solution, the yarn is scoured for half an hour at  $100^\circ \text{C}$ ., the reels being kept revolving. After rinsing, the vessel is again filled with clean water, and 2 c.c. of a 10 per cent. solution of aluminium sulphate and 10 c.c. of the prepared indigo solution are added to the bath. The wool is kept revolving in this until the bath is nearly exhausted (about  $1\frac{1}{2}$  hours), taken out, rinsed, and dried. The exhausted bath is kept for reference, and compared with the exhausts of previous and subsequent dye tests.

In testing several samples of different values, quantities representing equal money's worth are taken, in which case the sample giving the fullest shade would be the cheapest.

—I. S.

*Low Iodine Number of Linseed Cake, Cause of the.* G. Fassbender and J. Kern. *Zeits. angew. Chem.* 1897, 331.

The authors find that by cold pressure, a pure linseed oil may be obtained even from adulterated seed, as the resulting cake retains the greater part of the oil derived from the foreign *Crucifera* present. It is impossible, therefore, from a mere determination of the iodine number of the pressed cake, to calculate the amount of impurity existing in the original linseed.—F. H. L.

*Beeswax, The Iodine Value of.* R. Glode Guyer. *Pharm. J.* 1897, 58, 308.

From a number of experiments with genuine English beeswax, the author concludes that the iodine absorption number, obtained in the ordinary manner with Hübl's solution, is a useful factor in the analysis of yellow wax; but is of no service in the case of white wax.

Finding that various authorities differed as to the limits of this figure for pure wax, a number of determinations were made, which point to a mean of 8.5 as the true iodine absorption number, and indicate that the standard should be from 8 to 9, and not a higher figure as stated by others. The test is useless with white wax, since the process of bleaching almost wholly removes, or modifies, the iodine absorbing bodies.—J. O. B.

*Linseed Oil [for Varnish-making], Valuation of.* W. Lippert. *Zeits. angew. Chem.* 1897, 306.

The author protests against Amsel's statement (this *Journal*, 1895, 605), that rosin itself as well as rosin oil and mineral oil can be detected in linseed oil by determination of the saponification number, and by the alcoholic soap solution becoming turbid on dilution with water. It frequently happens that aqueous solutions of pure linseed soaps show a faint opalescence, and, on the contrary, that such liquids even when containing a large excess of rosin, will remain clear for a considerable time; while, moreover, many varieties of colophony which at first give cloudy solutions, after repeated melting, lose this property almost entirely. In a recent pamphlet Amsel says that linseed oil alone should dry on glass in three days, or in 24 hours if 5 per cent. of a drier be added. Apart from the influence of light and temperature on this test, the speed of drying is strictly dependent on the amount of metallic drier employed; the experiment, therefore, must only be carried out in the presence of a definite quantity of a drier of known composition. Amsel's figures also tend to prove that a varnish containing 1 per cent. of a manganese resinate dries more quickly than if it contains 3 per cent., or if it has been boiled with 3 per cent. of red lead; but this appears to be a mistake, and the small proportion of rosin that exists in these products certainly does not hinder their desiccation.

Lippert holds that an oil suitable for the varnish maker must give a good drying test, must bear heating to  $300^\circ \text{C}$ . without the formation of any flocculent deposit—remaining perfectly clear—must yield the correct saponification number, as well as a transparent, or only faintly opalescent, solution on diluting the soap with water, and must be tested separately for rosin according to the ordinary methods.—F. H. L.

*Sugar Products, Estimation of Lime in, by Soap Solution.* H. Pellet and O. Castels. *Bull. Assoc. Chim.* 14, [11], 1190—1193.

The use of soap solution in testing for lime salts in products of sugar works appears to give good results, in agreement with those obtained directly by ammonium oxalate, within 10 per cent. more or less. Certain cane-sugar juices, however, which gave no precipitate with ammonium oxalate, showed with soap solution the presence of an alkali combining with soap, which was not lime, and other cases gave great differences in the results obtained by the two methods. This was found to be due to the presence of magnesia derived from the lime used. It is therefore necessary to check each series of tests by a determination with ammonium oxalate and, if necessary, to use a factor for reducing the results. It is also necessary to see if the coefficient to be applied is the same for juices and syrups, for massecuites where the syrups are not returned as for products more highly charged with salts, as molasses.

There is one peculiarity of certain products which affects the exactitude of the soap test. At a given moment an abundant froth may be noticed which would lead one to suppose the operation was complete, but a few moments later the froth disappears and several tenths of a c.c. more soap solution are required to make the froth persist. It is the latter limit which must be taken.—L. J. de W.

*Sugar Canes, Mode of Sampling and Method of Analysis of.* Report on the Agric. Work in the Botan. Gardens, Brit. Guiana, for the Years 1893—4-5, 1897, 9—10.

See under XVI., page 687.

*Hops, Estimation of Resins in.* L. Briant and C. S. Meacham. *J. Fed. Inst. Brewing*, 1897, 3, 233—236.

To determine the soft resins, about 4 grms. of carefully sampled hops are introduced into a thimble of bibulous

paper or glass, and are placed in an 80 gram. Soxhlet apparatus, and extracted for 24 hours with 120 c.c. of petroleum ether having a boiling point of 122° F. When the extraction is complete, the extract is filtered whilst hot into a tared wide-mouthed flask, the filtrate gently evaporated, and the flask and its contents dried in a water-oven until the weight is constant. The residue left in the extractor that contains the hard resins is now extracted for 12 hours with 120 c.c. of ordinary ether, and the extract passed through the same filter as in the previous operation, the subsequent drying and evaporation being carried out in a similar manner. If necessary, the extracted hops may be dried and weighed. The results are expressed on dry hops; but, for commercial purposes, the moisture should be stated as well as the amount of foreign matters. It has been observed that during the evaporation of the extract containing the soft resins, these change to some extent into hard ones, since their solubility in petroleum ether is considerably reduced.—J. L. B.

*Carbohydrates in Foodstuffs, The Quantitative Determination of.* W. E. Stone. J. Amer. Chem. Soc. 1897, 19, 183—197; 347—349.

In various articles published by the author during the past 10 years, attention has been called to the character of the composition of the so-called "nitrogen-free extract" of food materials. It is generally recognised that the portion of food material comprised under the above head, consists of a considerable number of definite chemical compounds, mostly of the nature of carbohydrates, but of such evident variation as regards their food value or digestibility, as well as their chemical and physical properties, that it is inconsistent to regard them of homogeneous character or value in food estimation.

The author has devised the following method for the detailed determination of the carbohydrates in vegetable materials. In all the operations linen filters should be used in order to facilitate the subsequent removal of the sample. With very fine starchy materials it is sometimes advisable to fold a paper filter within the linen one.

1. From 50 to 100 grams of the sample are boiled with 500 c.c. of strong alcohol under a reflux condenser for two hours, or it may be extracted in a Soxhlet's apparatus. The sugars are thus dissolved, and are removed by filtering off the alcoholic extract. This treatment also dissolves waxes and oils; these, however, may be separated from the sugars by evaporating the solution nearly to dryness, and then taking up with water. If the solution contain only cane sugar it may be brought to a given volume and polarised. If several kinds of sugar be present (say, cane and invert sugar), the alcohol is evaporated, the residue dissolved in a known quantity of water, and the sugars estimated by titration with Fehling's solution before and after inversion, according to the ordinary method of treatment.

2. The residue from the alcoholic extraction may contain carbohydrates soluble in water, as for instance, soluble starch and dextrin, which are specially to be considered in materials which have been subjected to the action of heat.

500 c.c. of water are added to this residue and the whole allowed to stand from 18 to 24 hours, with frequent agitations. The solution is filtered, and in the case of ordinary materials, where only dextrin-like substances are to be expected, evaporated to a small volume, inverted with dilute acid, and titrated with Fehling's solution. If, however, the solution contain soluble starch, which may be recognised by the iodine test, a further distinction between this starch and dextrin is necessary. The aqueous solution is brought to a volume of 200 c.c., and of this an aliquot portion is inverted with dilute acid and the total carbohydrates in solution determined by titration with Fehling's solution. Another aliquot portion may be treated with an excess of barium hydroxide solution, the soluble starch being thereby precipitated. In the filtrate from this precipitate, the dextrin may be determined by inversion and titration as before; the difference between this value and the total carbohydrates being considered as soluble starch. The use of barium hydroxide for the direct estimation of soluble starch according to Von Aschoth's method, is not permissible in this place, because there are other substances in solution, such as the albuminoids, which combine with the alkali.

3. The residue from the aqueous extract of the material is now brought to an air-dried condition, and weighed, in order to establish its quantitative relation to the sample as originally weighed out. 2 grams of this material, which now contains the starch and other insoluble carbohydrates, are weighed and boiled for 20 minutes with 100 c.c. of water, in order to convert the starch into a soluble form. When the solution has cooled to 60°, 10 c.c. of malt extract (10 grams of malt to 50 c.c. of water) are added, and the conversion allowed to proceed at 65° for two to three hours, after which it is filtered and the filter washed with hot water. The residue on the filter should give no iodine reaction. The filtrate is evaporated to 100 c.c., 10 c.c. of strong hydrochloric acid added, and inverted for one hour in a boiling water-bath. The solution is neutralised, and titrated with Fehling's solution, a correction being made for the amount of sugar contained in the added malt extract.

4. The residue from the last process contains the gums, pentosans, hemicelluloses, and cellulose. It is carefully removed from the filter, 100 c.c. of water and 2 c.c. of strong hydrochloric acid added, and boiled under a reflux condenser or in a water-bath for one hour. This treatment converts the gum and pentosans into reducing sugars (xylose). The solution is filtered, neutralised, made up to 200 c.c. and titrated with Fehling's solution.

5. The residue is treated with a 1.25 per cent. solution of sodium hydroxide, filtered, dried, weighed, ignited, and weighed again in order to obtain what is commonly known as crude fibre.

Following this scheme of analysis, the author has tabulated the results obtained with some representative food-stuffs.

In the second paper, attention is drawn to some uncorrected errors in the determination of normal starch. The corrected table is given below:—

	Cane Sugar.	Invert Sugar.	Dextrin.	Soluble Starch.	Normal Starch.	Pentosans.	Crude Fibre.	Total Carbohy- drates.	Nitrogen-free Extract.
Wheat I. ....	0.52	0.08	0.27	0.00	57.62	4.54	2.68	65.71	77.07
Wheat II. ....	0.72	0.00	0.41	0.00	55.27	4.37	2.51	64.28	77.66
Flour I. ....	0.18	0.00	0.90	0.00	67.69	0.00	0.25	69.32	83.54
Flour II. ....	0.20	0.00	1.06	0.00	67.76	0.00	0.25	69.27	84.54
Maize ....	0.27	0.00	0.32	0.00	65.45	5.14	1.39	73.17	78.02
Bread (Wheat I.) ....	0.11	0.10	0.68	1.37	53.24	4.16	2.70	62.59	77.20
Bread (Wheat II.) ....	0.05	0.32	0.23	2.36	58.62	4.34	2.12	63.34	77.33
Bread (Flour I.) ....	0.06	0.37	0.27	1.39	64.81	0.00	0.34	67.84	82.94
Bread (Flour II.) ....	0.15	0.38	0.91	1.74	64.12	0.00	0.17	67.47	85.17
Corn bread (Maize) ....	0.16	0.19	0.00	2.80	61.74	3.54	2.22	70.75	77.81

The discrepancy existing between the total carbohydrates and nitrogen-free extract may arise from one of two sources of error in the determination of carbohydrates, or the existence of a substance free from nitrogen and which is of a character not usually ascribed to carbohydrates and resistant to the ordinary reactions for such. While the first

alternative is not excluded, the author is inclined to the latter conclusion.—J. L. B.

*Wheat, The Insoluble Carbohydrates of.* H. C. Sherman. J. Amer. Chem. Soc. 1897, 19, 291.

See under XVI., page 690.

*Cacao-Butter, Iodine Number of.* D. Holde. *Zeits. Anal. Chem.* **36**, 381.

HOLDE pointed out (this Journal, 1897, 363) that the upper limit of the iodine number for cacao-butter given by de Negri and Fabris as 51, was incorrectly transcribed from von Hubl's original work, where it is given as 34.

The error is now admitted by Fabris, the number having been copied unnoticed from the 1896 edition of Benedikt's "*Analyse der Fette und Wachsarten*." The new edition of this work, in which it is given correctly, was not available when de Negri and Fabris published their monograph "*Gli Olii*."—L. J. de W.

*Acid Potassium Tartrate (Cream of Tartar) in Wine, Determination of.* H. Jay. *Bull. Soc. Chim.* 1897, **17**, 626—629.

AN examination of the methods employed for the determination of acid potassium tartrate (cream of tartar) in wine. The following table gives the weights of acid tartrate found by the methods under investigation:—

Solution employed.	Precipitation by Ether-Alcohol.	Crystallisation after Evapora- tion to $\frac{1}{10}$ .
	Grms.	Grms.
1. Alcohol of 95 + 1.35 grms. of tartar.	1.13	1.24
2. Alcohol of 95 + 2.72 grms. of tartar.	2.53	2.60
3. Wine .....	2.10	2.55
4. Same wine + 1 grm. of tartar..	3.12	3.12
5. Perry .....	Trace	0.30
6. Same perry + 3 grms. of tartar	2.82	3.24
7. Same perry + 3 grms. of tartar + potash to neutralise 1.375 grms. of tartar.	2.82	3.12
8. Synthetic wine containing 3 grms.	2.86	3.36
9. Synthetic wine containing 1 grm.	0.83	1.21

The higher results given by the crystallisation method are not entirely due to the smaller loss in that method: the correction deduced from experiments 1 and 2 does not explain the results of experiments 4, 6, 8, and 9. The excess found by this method is due to the crystallisation of another acid salt—the malate—along with the tartrate. It is the malic acid which is neutralised in experiment 7. The author concludes that the results of the precipitation method are more exact, and, with the corrections, more constantly near the truth than those of the crystallisation process. The evaporation in this last appears to destroy the equilibrium existing between acids and bases.—A. C. W.

*Ether, Method for the Determination of Aldehyde in.* Maurice François. *J. Pharm. Chim.* 1897, **5**, 521—525.

AS application of the method of Mohler for the determination of aldehyde in alcohol (this Journal, 1897, 265). The reagent contains 220 c.c. of saturated sulphur dioxide solution, 30 c.c. of 0.1 per cent. magenta solution, and 3 c.c. of sulphuric acid of 66°. Solutions of aldehyde in alcohol containing 1 in 1,000 and 1 in 10,000 are employed for comparison.

5 c.c. of each solution and of the ether to be tested, are mixed with 5 c.c. of alcohol in test tubes, 1 c.c. of the reagent are added to each of the three tubes; these are shaken, corked, and the colour observed after 15 minutes. This preliminary trial shows which standard solution must be employed in the colorimeter. Ether free from aldehyde is obtained by treatment of 1 kilo. of ordinary ether with 200 c.c. of saturated permanganate solution and 20 grms. of caustic soda. After standing 24 hours, with frequent shaking, the treatment is repeated, the ether filtered, and dried over a mixture of 50 grms. of quicklime and 50 grms. of calcium chloride; it is then filtered and distilled.

—A. C. W.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Strontium Sulphide, Phosphorescence of.* J. R. Mourelou. *Comptes Rend.* **124**, [22], 1237—1238.

PURE strontium sulphide, obtained by reducing the sulphate with carbon, by treating the carbonate at a red heat with hydrogen sulphide, or by heating the carbonate with sulphur, is *not phosphorescent*. If any one of these sulphides, however, be heated for some time in an oxidising flame, so as to form a small amount of sulphate, it becomes phosphorescent.

After prolonged heating in an oxidising atmosphere, so as to convert the greater part of the sulphide into sulphate, the phosphorescence is lost, but is recovered again on reduction by charcoal, if that reduction has left even as much as 0.042 per cent. of sulphate. Strontium sulphide prepared by the author's method, when it is obtained as a hard, granular, semi-polished substance, not at all easily changed in moist air, but still containing a trace of sulphate, exhibits very strong phosphorescence. Both an oxidising substance and a certain structure, then, appear to be influential in determining the phosphorescent power of strontium sulphide.—J. T. D.

*Calcium Carbide Residues, Use of, as Antidote to Phylloxera.* E. Chuard. *Comptes Rend.* **124**, 1247—1248.

IN a previous note, the author has shown that among the products of decomposition of calcium carbide by water are small amounts of ammonia, which come off in greater quantity after the whole of the acetylene has been evolved, than before. The residues from acetylene preparation are thus valuable as a fertiliser, and they also serve as an insecticide. Attempts have been made in Spain, and lately by the author at Veyrier (Haute-Savoie), to treat vines with these residues for phylloxera, with considerable success. The toxic properties seem to be due in part to the presence of traces of phosphine in the evolved gas, and experiments made by the author with a specially prepared carbide containing a notable amount of phosphide (not enough to render the evolved gas spontaneously inflammable), have been very successful, the substance having proved a very powerful insecticide, while as a destroyer of phylloxera it seems also, as far as the experiments have yet gone, very hopeful.—J. T. D.

*Metallic Salts, New Combinations of, with Pyridine, Piperidine, and Quinoline.* R. Varet. *Comptes Rend.* **124**, [21], 1155.

*Pyridine Bromocuprite.*—Pure cuprous bromide is dissolved in boiling pyridine to saturation, avoiding all access of air. The solution is filtered through a hot-water funnel, and forms, on cooling, a crop of green crystals. These, when dried rapidly between filter papers, have the composition  $\text{Cu}_2\text{Br}_2(\text{C}_5\text{H}_5\text{N})_3$ . This body is very soluble in pyridine, especially when warmed. When heated, all the pyridine is given off. It is very unstable in the air, turning first green, then brown.

*Pyridine Iodozincate.*—Zinc iodide combines with pyridine with the evolution of a considerable amount of heat. The compound  $\text{ZnI}_2(\text{C}_5\text{H}_5\text{N})_2$  occurs in fine needles.

*Pyridine Cyanozincate.*—Cyanide of zinc is not appreciably soluble in pyridine. If the two bodies are left in contact in the dark in a cool place, a gelatinous mass is obtained of uncertain composition. This body parts with all its pyridine on warming, at a much lower temperature than that at which the cyanide decomposes.

The author has also prepared combinations of pyridine, of piperidine, and of quinoline with the halogen salts of aluminium and iron; also with the iodides of barium, strontium, and calcium, and with the bromides and iodides of manganese. The action of piperidine on the chlorides, iodides, and bromides of zinc, cadmium, nickel, and cobalt has also been studied. Quinoline has also been combined with the salts of mercury, of silver, and of copper.—J. O. B.

*Moisture by Deliquescent Substances, Further Experiments on the Absorption of.* H. Wilson Blake. *Prec. Chem. Soc.* 1897, [182], 147.

In a preliminary note (Proc. Chem. Soc. 1896, 12, 33) the author showed that certain deliquescent salts, when exposed to the air, attained a maximum of hydration, and that its maximum corresponded to a definite number of molecules in a large number of cases.

In the preliminary experiments no reference was made to the vapour pressure of water in the air, but in experiments since made, the condition of the atmosphere as regards moisture has been carefully noted, or an artificially saturated atmosphere has been contrived under known conditions of temperature.

Having now experimented with 10 deliquescent chlorides (lithium, magnesium, cadmium, calcium, copper, nickel, cobalt, iron, manganese, and platinum), three nitrates (sodium, magnesium, and manganese), with sulphuric acid and with sodium formate, under various conditions, it was found that (1) they attract quantities of water corresponding in all cases to a definite hydrate, (2) after deliquescenting to a maximum, there followed in all cases a decline in weight, and in four instances the salts returned to their original hydration and crystallised out, and that (3) the amount of hydration, though apparently always corresponding to a definite number of molecules of water, is not always the same, but seems to depend, within certain limits, both on the temperature and the relative humidity of the atmosphere and also on the conditions under which the air has access to the salt.

The author suggests that the above experiments demonstrate that the phenomenon of deliquescence is caused by hydration of the deliquescent salt.

"Mineral Soap." W. C. Knight. Eng. and Mining J. 1897, 63, 600.

"Mineral soap" is the name given to a peculiar kind of clay found in various parts of Wyoming, U.S.A. The clay, when taken from the quarry, has a greenish-yellow colour, which, on exposure to the air, soon changes to a light cream. It forms an emulsion with water, but only a very small percentage dissolves. Thin seams of gypsum and mirabilite (a hydrated sodium sulphate) are found associated with the clay. The following analysis of one of these clays from Rock Creek, Albany Co., Wyoming, is given:—

$\text{SiO}_2$ , 59.78;  $\text{Al}_2\text{O}_3$ , 15.10;  $\text{Fe}_2\text{O}_3$ , 2.40;  $\text{MgO}$ , 4.14;  $\text{CaO}$ , 0.73;  $\text{H}_2\text{O}$ , 16.26 per cent.—A. S.

#### Etherification, Study of the Ordinary Process of.

L. Prunier. Comptes Rend. 124, [22], 1239—1242.

The theory of Williamson, based on the successive formation of ethylsulphuric acid and its reaction on alcohol to form ether and regenerate the sulphuric acid originally present, cannot represent the whole truth, for the process does not continue indefinitely, and can go on without the presence of free sulphuric acid.

Possibly the successive reactions—

partly explain it, but the existence of sulphonic compounds among the products of the process, already demonstrated by the author, enables a much more complete account to be given. Isethionic acid (as a type of these compounds) may be formed by the splitting up of the ethylsulphuric acid

and the immediate action of the trioxide and the alcohol

The ethyl ether of this is then successively formed and decomposed exactly as in the equations given above for ethylsulphuric acid. This view is borne out by the fact that according to Krafft the sulphuric acid of the ordinary etherification process may be substituted by benzenesulphonic acid. It also accounts for the gradual loss of sulphuric acid, which is partly separated and hydrated by the action of the water formed on the ethylsulphuric acid, partly escapes as sulphur dioxide through the dissociation of some of the sulphonic compounds.—J. T. D.

## New Books.

THE PROSPECTOR'S HANDBOOK. A Guide for the Prospector and Traveller in search of Metal-bearing or other Valuable Minerals. By J. W. ANDERSON, M.A., F.R.G.S. Seventh Edition, thoroughly revised and much enlarged. Crosby, Lockwood, and Son, 7, Stationers' Hall Court, Ludgate Hill, London, E.C. Price 3s. 6d. In strong leather wallet with tuck, price 4s. 6d.

This small volume, with rounded corners for convenience of the pocket, contains prefaces to the first and seventh editions, table of contents, and 152 pages of subject-matter. Thereafter follow a glossary of terms used in connection with Prospecting, Mining, Mineralogy, Assaying, &c., and the alphabetical index. The text, which is illustrated with 69 woodcuts, is subdivided as follows:—I. Prospecting. II. Rocks. III. Testing Minerals by the Blow-pipe. IV. Character of Minerals. V. Metals and Metallic Ores: their Characteristics, Testing, Occurrence, &c. VI. Other Useful Minerals and Ores. VII. Composition of Various Rocks. VIII. Testing by the Wet Process. IX. Assay of Gold. X. Treatment of Ores. XI. Surveying. Appendix, with Weights and Measures of England, France, &c. Specific Gravities of Various Rocks and Metallic Ores, &c., &c.

ORGANIC CHEMICAL MANIPULATION. By J. T. HEWITT, M.A., D.Sc., Ph.D., Professor of Chemistry in the East London Technical College. Whitaker and Co., 2, White Hart Street, Paternoster Square, London, E.C. 4, 66, Fifth Avenue, New York, U.S.A. 1897. Price 7s. 6d.

Small 8vo volume with preface, table of contents, subject-matter filling 253 pages, illustrated with 63 woodcuts, and terminating in an alphabetical index.

The design of the work will appear in the following brief excerpt of its contents:—

PART I.—I. Purification of Organic Substances. II. Ultimate Analysis of Organic Compounds. III. Determination of Equivalent and Molecular Weight. IV. Estimation of Specific Groups of Atoms in Organic Compounds.

PART II.—V. Compounds of the Fatty Series. VI. Aromatic Hydrocarbons and their Derivatives. (i.) Hydrocarbons and their Nitration. (ii.) Reduction of Nitro-compounds. (iii.) Diazo-compounds and Hydrazines. (iv.) Sulphonation. (v.) Phenols. (vi.) Aromatic Acids. (vii.) Aromatic Aldehydes and Ketones. (viii.) Quinones. (ix.) Condensations resulting in the Formation of Closed Ring Compounds.

A COURSE OF PRACTICAL CHEMISTRY. By M. M. PATTERSON MURK, M.A., Fellow and Practitioner in Chemistry of Gonville and Caius College, Cambridge. PART I. ELEMENTARY. Experiments on Chemical Change. Preparations of Various Compounds. Reactions of Acids, Alkalis, and Salts. An Elementary Course of Volumetric Analysis. Qualitative Analysis of Mixtures of Salts containing not more than a single metal in any one group. Longmans, Green, and Co., 39, Paternoster Row, London; also New York and Bombay. 1897. Price 4s. 6d.

This book is intended for use in connection with lectures and demonstrations. It forms Part I. of a work which is to be complete in three parts. It contains subject-matter filling 301 pages, illustrated with 33 woodcuts, and followed by five appendices and an alphabetical index.

The work (Part I.) is divided into three sections:—

SECTION I. Experiments on Chemical Change. Preparations of Various Compounds. Reactions of Acids, Alkalis, and Salts.

SECTION II. Volumetric Estimation of Acids, Alkalis, Alkaline Carbonates, and Iodine: the necessary standard solutions being given.

SECTION III. Qualitative Analysis. There are five Appendices: I. Making Apparatus. II. Tables. III. Reagents. IV. Preparation of Standard Solutions. V. Substances suitable for the Various Exercises.

## Trade Report.

## TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

## NEW CUSTOMS TARIFF OF CANADA.

With reference to the note on p. 573 of the June number of the Journal, the following are Schedules A, B, C, of the New Customs Tariff of Canada, therein referred to, which received the Royal assent on June 20 last:—

## SCHEDULE A.

## Goods subject to Duties.—Ales, Beers, Wines, and Liqueurs.

No.	Article.	Rate of Duty.
		Dols. Cts.
1	Ale, beer, and porter, when imported in casks or otherwise than in bottle.	Per gall. 0 16
2	Ale, beer, and porter, when imported in bottles (6 quart or 12 pint bottles to be held to contain 1 gallon).	" 0 24
3	Cider, not clarified or refined.	" 0 5
4	Cider, clarified or refined.	" 0 10
5	Lime juice and fruit juices, fortified with and containing not more than 25 per cent. of proof spirits.	" 0 60
	Do., when containing more than 25 per cent. of proof spirits.	" 2 00
6	Lime juice and other fruit syrups and fruit juices, n.o.p.	20 % ad val.
7	Spirituos or alcoholic liquors distilled from any material, or containing or compounded from or with distilled spirits of any kind, and any mixture thereof with water for every gallon thereof of the strength of pr of and when of a greater strength than that of proof, at the same rate on the increased quantity that there would be if the liquors were reduced to the strength of proof. When the liquors are of a less strength than that of proof, the duty shall be at a rate herein provided, but computed on a reduced quantity of the liquors in proportion to the lesser degree of strength; provided, however, that no reduction in quantity shall be computed or made on any liquors below the strength of 15 per cent. under proof, but all such liquors shall be computed as of the strength of 15 per cent. under proof, as follows:—	Per gall. 2 40
	(a.) Ethyl alcohol, or the substance commonly known as alcohol, hydrated oxide of ethyl or spirits of wine, gin of all kinds, n.e.s., rum, whiskey, and all spirituos or alcoholic liquors, n.o.p.; amyl alcohol or fusel oil, or any substance known as potato spirit or potato oil; methyl alcohol, wood alcohol, wood naphtha, pyroxylic spirit or any substance known as wood spirit or methylated spirits, absinthe, arracker palm spirit, brandy, including artificial brandy and imitations of brandy, cordials and liqueurs of all kinds, n.e.s.; mescal, pulque, rum, shrab, schiedam, and other schnapps; tafia, angostura and similar alcoholic bitters or beverages.	Per gall. 2 40
	(b.) Spirits and strong waters of any kind, mixed with any ingredient or ingredients, as being or known or designated as anodynes, elixirs, essences, extracts, lotions, tinctures, or medicines, or medicinal wines (so called), or ethereal and spirituos fruit essences, n.e.s.	30 % ad val.
	(c.) Alcoholic perfumes and perfumed spirits, bay rum, cologne and lavender waters, hair, tooth and skin washes, and other toilet preparations containing spirits of any kind, when in bottles or flasks containing not more than 1 oz. each.	50 % ad val.
	Do., when in bottles, flasks, or other packages, containing more than 1 oz. each.	Per gall. 2 40 and 40 % ad val.

No.	Article.	Rate of Duty.
		Dols. Cts.
	Spirituos or alcoholic liquors—cont.	
	(d.) Nitrous ether, sweets spirits of nitre and aromatic spirits of ammonia.	Per gall. 2 40 and 30 % ad val.
	(f.) Medicinal or medicated wines containing not more than 10 per cent. of proof spirits.	Per gall. 1 50
	Animals, and Agricultural, Animal and Dairy Products.	
18	Lard, lard compound, and similar substances, cotton lme, and animal steaming of all kinds, n.e.s.	Per lb. 0 2
19	Tallow and stearic acid.	20 % ad val.
20	Beeswax.	10 % ad val.
21	Candles, n.e.s.	25 % ad val.
22	Paraffin wax candles.	30 % ad val.
23	Soap, common or laundry.	Per lb. 0 1
24	Castile soap, mottled or white.	Per lb. 0 2
25	Soap, n.e.s.	35 % ad val.
26	Pearline and other soap powders.	34 % ad val.
27	Gum, liquid, powdered or sheet, and emulsion, gelatine, and isinglass.	25 % ad val.
69	Extract of malt (non-alcoholic) for medicinal and baking purposes.	25 % ad val.
72	Yeast cakes and baking powder, the weight of the packages to be included in the weight for duty.	Per lb. 0 6
	Books and Paper.	
123	Albumenized and other papers and films chemically prepared for photographers' use.	30 % ad val.
	Chemicals and Drugs.	
141	Acid, acetic acid, and pyroigneous, n.e.s., and vinegar, for each gallon of any strength not exceeding the strength of proof.	Per gall. 0 15
	[And in addition, for each degree of strength in excess of the strength of proof, an additional duty of two cents.]	
	The strength of proof shall be held to be equal to 6 per cent. of absolute acid; and in all cases the strength shall be determined in such manner as is established by the Governor in Council.	
142	Acid, acetic acid, crude, and pyroigneous crude, of any strength not exceeding 30 per cent.	25 % ad val.
143	Acid, muriatic and nitric, and all mixed or other acids, n.e.s.	20 % ad val.
144	Acid, sulphuric.	25 % ad val.
145	Acid phosphate, n.o.p.	25 % ad val.
146	Sulphuric ether, chloroform, and solutions of peroxides of hydrogen.	25 % ad val.
147	All medicinal, chemical, and pharmaceutical preparations, when compounded of more than one substance, including patent and proprietary preparations, tinctures, pills, powders, troches, lozenges, syrups, cordials, bitters, anodynes, tonics, plasters, liniments, salves, ointments, pastes, drops, waters, essences, and oils, n.o.p.; provided that drugs, pill-mass, and preparations, not including pills or medicinal plasters, recognised by the British or the United States Pharmacopoeia or the French Codex as official, shall not be held to be covered by this item; all liquids containing alcohol.	50 % ad val.
	And all others, liquid or not.	25 % ad val.
149	Perfumery, including toilet preparations (non-alcoholic)—viz., hair oils, tooth and other powders and washes, pomatums, pastes, and all other perfumed preparations, n.o.p., used for the hair, mouth, or skin.	30 % ad val.
151	Paraffin wax.	20 % ad val.
152	Antiseptic surgical dressing, such as absorbent cotton, cotton wool, lint, lambswool, tow, jute, gauzes, and cakum, prepared for use as surgical dressings, plain or medicated.	20 % ad val.
154	Cod liver oil.	20 % ad val.
	Colours, Pigments, Oils, Varnishes &c.	
158	Dry white and red lead, orange mineral, and zinc white.	5 % ad val.
159	Ochres, ochry earths, raw siennas and c. d. d. dry, n.e.s.	20 % ad val.

No.	Article.	Rate of Duty.	No.	Article.	Rate of Duty.
160	Oxides, umbers, burnt siennas, and fireproofs, n.e.s.; laundry bluing of all kinds, rough stuff, and dye and liquid fillers, anti-corrosive and anti-fouling paints commonly used for ships' hulls, and ground and liquid paints, n.e.s.	25 <i>ad val.</i>	209	Bent plate or other sheet glass, and all other glass, and manufactures of glass, n.o.p.	20 <i>ad val.</i>
161	Paints and colours, ground in spirits, and all spirit varnishes and lacquers.	Dols. Cts. Per gall. 1 12	212	Leather, Rubber, and Manufactures of.	Dols. Cts. 0 17½
162	Paris green, dry	10 <i>ad val.</i>	213	Donkey, cordovan, calf, sheep, lamb, kid or goat, kangaroo, alligator, or other upper leather, and all leather, dressed, waxed, glazed, or further finished than tanned, n.e.s.; harness leather, and clamois skin.	15 <i>ad val.</i>
163	Ink for writing	20 <i>ad val.</i>	214	Skins for morocco leather, tanned, but not further manufactured; soft leather and belting leather of all kinds; tanners' scrap leather; and leather and skins, n.o.p.	10 <i>ad val.</i>
164	Blacking, shoe, and shoe-makers' ink; shoe, harness, and leather dressing, harness soap, and knife or other polish or composition, n.o.p.	25 <i>ad val.</i>	215	Glove leathers, tanned or dressed, coloured or uncoloured, when imported by glove manufacturers for use in their own factories in the manufacture of gloves.	25 <i>ad val.</i>
165	Putty, of all kinds	5 <i>ad val.</i>	216	Japaned, patent, or enamelled leather, and morocco leather.	25 <i>ad val.</i>
166	Turpentine, spirits of	19 <i>ad val.</i>	220	Leather-board, leather-rod, and manufactures thereof, n.o.p.	25 <i>ad val.</i>
167	British gum, dextrine, sizing cream and enamel sizing.	20 <i>ad val.</i>	221	Manufactures of raw hide, and all manufactures of leather, n.o.p.	25 <i>ad val.</i>
168	Varnishes, lacquers, japans, japan driers, liquid driers, and oil finish, n.e.s.	Per gall. { 0 20 and 20 <i>ad val.</i>	222	India rubber boots and shoes; and all manufactures of india rubber and gutta-percha, n.o.p.	35 <i>ad val.</i>
169	Linseed or flax seed oil, raw or boiled, lard oil, neat-foot oil, and sesame seed oil.	25 <i>ad val.</i>	223	India-rubber clothing, and clothing made waterproof with india-rubber, rubber or gutta-percha hose, and cotton or linen hose lined with rubber, rubber mats or matting, and rubber packing.	35 <i>ad val.</i>
170	Illuminating oils composed wholly or in part of the products of petroleum, coal, shale, or lignite, costing more than 30 cents per gallon.	25 <i>ad val.</i>		<i>Metals and Manufactures of.</i>	
171	Lubricating oils, composed wholly or in part of petroleum, costing less than 25 cents per gallon.	Per gall. 0 5	225	Ferro-silicon, ferro-manganese, and spiegeleisen.	5 <i>ad val.</i>
172	Crude petroleum, fuel and gas oils (other than naphtha, benzine, or gasoline), when imported by manufacturers (other than oil refiners), for use in their own factories for fuel purposes or for the manufacture of gas.	0 2½	226	Chrome steel	15 <i>ad val.</i>
173	Oils, coal and kerosene distilled, purified or refined, naphtha and petroleum, and products of petroleum, n.e.s.	0 5	227	Brass wire, plain	10 <i>ad val.</i>
174	Barrels, containing petroleum or its products, or any mixture of which petroleum forms a part, when such contents are chargeable with a specific duty.	Each 0 20	228	Copper wire, plain, tinned or plated	15 <i>ad val.</i>
175	Lubricating oils, n.e.s., and axle grease	25 <i>ad val.</i>	229	Wire cloth, or woven wire of brass, or copper.	25 <i>ad val.</i>
176	Olive oil, n.e.s.	20 <i>ad val.</i>	230	Wire of all metals and kinds, n.o.p.	20 <i>ad val.</i>
177	Essential oils	10 <i>ad val.</i>	231	Lead, old, scrap, pig, and block	15 <i>ad val.</i>
178	Vaseline, and all similar preparations of petroleum for toilet, medicinal, or other purposes.	35 <i>ad val.</i>	232	Lead, in bars, and in sheets	25 <i>ad val.</i>
	<i>Earthenware, Cements, Slate, and Stoneware.</i>		233	Lead pipe, lead shot, and lead bullets.	35 <i>ad val.</i>
187	Cement, Portland and hydraulic or water lime, in bags, barrels, or casks, the weight of the package to be included in the weight for duty.	100 lb. 0 12½	234	Lead, manufacture of, n.o.p.	30 <i>ad val.</i>
188	Plaster of Paris, or gypsum, ground, not calcined.	15 <i>ad val.</i>	235	Brass and copper nails, tacks, rivets and burrs or washers; bells and gongs, n.e.s., and all manufactures of brass or copper, n.o.p.	30 <i>ad val.</i>
189	Plaster of Paris, or gypsum, calcined or manufactured, the weight of the package to be included in the weight for duty.	100 lb. 0 12½	236	Zinc, manufactures of, n.o.p.	25 <i>ad val.</i>
	<i>Glass and Glassware.</i>		237	Nickel anodes	10 <i>ad val.</i>
201	Common and colourless window glass, and plain coloured, opaque, stained, or tinted or muffled glass, in sheets.	20 <i>ad val.</i>	238	Celluloid, moulded into sizes for handles of knives and forks, not bored nor otherwise manufactured; also, moulded celluloid balls and cylinders, coated with tin foil or not, but not finished or further manufactured, and celluloid lampshade blanks.	10 <i>ad val.</i>
202	Ornamental, figured, and enamelled coloured glass, vitrified or painted, chipped, figured, enamelled, and obscured white glass, stained glass, windows and memorial, or ornamental window glass, n.o.p., and rough rolled plate glass.	30 <i>ad val.</i>	239	Britannia metal, nickel silver, Nevada and German silver, manufactures of, not plated, and manufactures of aluminium, n.o.p.	25 <i>ad val.</i>
203	Plate glass, not bevelled, in sheets or panes, not exceeding twenty-five square feet each, n.o.p.	25 <i>ad val.</i>	240	Sterling or other silver ware, nickel-plated ware, gilt or electro-plated ware, wholly or in part, of all kinds, n.e.s.	30 <i>ad val.</i>
204	Plate glass, not bevelled, in sheets or panes, n.e.s.	35 <i>ad val.</i>	241	Telephone and telegraph instruments, electric and galvanic batteries, electric motors, dynamos, generators, sockets, insulators of all kinds; and electric apparatus, n.e.s.	25 <i>ad val.</i>
205	Plate glass, bevelled, in sheets or panes, n.o.p.	35 <i>ad val.</i>	242	Electric light carbons and carbon points, of all kinds, n.e.s.	35 <i>ad val.</i>
206	Silvered glass, bevelled or not and framed or not.	35 <i>ad val.</i>	243	Carbons over six inches in circumference.	15 <i>ad val.</i>
207	German looking-glass plate, thin plate, unsilvered or for silvering.	20 <i>ad val.</i>	244	Rabbit metal, type metal, phosphor tin, and phosphor bronze in blocks, bars, plates, sheets, and wire.	10 <i>ad val.</i>
208	Glass demijohns or carboys, empty or filled, bottles, decanters, phials, glass jars and glass balls, lamp chimneys, glass shades or globes, cut, pressed, or moulded crystal or glass tableware, decorated or not, and blown glass tableware.	30 <i>ad val.</i>			

(To be continued.)

## UNITED STATES.

## Customs Regulations.

Sulphite of soda and chloride of magnesium are liable to duty at 25 per cent. *ad valorem*, under paragraph 60 of the Tariff Act of August 28, 1894.

## AMERICAN DRAWBACK ON ALCOHOLIC PREPARATIONS.

*Chem. and Druggist*, Aug 9, 1897, 225.

The American Government have made it known that they will in future allow a drawback on certain exported spirituous preparations, such as essences of camphor and peppermint, equal to the amount of duty paid on the alcohol used in the preparations, less 1 per cent.

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

## NEW MARGARINE LAW IN GERMANY.

*Board of Trade J.*, Aug. 1897, 204.

A despatch, dated 8th July last, has been received at the Foreign Office from Sir Frank C. Lascelles, Her Majesty's Ambassador at Berlin, enclosing memorandum of the new German Margarine Law of 1897, which states that, with reference to those clauses which come into force on October 1st, 1897, the Bill that recently passed the Reichstag and became law, left to the Bundesrath the task of settling the form or method to be employed to render margarine distinguishable from butter when used for trade purposes.

On July 2nd the "Diet" concluded its labours on this subject, and decreed that in order to facilitate its recognition in trade, "sesamol" ("Sesamum orientale") is to be added to it in the preparation of all fats and oils. To 100 parts of the used fats or oils the addition of margarine must be 10 parts of "sesamol," and to margarine cheeses at least 5 parts. For the casks or coverings in which margarine, its cheeses, &c., are to be sold, models are supplied giving the dimensions and position of the lettering, red bands, &c. The name or firm of makers, as also the maker's mark, are to be placed close to the lettering without going over the red bands. The lettering and maker's mark are to be burned or painted on. If done in the latter way they are to be painted in black letters on a white or light yellow ground. The lettering and marks are to appear twice at opposite ends or sides of the barrels or coverings.

## RUBBER IN TONKIN.

A correspondent writes to the *Bulletin de la Société de Géographie Commerciale*, Paris, Vol. XLN., No. 5, that he has discovered, after investigation, that a tree which grows abundantly in Tonkin is the same as the *Ficus elastica*, which is cultivated in Brazil, Bolivia, the Guianas, &c. There is a good opening, he thinks, for a new industry in Tonkin, especially as labour is cheap and easily obtained.

## GENERAL TRADE NOTES.

## TUNISIAN TRADE IN CHEMICAL PRODUCTS AND IN ALCOHOLS.

*Board of Trade J.*, Aug. 1897, 221.

The Belgian Consul-General at Tunis has reported specially to his Government on the importation into Tunis of those products which concern chiefly pharmacists, druggists, and wine producers.

These products, the Consul-General states, are not subject to much fluctuation in the market, as are articles of fashion, or those which can be improved by new inventions. It is sufficient to create a connection and revise it occasionally to maintain confidence.

The value of the importation into Tunis of the above-named products amounted in 1896 to over 1,200,000 francs (48,000*l.*). Of this amount alcohol alone stands for 20,000*l.*; it is principally used by wine-growers for fortifying wines.

## MINERAL OUTPUT IN U.S.A.

*Chem. and Druggist*, Aug. 7, 1897, 225.

The annual report for 1896 of Dr. David T. Day, Chief of the Division of Mineral Resources in the United States, gives the following particulars concerning the output of minerals in that country:—"The bromine-industry is chiefly in the hands of a syndicate. In 1896 it showed a slight increase to 346,580 lbs., valued at the works at 144,501*l.*, compared with 317,421*l.*, worth 134,343*l.*, in 1895. The output for 1896 includes the bromine in potassium bichromide

made directly. The sulphur output rose from 1,800 tons in 1895 to 5,260 tons in 1896. The increase was due to the success attending the working of the Louisiana deposits by Frasch's process. The increased price, due to the Sicilian-sulphur combination, excited search for other deposits, with the result of attracting some attention to the deposits in Texas. The same fact is the cause that, in spite of low prices, search for a more extended supply of pyrites in the United States is quite active in consequence of the higher price of sulphur. The barax output went up to the normal level of 13,508,000 lbs., worth 675,400*l.*, all from California and Nevada. In infusorial earth there was a slight decrease in product to a value of 16,792*l.*, against 20,514*l.*, in 1895. The mineral-waters industry showed an increase in quantity from 21,463,543 galls. in 1895 to 21,668,345 galls. in 1896, but there was a decline in the total value from 4,254,237*l.* in 1895 to 4,005,688*l.* in 1896. There were produced 60,000 flasks (4 590,000 lbs.) of quicksilver in 1882, but 10 years later production had fallen to about one-third of this. Since then the product has gained slowly to 30,765 flasks in 1896. The industry, though still practically confined to California, is slowly extending into Oregon. No development has been made of the deposit recently found in Texas."

## THE PRODUCTION OF SODA.

*Ch. of Com. J.*, July 1897, 152.

*Handels-Museum* reports that the production of ammonia-soda in Germany again increased last year. Two new factories were built. The total production of soda in the world is now estimated at 1½ million tons. Abroad also this branch of industry is constantly on the increase. North America, hitherto the largest buyer of English Leblanc soda, has increased its production of ammonia soda from 60,000 to 80,000 tons. Russia consumes a total of about two millions of pounds of calcined soda. Of these the Russian factories produce about 1,800,000 pounds, whilst about 200,000 pounds are imported.

## PLATINUM IN RUSSIA.

*Ch. of Com. J.*, July 1897, 150.

The Russian Ministry of Finances has recently issued a report on the production of platinum in Russia, according to which that country stands first in the world for this production, 40 times the quantity produced by all other countries together being obtained there. In the year 1880 the quantity produced amounted to 2,946 kilograms; in 1895 it reached 4,413 kilograms. The production had gone on increasing up to the last year, when it diminished on account of the wet weather in summer. This rare metal is found exclusively in the Southern Ural. The manner of its being worked up is unknown in Russia; this is done in Germany, to which country the platinum is exported in a crude state. Whatever Russia requires of worked-up platinum, it has to buy back from Germany. Of late years the price of this article has run very high; at present it is 900 marks (about *str.* 45*l.*) for 1 kilogram of crude platinum in Russia. On mining for the platinum the still rarer metal iridium is also found, but only in very small quantities. Last year the total quantity of iridium obtained did not amount to more than 4·1 kilog., and this was only slightly exceeded in 1894.

## BOARD OF TRADE RETURNS.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

16,989. J. E. Slack and D. Rushworth. Improvements in the manufacture of tubes in apparatus for heating and cooling fluids. July 19.

17,099. O. H. Pieper and A. F. Pieper. Rheostats. Complete Specification. July 20.

17,356. W. G. Heys.—From J. Klein, of the Maschinen und Armaturfabrik vormals Klein, Schanzlin, and Becker, Germany. Improvements in apparatus for cooling liquids. Complete Specification. July 23.

17,475. Forbes, Abbott, and Lennard, Ltd., and L. Gaster. Improvements in and apparatus for use in subjecting air or other gases or liquids or solids to the action of air, gases, or liquids; applicable also for mixing, cooling, heating, and other analogous operations. July 24.

17,712. J. Lehmann and A. Scrigiers. Apparatus for compressing gas. July 28.

17,714. J. Buchanan, jun. Improvements in appliances for discharging coke and like ovens. July 28.

18,189. O. Guttman. See Class VII.

18,311. L. A. Chevalet and W. Boby. Improvements in apparatus for heating and purifying water. Aug. 6.

18,454. D. W. Forbes and W. Kemp. Conical vaporiser. Aug. 9.

18,460. M. J. Kelly. An improved composition for removing and preventing incrustation and corrosion in steam and water boilers and cisterns. Aug. 9.

18,578. H. Hirzel. An improved absorption apparatus for absorbing gases in liquids. Complete Specification. Aug. 10.

18,655. J. C. Montgomerie. Improvements in filter presses and in cloths therefor. Aug. 11.

18,816. L. Fremy. An improved apparatus for sterilising liquids and for use as a receptacle for containing the same. Date applied for March 18, 1897, being date of application in France. Complete Specification. Aug. 13.

18,819. W. R. Renshaw. Improvements in apparatus suitable for cooling liquids and condensing. Aug. 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

##### 1896.

22,777. T. Levoz. Converters. Aug. 18.

22,811. F. N. Cockson and J. Stewart. Means for providing for the collection and removal of saline and other deposits from steam boilers, evaporators, and the like. Aug. 18.

##### 1897.

5823. Maigen's "Filtre-Rapide and Anti-Calcaire" Co., Ltd., and A. A. Ellis. Treatment of water or other liquids with powdered material. Aug. 4.

16,035. A. J. Boulton.—From A. G. Waterhouse and A. W. Case, United States. Heating fluids and distilling. Complete Specification. Aug. 11.

16,237. P. Gerlach. Cooling apparatus for beer and other liquids. Complete Specification. Aug. 18.

16,398. R. Hadjan.—From H. Colberg, A. Serret, and F. Amigo. Improved furnace for the production of carbide of calcium. Complete Specification. Aug. 18.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

17,021. E. Godin. Improvements in acetylene gas generators. Complete Specification. July 19.

17,090. E. Barnard. An improved apparatus for the generation of acetylene gas or other gases. July 20.

17,327. W. B. Hartridge. An improvement in fuel blocks. July 22.

17,448. R. F. Carter. Improved apparatus for the production and storage of acetylene gas. Complete Specification. July 24.

17,482. N. Reggiani and A. Chrisini. Improvements in acetylene gas generators. Complete Specification. July 24.

17,635. H. C. B. Forester and The Patent Agglomment Fuel Syndicate, Ltd. Improvements in or relating to the manufacture of artificial fuel. July 27.

17,644. H. H. Lake.—From Fellner and Ziegler, Germany. Improvements in apparatus for purifying gas by washing or scrubbing. July 27.

17,749. V. B. Lewes. Improvements in and apparatus for the manufacture of illuminating gas. July 28.

17,793. J. G. A. Kitchen. Improvements in or connected with acetylene generators. July 29.

17,813. P. Dumont. Improvements in acetylene apparatus. July 29.

17,884. H. Muratet and J. Bessac. Improvements in acetylene gas generators. July 29.

17,883. R. Rousselet and A. de Latronsse. Improvements in acetylene gas generators. July 30.

17,927. M. Bernstein. Improvements in petroleum blue flame burners for incandescent lighting and heating purposes. Complete Specification. July 30.

17,938. A. Rieffel. Improvements in apparatus for the production of acetylene gas. Complete Specification. July 30.

17,976. E. Gobbe. Improvements in and apparatus for the manufacture of gas and the obtainment of bye-products therefrom. July 31.

18,005. W. P. Thompson.—From A. Julien, Belgium. Improvements in and relating to apparatus for producing heating or lighting gas by the aid of volatile hydrocarbons. Complete Specification. July 31.

18,056. P. Imbert-Rolland. Improvements in acetylene gas generators. Aug. 3.

- 18,085. W. Young and A. Bell. *See* Class III.
- 18,128. F. Goulding. Improvements in apparatus employed in the production of acetylene gas. Aug. 3.
- 18,218. F. H. Smith. Improvements in the preparation of calcium carbide and the like for use in gas generators. Aug. 5.
- 18,345. G. Webb, jun., J. W. Kelly, and H. Rountree. Improvements in apparatus for the production of carbide of calcium. Aug. 6.
- 18,355. J. C. Bull.—From Jossé and Defays, France. Improvements in and relating to the manufacture of acetylene gas. Aug. 6.
- 18,360. G. Daubenspeck. Improvements in and relating to refractory incandescent mantles or hoods. Aug. 6.
- 18,481. G. F. Dinsmore. Improvements relating to the transmission of heat for making water-gas, generating steam, melting refractory material, and the like, and to apparatus therefor. Date applied for Jan. 11, 1897, being date of application in United States. Aug. 9.
- 18,528. J. B. Lavanr. Improvements in acetylene gas generators. Aug. 10.
- 18,565. E. J. Clubbe, A. W. Southey, and The Electric Motive Power Company, Ltd. Improvements in the generation of oil-gas. Aug. 10.
- 18,603. T. Mitchell. Improved apparatus for the generation and storage of acetylene and other gases. Aug. 11.
- 18,639. F. J. Collin. Improvements in coke-ovens. Aug. 11.
- 18,744. Sir C. S. Forbes, Baronet. Improvements in or connected with acetylene lamps. Aug. 12.
- 18,745. Sir C. S. Forbes, Baronet. Improvements in generators for acetylene gas. Aug. 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 13,511. A. F. Bowers. Regulators and gas-holders for acetylene gas. July 28.
- 17,209. G. C. Fowler and M. B. Fowler. Manufacture of night lights. Aug. 4.
- 17,904. H. H. Lake.—From O. Grenier and J. Grand. Apparatus for generating and utilising acetylene gas for lighting purposes. July 28.
- 18,915. B. Kosmann. Separation of certain rare earths, and the manufacture therefrom of fabrics for use in incandescent gas-lighting. July 28.
- 20,074. G. W. Gaskell and R. R. Gibbs. Generation and storage of acetylene. Aug. 4.
- 20,125. W. Young, S. Glover, and T. Glover. Manufacture of illuminating gas. Aug. 18.
- 20,225. P. Fritzsche. Obtaining ether from gases containing ethylene and apparatus therefor. Aug. 11.
- 29,895. D. D. Esson. Combustible compound or fuel. July 28.
- 21,351. A. Kay. Apparatus for the generation and storage of acetylene gas. Aug. 4.
- 21,374. J. D. Palmer, H. Palmer, and H. E. Trestrail. Night lights. Aug. 11.
- 21,695. J. B. Fournier. Apparatus for containing and supplying liquefied gas for lighting and other purposes. Aug. 4.
- 21,698. A. H. Barker. Generators for acetylene gas. Aug. 4.
- 21,758. E. C. L. Pillion and C. Bertolus. Apparatus for generating and storing acetylene gas. July 28.
- 22,359. E. H. Maddock and W. Jones. Acetylene gas generators and gasometers. Aug. 18.
- 22,526. L. T. FitzGibbon. Production of acetylene gas. Aug. 18.
- 23,289. C. F. J. B. Beecherel. Apparatus for the manufacture of acetylene gas. Aug. 18.
- 23,290. C. F. J. B. Beecherel. Apparatus for the manufacture of acetylene gas. Aug. 18.

- 23,669. H. E. Oving. Process and apparatus for the production and treatment of acetylene. July 28.
- 23,670. H. E. Oving. Treatment of acetylene or other gases for lighting, heating, or other purposes. Aug. 4.
- 24,111. A. J. Smith and A. G. Smith. Automatic acetylene gas generator. Aug. 11.
- 24,119. P. de Resener and H. L. A. Luchaire. Apparatus for the manufacture of acetylene. Aug. 11.
- 29,551. H. K. Spence, A. Beveridge, W. G. Beveridge, and S. M. Beveridge. Acetylene gas generators.

1897.

9996. W. Baddens. Process for obtaining thorium oxide and for enriching monazite sands. Aug. 18.
- 13,103. F. H. Smith. Manufacture of calcium carbide and the like, and method of using the same in lamps or generators. Aug. 18.
- 14,471. H. A. Jones. Gas apparatus. Aug. 18.
- 14,814. S. Pitt.—From The Compagnie Internationale des Procédés A. Siegle, France. Apparatus for heating by means of liquid hydrocarbons. Aug. 4.
- 15,599. L. V. Pratis and P. Marengo. Apparatus for the manufacture or production of hydrogen gas. Aug. 4.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

##### APPLICATION.

- 18,085. W. Young and A. Bell. Improvements in the carbonisation or destructive distillation of coal, and in the production of carburetted water gas, and in apparatus therefor. Aug. 3.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

- 17,018. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of dyestuffs for cotton. July 19.
- 17,328. O. Imray.—From The Farbenwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of yellow azo dyestuffs fast to washing and light. July 22.
- 17,529. H. H. Lake.—From L. Dufour, Italy. *See* Class XIV.
- 17,729. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new anthraquinone dyestuffs. July 28.
- 18,002. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Manufacture of green and blue-green colouring matters from triphenylmethan. July 31.
- 18,017. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement Gilliard P. Monnet et Cartier, France. Improvements in and relating to the manufacture of dyestuffs. July 31.
- 18,376. I. Levinstein and Levenstein, Ltd. The manufacture or production of new colouring matters. Aug. 7.
- 18,494. J. Y. Johnson.—From C. F. Boehringer and Soehne, Germany. Improvements in the manufacture or preparation of amino- and hydrazino-derivatives of purine. Aug. 9.
- 18,762. A. Ashworth. Improvements in the manufacture of colouring matters suitable for dyeing unmordanted cotton. Complete Specification. Aug. 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 19,946. R. Blank. Manufacture of compounds of the series of the indoxyl acids and of dyestuffs of the indigo series. Aug. 4.

19,976. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Basic disazo colouring matters. July 28.

21,196. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Production of colouring matters. Aug. 4.

21,198. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Manufacture of colouring matters. Aug. 11.

22,041. O. Imray.—From The Farbwerke vormals F. Bayer and Co. Ortho- and para-nitrobenzyl aniline and its homologues. Aug. 11.

23,175. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. New violet mono-azo dye-stuffs for wool, dyeing a fast brown by oxidation with chrome. Aug. 4.

25,723. I. Levenstein and Levenstein, Ltd. Production of a new colour base and of colouring matters therefrom. Aug. 4.

1897.

12,963. L. Lederer. Production of indifferent (neutral) compounds of alkoxylated phenols. Aug. 18.

15,009. R. Barge. Separating ortho-anhydro-sulphamine-benzoic acid from para-sulphamine-benzoic acid. Aug. 4.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

### APPLICATIONS.

17,302. J. Wetter.—From Herberlien and Co., Switzerland. Improvements in the treatment of cotton yarn and other vegetable textile material for imparting to it a silk-like gloss. July 22.

17,397. H. A. Lowe. Improvements in the treatment of cotton or other vegetable fibres. July 23.

17,901. W. P. Dreaper and H. K. Tompkins. Improvements in the manufacture of artificial silk from suitable forms of cellulose. July 30.

17,959. G. Wendler and L. E. Wendler. Improvements in the method of and apparatus for treating textile fabrics having a vegetable origin. July 31.

18,222. W. Clegg. An improved method of treating animal fibres. Aug. 5.

18,471. T. H. Thate. Process for imparting to cotton and other vegetable fibres a silk-like appearance. Aug. 9.

18,472. S. Wolf. Manufacture of cloth felt and wadding from cellulose. Aug. 9.

18,473. S. Wolf. See Class XIX.

18,728. A. L. C. Nodon and L. A. Bretonneau. Improved process for decorticating and degumming Ramie and other like fibrous materials. Complete Specification. Aug. 12.

18,733. H. Ferguson. Improvements in the process and machinery for breaking and scutching fibrous plants and stems, such as brown rhea, ramie, hemp, jute, and the like. Aug. 12.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

19,217. A. Monforts. Machines for finishing yarns in the form of hanks or skeins. Aug. 4.

22,605. S. Whittaker. Machinery for preparing or spinning cotton or other fibrous materials. Aug. 4.

23,376. H. Giesler. Manufacture of mixed or parti-coloured fabrics. Aug. 4.

28,870. O. Seyfert. Process for giving a silk appearance to cotton. July 28.

1897.

11,804. A. H. Prinz. Treatment of jute, bast, china-grass, reed, and like plants for use in textile industries. Aug. 11.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

17,173. H. H. Lake.—From D. Mattei, Italy. Improvements in apparatus for dyeing textile fabrics. Complete Specification. July 20.

17,452. J. Smith. Improvements in or connected with dyeing textile materials aniline black, partly applicable also to dyeing textile materials other colours. July 24.

18,487. G. B. Ellis.—From J. Heilmann et Cie., Alsace. Improvements in the manufacture and in the production of coloured designs on woven fabrics. Aug. 9.

18,527. J. Grossmann. Improved method of dyeing cotton piece goods. August 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

19,428. J. Schneider. Improvements in the treatment of fibres and fibrous or textile materials to improve the appearance or finish and facilitate the operation of dyeing. July 28.

20,846. B. Lec. Vessels for dyeing purposes. July 28.

21,492. F. Davies and A. Liebmann. Machine for dyeing, finishing, sizing, washing, or similarly treating yarn. Aug. 4.

1897.

14,831. M. L. Kellogg. Improvements in dyeing hair or fur. Aug. 4.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

17,313. H. J. Krebs. Improvements in process of and apparatus for distilling ammonia. Complete Specification. July 22.

17,476. R. H. Davidson and The United Alkali Company, Ltd. Improvements in and apparatus for the manufacture of flowers of sulphur. July 24.

17,609. I. L. Roberts. Process of and apparatus for the manufacture of metallic carbides. Date applied for Dec. 29, 1896, being date of application in United States. Complete Specification. July 27.

17,683. F. H. Bowman and F. E. Bowman. Improved means and apparatus for electrolytically decomposing salts of the alkaline and earthy metals for the manufacture of caustic bleaching powder, chlorine, and other products contained in them. July 28.

17,834. E. F. Turner. Improvements in the treatment of metallic chlorides such as those produced from sulphide ores. Complete Specification. July 29.

17,930. C. J. Yarnold. Improvements in or relating to the manufacture of hydrogen peroxide. July 30.

17,931. J. C. Butterfield. Improvements in the oxidation of ferrous salts. July 30.

18,189. O. Guttmann. Improvements in apparatus for converting nitric peroxide into nitric acid. Complete Specification. Aug. 4.

18,271. E. L. Lalbin. An improved process for producing alkaline prussiates and cyanides and reproducing the reagents employed. Aug. 5.

18,417. O. Luppe. An improved process for the recovery of perchloride of iron from the solutions of perchloride of iron used for etching purposes. Aug. 7.

18,614. J. S. Rigby. New or improved applications of "waste" sulphuric acid, and apparatus for the utilisation thereof and the production of sulphates therefrom. Aug. 11.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

15,977. L. L. Billandot. Process of manufacturing phosphorus. July 28.

20,068. W. R. Clarke and The United Alkali Company, Ltd. Means for effecting the absorption of chlorine gas, applicable in the manufacture of chlorates and bleaching liquor. Aug. 11.

20,883. G. P. Lewis and R. A. Cripps. Improved means for manufacturing and recovering cyanides, and apparatus therefor. Aug. 4.

21,178. A. Schmitz and E. C. W. Toegeles. Obtaining tartaric acid and tartrates. Aug. 11.

21,953. T. Savage. Production of copper sulphate. July 28.

22,718. G. Kynoch and Co., Ltd., and A. T. Cocking. Process for denitrating acid which has been used in the nitro-glycerine manufacture. Aug. 18.

1897.

12,266. The Compagnie Generale L'Alumine. Manufacture of double chloride of aluminium and soda. July 28.

## VIII.—GLASS, POTTERY, AND ENAMELS.

### COMPLETE SPECIFICATIONS ACCEPTED.

1897.

11,630. C. C. Schirm and O. Lessing. Ceramic production of grinding agents. Aug. 18.

14,481. C. E. Blue, jun. Machines for the manufacture of glassware. Aug. 4.

15,618. T. Küpper. Apparatus for glass-blowing. Aug. 11.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

17,419. N. T. Ashton and J. Crompton. A new or improved manufacture of hydraulic cement. July 23.

18,046. J. Foster. Improvements in the construction of kilns for burning lime and other similar material. Aug. 3.

18,246. F. D. Cummer. Improved means applicable for use in the manufacture of cement. Aug. 5.

18,391. J. Parnall. Improvements in the manufacture of plaster or cement. Aug. 7.

18,672. E. Robbins. An improved compound concrete and means and methods of producing the same, and architectural and other works thereof, including shipbuilding and maritime works of concretion in general. Aug. 12.

18,779. T. Holden and C. Major. Improvements in apparatus for the manufacture of cement. Aug. 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

20,603. G. G. M. Hardingham.—From F. D. Cummer. Means applicable for use in drying cement, slurry, liquid, clay, and other substances in like condition. July 28.

20,612. P. Kleber. Manufacture of artificial stone. Aug. 18.

1897.

9316. L. S. Kasson. Treating and assembling the ingredients for the manufacture of paving compositions. Aug. 18.

12,024. J. C. Rombach and E. S. Restieaux. Improvements in cements for resisting the action of acids, acid vapours, and heat. July 28.

15,050. P. Rüchert. Artificial stones. Aug. 18.

## X.—METALLURGY, MINING, Etc.

### APPLICATIONS.

17,016. H. Birbeck.—From T. B. Birbeck, Western Australia. Improvements in or relating to extracting precious metals from their ores and apparatus therefor. July 19.

17,040. B. H. Springett.—From A. L. Lamsigne and A. H. V. Leblanc, France. Improvements in the process of gilding, silvering, nickeling, bronzing, plating, oxidising, and the like, on aluminium and its derivatives. July 19.

17,401. J. Armstrong. Improvements in the treatment of complex ores containing zinc. July 23.

17,566. L. Davies. Improvements in or connected with piles for making bar iron. July 27.

17,600. C. F. Claus. Improvements in the production of metallic zinc from blende. July 27.

17,624. H. E. Fry and R. H. Everitt. Improvements in the method of and apparatus for extracting lead with other metals from ores. July 27.

18,007. H. L. Sulman and H. F. K. Picard. Improvements in the recovery of gold from certain metallic products obtained in the extraction of precious ores. July 31.

18,135. T. Doherty. Method and means for manufacturing steel direct in a cupola. Aug. 3.

18,217. W. J. Wigge and E. G. Ballard. Improvements in the separation and recovery of zinc from liquors containing zinc in solution with iron and other metals. Aug. 5.

18,252. T. B. McGhie. Improvements in the recovery of precious metals from their solutions. Aug. 5.

18,339. F. B. Aspirall and E. C. Ekstromer. Improvements relating to the extraction of precious metals from their ores. Aug. 6.

18,607. W. Allen. A solder for uniting aluminium. Aug. 11.

18,640. J. Landin. Wet process for extracting gold from gold ores or gold ore waste. Complete Specification. Aug. 11.

18,712. A. Stein. Improvements in annealing or heating furnaces. Aug. 12.

18,731. F. George. An improved process of soldering aluminium. Complete Specification. Aug. 12.

18,787. J. B. Hannay and A. Cruikshank. Improvements in extracting gold and other metals from ores or minerals containing them, and apparatus therefor. Aug. 13.

18,802. J. Hall. Improvements in the manufacture of mild steel. Aug. 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

17,941. B. Thomas and J. W. Thomas. Elimination of arsenic from metallic copper. Aug. 11.

23,597. B. H. Thwaite and F. L. Gardner. Method of working iron blast furnaces as to utilise the gases evolved for producing motive power. Aug. 11.

1897.

8763. C. H. Foote, W. R. Walker, and E. A. S. Clarke. Manufacture of steel by the Bessemer or open-hearth process. Aug. 18.

11,996. G. Deer. Smelting of copper, and apparatus for that purpose. July 28.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

17,026. C. D. Abel.—From C. N. Sedneff, Russia. A new galvanic element. Complete Specification. July 19.

17,081. F. J. Patten. Improvements in and connected with electrical furnaces. July 20.

17,105. W. J. L. Sandy. Improvements in primary batteries. July 20.

17,158. W. Rowbotham. Improvements in electric batteries. July 20.

17,161. J. Hargreaves. Improved means applicable for use in the electrolysis of salts. July 20.

17,315. C. A. Meygret. An improved process for electrolytically purifying and filtering saccharine liquids or solutions. July 22.

17,316. L. G. Garcia. Improvements in accumulators. Complete Specification. July 22.

17,319. W. J. S. Barber-Starkey. Improvements in plates for secondary batteries. July 22.

17,471. C. D. Abel. From Siemens and Halske, Germany. Improvements in electric furnaces. July 24.

17,579. A. W. Southey. Improvements in secondary batteries. July 27.

17,837. J. Holloway. Improvements in apparatus for the electro-deposition of metals. July 29.

18,029. C. Marschner. An improved process for the manufacture of electrode plates for storage batteries. July 31.

18,176. A. Heil. Improvements in or relating to electrical accumulators or storage batteries. Aug. 4.

18,430. F. Pescetto. Improvements in the manufacture of electric accumulators. Complete Specification. Aug. 7.

18,564. E. J. Clubbe, A. W. Southey, and The Electric Motive Power Company, Ltd. Improvements in secondary batteries. Aug. 10.

18,566. E. J. Clubbe, A. W. Southey, and The Electric Motive Power Company, Ltd. Improvements in and connected with secondary batteries. Aug. 10.

18,616. R. Hurley, H. Cooney, J. Glover, and G. P. Campbell. Improvements in or connected with electrolytes for primary electric batteries. Aug. 11.

18,628. C. H. Cole. Improvements in portable electric primary batteries. Complete Specification. Aug. 11.

18,635. G. P. Torelli. Improvements in or relating to primary batteries. Aug. 11.

18,653. A. Nodon. Improvements in porous diaphragms and vessels for cells and accumulators. Aug. 11.

18,796. W. M. McDougall. Improvements in and connected with secondary or storage batteries. Aug. 13.

18,835. S. Ziani de Ferranti. Improvements in electrolytic cells. Aug. 14.

18,884. C. Zimmer. Improvements in and relating to the manufacture of plates for electric accumulators. Complete Specification. Aug. 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,597. R. M. J. Heartey and B. Cernain. Primary batteries. July 28.

18,046. M. M. Brophy and J. D. F. Andrews. Electric accumulators or secondary batteries. Aug. 18.

18,951. A. Conder and E. P. Michélot. Improvements in electrical accumulators. July 28.

21,027. W. L. Wise.—From The Aluminium Industrie Aktien Gesellschaft. Electrolytic apparatus. July 28.

21,509. J. G. A. Rhodin. Improved electrolyser or electrolytic apparatus. July 28.

21,749. The Sussmann Electric Miners' Lamp Co., Ltd., and S. A. Rosenthal. Active material for secondary battery plates. Aug. 11.

22,595. A. G. New. Electric accumulators. Aug. 18.

24,473. H. Leitner. Improvements in primary and secondary galvanic batteries. Aug. 4.

1897.

12,549. W. Majert. Plates for accumulators. Aug. 18.

12,827. V. Jeanty. Improvements in electric primary and secondary batteries. Aug. 11.

15,013. S. Pitt.—From L. Bomel and Société Bisson, Bergès, et Cie, France. Negative electrode for zinc accumulators. July 28.

15,510. J. Y. Johnson.—From J. P. Clare, G. E. Hatch, J. H. Taylor, United States. Improvements in secondary or storage batteries or accumulators and in the manufacture of the same. Aug. 4.

15,513. C. A. Jensen.—From P. Jebsen, Norway. Producing peat charcoal by means of an electrical current. Aug. 4.

16,069. L. W. Pullen. Electric batteries. Aug. 11.

16,361. E. W. Junger. Accumulator plates for secondary batteries. Aug. 18.

16,362. E. W. Junger. Electrodes of electric accumulators. Aug. 18.

#### XII.—FATS, OILS, AND SOAP.

##### APPLICATIONS.

17,405. A. J. Boulé.—From La Société "Meurice-Save-Simon," Belgium. Improvements in or relating to preparations for laundry purposes. July 23.

17,738. R. Gesell. Improved process for making soap. Complete Specification. July 28.

18,251. J. Hopkinson. Improvements in the treatment of wool grease, raw or distilled, and its derivatives. Aug. 5.

18,550. A. Euston. Improvements in apparatus for treating flax and other oleaginous seeds for the extraction of oil therefrom. Complete Specification. Aug. 10.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

17,118. F. V. Klever. Lubricants. July 28.

19,903. H. Hadfield. Manufacture of soap and in the frames used in the manufacture of soap and method of cutting or slabbing soap. Aug. 18.

21,048. E. S. Wilson and E. Stewart. Manufacture of soap. July 28.

1897.

15,156. A. Jolles. Manufacture of soaps. Aug. 4.

#### XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

##### APPLICATIONS.

17,674. E. Parkin. A new or improved process for treating vulcanised rubber to recover the india-rubber therefrom. July 28.

17,774. J. Noad. An improvement in the manufacture of white lead. July 29.

17,775. J. Noad. An improvement in the manufacture of white lead. July 29.

17,897. J. Livingstone and A. F. Crawford. An improved imperishable carbon paint. July 30.

17,936. W. Ramsay. Improvements in extracting and purifying gutta-percha. July 30.

18,331. W. Ramsay. Improvements in and relating to the treatment of gutta-percha and the like. Aug. 6.

18,519. I. Goldblum. Improvements in or connected with the manufacture of varnishes, paints, and the like. Aug. 10.

18,533. D. J. Ogilvy. Improvements in the method or process of making printing inks. Complete Specification. Aug. 10.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

19,310. J. Wetter.—From M. Weinrich. Revivifying bone black or animal charcoal. July 28.

19,788. A. C. J. Charlier. Manufacture of white lead. Aug. 18.

23,716. H. H. Lake.—From G. Hermegnies. Manufacture of zinc white. Aug. 18.

1897.

2108. G. L. Burnham. Paint for ships' bottoms. Aug. 18.

15,180. P. S. Watkins and P. J. Nunn. Manufacture of sealing wax. Aug. 4.

15,330. B. J. B. Mills.—From La Granitine Société Anonyme, Belgium. Manufacture of agglutinant enamels.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

17,529. H. H. Lake.—From L. Dufour, Italy. See Class XX.

18,332. E. J. Thibaut. Improved means to be used in tanning hides and skins. Aug. 6.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

22,103. J. Forster. Method of and means for tanning hides and the like. Aug. 18.

1897.

12,099. C. S. Dolley. Processes of tanning. July 28.

12,449. P. G. Sanford. Treatment of blood and other albuminous matter, both animal and vegetable, for use in manufactures and the arts. July 28.

#### XV.—AGRICULTURE AND MANURES, ETC.

##### APPLICATIONS.

17,926. W. E. Rowlands. Manufacture of manure from waste leather and phosphate of lime. Complete Specification. July 30.

18,491. J. Hudson. Improvements in the manufacture of manure from wool refuse. Aug. 9.

#### XVI.—SUGARS, STARCHES, GUMS, ETC.

##### APPLICATIONS.

17,444. J. Keil. Improved process and apparatus for the production of starch and gluten out of cerealia and legumines. Complete Specification. July 24.

18,429. L. Sternberg. Improvements in and connected with the extraction of sugar from molasses by the use of barium compounds. Complete Specification. Aug. 7.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

19,815. G. Ranson. Process for refining and purifying sugar. Aug. 18.

1897.

4467. E. R. Savigny. Sweetening substance and a process for its manufacture. Aug. 4.

15,295. L. P. Bauer. Manufacture of glucose or sugar. Aug. 4.

#### XVII.—BREWING, WINES, SPIRITS, ETC.

##### APPLICATIONS.

17,816. W. J. Glennon and A. Y. Oastler. An improved apparatus for aerating and sterilising beer. July 29.

18,112. H. H. Lake.—From L. S. Langville and H. Tauszky, United States. Improvements in and relating to the manufacture of yeast. Complete Specification. Aug. 3.

18,256. J. E. Carroll. Process and apparatus for maturing or treating wine and spirits. Aug. 5.

18,645. F. S. Masters and J. C. Shears. Improvements in the manufacture of beer and other liquids and in apparatus therefor. Aug. 11.

18,713. D. J. Etty and C. R. Long. An improved process of and apparatus for ageing whisky. Complete Specification. Aug. 12.

18,793. R. D. Bailey and L. P. Ford. An improved combined mashing vessel, raw grain conversion vessel, brewing copper, cooling apparatus, and hop back for boilers' and distillers' use. Aug. 13.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,011. G. E. Jacquemin. Improved method of and apparatus for the manufacture of pure yeasts. Aug. 18.

1897.

973. H. Muller-Thurgau. Process for production of non-alcoholic or feebly alcoholic fruit juices (fruit and grape wines) which may be kept or preserved without change. Aug. 18.

12,958. H. Krawsz and L. Vass. Process for utilising the waste of hops and malt of breweries. Aug. 4.

#### XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.

##### APPLICATIONS.

##### A.—Foods.

17,361. H. H. Christiansen. Improved process of treating margarine. July 23.

17,512. A. Searl. See Class XX.

17,915. S. Pitt.—From The Chemische Fabrik auf Actien vormals E. Schering, Germany. The production of food preparations containing casein. July 30.

18,072. J. Simmons. Food product. Aug. 3.

18,714. E. C. L. Kressel and T. Hill-Jones. The manufacture of an improved alimentary extract. Aug. 12.

##### B.—Sanitation.

17,261. J. B. Petrie. An improved method of purifying sewage and other foul waters by means of a secondary process following other primary processes. July 22.

18,555. W. D. Seett-Monerieff. Improvements in or relating to the purification of sewage, and apparatus therefor. Aug. 10.

18,839. B. C. Farmer. Improvements in the construction of precipitation tanks used in the filtration and treatment of sewage and other foul waters. Aug. 12.

##### C.—Disinfectants.

17,464. W. Loebinger. Improvements in or relating to disinfection by means of formaldehyde. Complete Specification. July 24.

18,178. W. L. Wise.—From Knoll and Co., Germany. Improvements in the manufacture of antiseptic substances. Aug. 4.

18,250. H. Oppermann. Process for the preparation of easily soluble compounds of formic aldehyde for preserving, disinfecting, and therapeutic purposes. Complete Specification. Aug. 5.

18,656. E. T. C. Weiher. Improved mixture for the destruction of microbes of the contagious diseases of animals, also applicable for the treatment of animal skins. Aug. 11.

##### COMPLETE SPECIFICATIONS ACCEPTED.

##### A.—Foods.

1896.

23,126. W. P. Thompson.—From Kietz and Co. Manufacture of strengthening and flavouring food extracts. Aug. 18.

1897.

7649. K. Franz. Improved food preparation and process for the manufacture thereof. Aug. 18.

##### B.—Sanitation.

1896.

23,042. D. Cameron, F. J. Commin, and A. J. Martin. Treatment of sewage or other liquids. Aug. 4.

## XIX.—PAPER, PASTERBOARD, ETC.

## APPLICATIONS.

17,736. T. Schiffer. Process for producing waterproof and washable glazed chromo-paper. Complete Specification. July 28.

18,473. S. Wolf. Improved manufacture of blotting paper, filter paper, and soft fibre-felt. Aug. 9.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

17,013. P. Sylva. A new or improved process for manufacturing chloride of ethyl. July 19.

17,169. A. F. Llobet. Improvements in the manufacture of milky juice of cereals. Complete Specification. July 20.

17,246. J. E. Lyndall and L. R. Orr. A liquid essence, and process for its manufacture. July 21.

17,409. O. Imray.—From the Society of Chemical Industry in Basle, Switzerland. Manufacture of new therapeutical compounds. Complete Specification. July 23.

17,512. A. Searl. Improvements in processes for the preparation of soluble and highly concentrated extracts of tea and coffee. July 26.

17,529. H. H. Lake.—From L. Dufour, Italy. An improved process for the preparation of extracts used in tanning and as colouring agents. July 26.

17,692. L. Lederer. Improvements in the process for preparing the halogen derivatives of acetone. Complete Specification. July 28.

17,693. L. Lederer. Improvements in the process for the preparation of hexymethylen-tetramin and its derivatives. Complete Specification. July 23.

18,478. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of pharmaceutical compounds. Aug. 9.

18,698. T. Bird. A process for the treatment of artificial camphor either in the crude state or after resublimation. Aug. 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

16,860. H. Higgins. Separation of caseinogen or casein from separated milk, and its preservation in a dry state. July 28.

18,981. A. Koelliker. Acid salts of piperazine and fatty acids, and the production therefrom of double salts of lithia and piperazine. July 28.

19,744. J. J. A. Trillat. Production of formic aldehyde vapours. Aug. 18.

20,622. G. B. Ellis.—From La Société Chimique des Usines du Rhône, anciennement G. P. Monnet et Cartier. Distributing formic aldehyde vapours. Aug. 4.

20,697. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering. Production of a vinylbi-acetonalkamine, and of anaesthetics therefrom. July 28.

20,773. J. J. A. Trillat. Production of vapours of formic aldehyde, and apparatus for the same. Aug. 4.

21,106. G. B. Ellis.—From La Société Chimique des Usines du Rhône, anciennement G. P. Monnet et Cartier. Manufacture of vanillin. Aug. 4.

29,447. O. Imray.—From F. Hoffmann, La Roche, and Co. Pure acetosulphanilate salts. Aug. 18.

1897.

14,610. B. Willecox.—From C. F. Boehringer and Soehne, Germany. Manufacture or preparation of theobromine. July 28.

14,611. B. Willecox.—From C. F. Boehringer and Soehne, Germany. Manufacture of iso-eugenol and derivatives thereof. July 28.

14,612. B. Willecox.—From C. F. Boehringer and Soehne, Germany. Production of trichloropurine. July 28.

## XXI.—PHOTOGRAPHY.

## APPLICATION.

17,122. G. J. Sershall and J. H. Kirk. An improvement or improvements in the production of coloured photographs. July 20.

## COMPLETE SPECIFICATION ACCEPTED.

1897.

11,133. G. Selle. Photographic dark backs for successive exposures for the purpose of colour photography. Aug. 4.

## XXII.—EXPLOSIVES, MATCHES, ETC.

## APPLICATIONS.

17,416. W. Hope. Improvements in pellets and grains of gunpowder of any kind. July 23.

17,417. W. Hope. Improvements in gunpowders and other explosives. July 23.

18,563. J. Caveri. Improvements in the manufacture of matches. Complete Specification. Aug. 10.

18,642. F. M. Hale, J. Deas, and J. B. Reavil. Improvements in percussion fuzes for explosive projectiles or shells. Aug. 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

17,307. C. E. Bichel. Manufacture of nitro-glycerine explosives. Aug. 11.

18,034. M. Bielefeldt. Manufacture of explosives. Aug. 18.

22,162. J. C. Hamiltou. Explosive compounds for blasting purposes. Aug. 11.

22,190. G. Kynoch and Co., Ltd., and A. T. Cocking. Manufacture of explosives. July 28.

22,718. G. Kynoch and Co., Ltd., and A. T. Cocking. See Class VII.

1897.

14,196. F. Volpert. Manufacture of explosives. Aug. 4.

14,989. J. T. Maguire.—From The Diamond Match Company, United States. Improvements in matches. July 28.

15,499. H. Maxim. Manufacture of explosive compounds. Aug. 4.

## PATENTS UNCLASSIFIABLE.

## APPLICATION.

17,610. J. Carnrick. A process of preparing proto-nuclein. Complete Specification. July 27.

## COMPLETE SPECIFICATION ACCEPTED.

1896.

17,717. F. J. Jones and G. W. Jones. A chemical compound. Aug. 11.

# THE JOURNAL OF THE Society of Chemical Industry.

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 9.—VOL. XVI.]

SEPTEMBER 30, 1897.

[Non-Members 30 per annum; Members 21 per Set of extra or back numbers; Single Copies (Members only) 2 6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Dr. Edward Schunck, F.R.S.	1896—1897.

## COUNCIL FOR YEAR ENDING JULY, 1898.

President: Prof. F. Clowes, D.Sc.

### Vice-Presidents:

David Howard.	Dr. W. Jay Schieffelin.
Prof. A. K. Huntington.	Dr. Edward Schunck, F.R.S.
Ivan Levinstein.	G. N. Stoker.
Boverton Redwood.	Dr. T. E. Thorpe, F.R.S.
Sir H. E. Roscoe, F.R.S.	Wm. Thorp, B.Sc.
A. Gordon Salamon.	Thomas Tyrer.

### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
R. Le Neve Foster.	J. S. McArthur.
Sir David Gamble, Bart., C.B.	B. E. R. Newlands.
Oscar Guttman.	John Pattinson.
Douglas Herman.	Sir Robert Pullar.
Prof. J. J. Hummel.	Walter F. Reid.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

### General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

#### The President.

A. H. Allen.	C. Clarke Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	J. Lewkowitzsch, Ph.D.
H. Brunner.	A. R. Ling.
A. C. Claudet.	Stevenson Macadam, Ph.D.
E. Rider Cook.	Ludwig Mond, F.R.S.
Chas. Dreyfus.	B. E. R. Newlands.
Sir John Evans, K.C.B., F.R.S.	John Pattinson.
G. G. Henderson, D.Sc.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	H. R. Procter.
D. B. Hewitt, M.D.	Boverton Redwood.
David Howard.	Walter F. Reid.
Prof. J. J. Hummel.	John Spiller.
Prof. A. K. Huntington.	William Thorp.
F. Hurter, Ph.D.	Thomas Tyrer.

## NOTICES.

### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, part of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List.

Each copy 10s.

To Subscribers ..... „ 12s. 6d.  
To others ..... „ 15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE,

the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

#### CHANGES OF ADDRESS.

- Ablett, A. W., 10 Johannesburg; 1, X.L. Cyanide Works, Sheba G. M. Co., Eureka City, Barberton, S.A.R.  
 Rambert, H. K. G.; Journals to Hill-side, Greenhithe, Kent.  
 Bischof, G., 10 Bloomsbury; 2, Hythe Road, Willesden Junction, N.W.  
 Bowman, R., 10 Elabouga; Victoria Chemical Works, Widnes.  
 Briggs, J. F., 10 India; 70, St. Ann's Hill, Wandsworth, S.W.  
 Church, E. D., jun., 10 Trenton; 65, Wall Street, New York, U.S.A.  
 Cooke, A. W., 10 Johannesburg; c/o Brotherton and Co., Holms Street, Dewsbury Road, Leeds.  
 Crow, H. W.; Journals to 11, Norwich Road, Forest Gate, E.  
 Douglas, Wm., 10 Stamford Hill; Diamond Plantation, Dennerara.  
 Elworthy, H. S., 10 India; c/o Henry S. King and Co., Cornhill, E.C.  
 Farrington, T., 10 Waterloo Place; 5, Summerhill Terrace, Cork, Ireland.  
 Garton, R. S., 10 Smethwick; retain Journals until further notice.  
 Griffith, D., Agnew, 10 Isle of Man; c/o Mitchell and Co., 27, King Street, Liverpool.  
 Horsman, F., 10 Forest Gate; 45, Hyde Vale, Greenwich, S.E.  
 Jarvis, Talbot, 10 Burton; Castle Lodge, Bedford.  
 Langer, Dr. C., 10 Hampton House; Upmore, Milverton, Leamington.  
 McEwen, Atholl F., 10 Laurie; retain Journals until further notice.  
 McFarland, B. W., 10 Temple Street; 355, Willow Street, New Haven, Conn., U.S.A.  
 McMillan, W. G., 10 Birmingham; 8, Leigham Court Road West, Streatham, S.W.  
 Queeny, John, F., 10 New York; c/o Meyer Bros. Drug Co., St. Louis, Mo., U.S.A.  
 Raymond, C. W., 10 Forest Gate; 32, Campbell Road, Bromley-by-Bow, E.  
 Russell, Dr. W. J.; Journals to 34, Upper Hamilton Terrace, N.W.  
 Sedding, G. H. P., 10 Auita; River Junction, Gadsden Co., Florida, U.S.A.  
 Shepherd, H. H. B., 10 Victoria Dock; Northcote, Mount Pleasant Lane, Upper Clapton, N.E.  
 Smith, H. Wood, 10 Battersea; 22, Great Winchester Street, E.C.  
 Thornton, H., 10 London; Redbourn House, Ford Road, Ashford, Middlesex.  
 Twitchell, E., 10 Mount Auburn; 9, Cumberland Building, Avondale, Cincinnati, Ohio, U.S.A.  
 Welch, J. Cuthbert, 10 Kaslo; Trail, British Columbia.  
 Wilson, Jno., 10 Stratford; 74, Bearwood Road, Smethwick, near Birmingham.  
 Zinkeisen, Dr. W., 10 George Street; 66, Virginia Street, Glasgow; Journals as before.

#### GOVERNMENT LABORATORY.

After October 4th, 1897, the address of the Government Laboratory will be Clement's Inn Passage, Strand, W.C., instead of Somerset House. The change affects the following members:—

- |                    |                   |               |
|--------------------|-------------------|---------------|
| *Thorpe, Dr. T. E. |                   |               |
| Baunister, R.      | *Holmes, J.       | *Proctor, C.  |
| Davis, H. W.       | Hooper, E. Grant. | Stoker, G. N. |
| *Helm, H. J.       | Lucas, A.         | *Woodward, J. |

The Journals of those marked with an asterisk are to be addressed as heretofore.

#### Deaths.

- Alsborg, Dr. M., Messrs. Soudheim Alsborg and Co., New York, U.S.A.  
 Fletcher, G., Poplar Ironworks, King Street, Poplar, E.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Zinc Plates as Covering for Steam Pipes.* Russner. Mitt. aus d. Praxis des Dampfkr. u. Dampfkr.-Betr. 1896, 334; Proc. Inst. Civil Eng. 1897, 128, [2], 49.

The author found that, compared with the naked pipe, a covering of one zinc plate (leaving a layer of air between plate covering and pipe) caused a saving of 83 per cent. of condensed water; a covering consisting of two plates, 86.6 per cent.; whilst a felt covering 0.6 in. thick, caused a saving of 91.4 per cent. The ordinary non-conducting coverings in use, effect the following savings in condensed water:—Kieselguhr, 0.8—0.9 in. thick, 70 to 75 per cent.; cork fibre, 2 ins. thick, 85 per cent.; soap waste, 1 in. thick, 85.6 per cent. Non-conducting compositions applied in a plastic state must be dried by the heat supplied of the steam pipe, and the cost of this drying is generally overlooked; further, owing to their greater thermal capacities, the cooling-down losses at the end of each day are much greater for the plastic coverings than for zinc plate coverings, while the latter compare favourably with the former in regard to first cost.—A. S.

*Steam, Superheated.* W. Ripper. Proc. Inst. Civil Eng. 1897, 128, [2], 5—46.

The author concludes, from the results of a number of trials, that a great improvement in steam-engine economy may be effected by the use of superheated steam. The temperature should be raised sufficiently high to secure dry steam in the cylinder throughout and up to release; for this purpose, the steam should be supplied at a temperature of about 650° F. at the engine. With steam at this temperature used in a simple non-condensing engine, the same power was obtained for less than half the steam required when no superheater was used. The increased economy in steam consumption which follows the increase of temperature of the steam, is also accompanied by a proportional reduction in the extent of the heat exchange between the steam and the cylinder walls; in fact, with the highest superheats and the highest economies, the cylinder walls approach the condition of being almost perfectly non-conducting. It is stated that the superheater tubes, after

\* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to C. N. Dalton, Esq., Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

long periods of severe work, show no signs of burning, scaling, or injury of any kind, and that with proper attention as to the judicious application of lubricating oils of good quality at the working parts, no trouble is likely to arise in the lubrication of superheated steam engines. Care should be taken, by the use of suitable non-conductors, to maintain the high temperature of the steam in its passage to the engine cylinders. The steam should be superheated at least 200° F. above its normal temperature, and in some cases still higher, depending on the number of expansions, else it will part with the whole of the added heat to the cylinder walls. The steam-admission valve of an engine to work with highly superheated steam, should be practically frictionless, so as to remove the necessity for concern as to lubrication.—A. S.

#### PATENTS.

*Dipping Ladles, An Impt. in.* O. Murray, 28, Southampton Buildings, Chancery Lane, London. From The Pennsylvania Salt Manufacturing Company, Philadelphia, U.S.A. Eng. Pat. 15,502, June 29, 1897.

THE apparatus comprises an overhead track, a trolley movable thereon, a hanger depending from the trolley and having an adjustable clutch consisting of two bars or parts (the one part at the side of and longitudinally adjustable along the other part), means for locking the sliding bar in any adjusted position, and a dipping ladle supported by a roller bearing within a ring connected by a swivel to the clutch.—R. A.

*Conveying and Distributing Heat to the Contents of Vessels, such as Stills and the like, or to the Interior of Steam-generating Vessels, Evaporating Pans, Boiling Pans, and the like, Improved Means for and Method of.* E. Martin and A. Stapley, both of Sugar House Lane, Stratford, London, E. Eng. Pat. 16,774, July 29, 1896.

THE heat is conveyed to the interior central parts of the distilling or other utensils by the employment of cones, cylinders, or other hollow heat conductors, adapted to any suitable part of the utensils.—R. A.

*Filtering Fluids [Water], Impts. in the Method of.* J. E. Bennett, Ridgway Street, Moss Side, Manchester, and H. Beresford, Tetlow Fold Farm, Gollery, Chester. Eng. Pat. 18,105, Aug. 15, 1896.

THE fluid to be filtered is caused to pass upward instead of downward, through the filtering medium, the solid matter collected being allowed to gravitate gradually to the bottom of the vessel. The filtering medium is cleaned by cutting off the supply and causing the body of filtered liquid above the medium to pass downward through the same.—R. A.

*Filter Presses [Sludge], Impts. in.* S. H. Johnson, Stratford, London, E. Eng. Pat. 9582, April 15, 1897.

RELATES to improvements in the class of filter presses such as that described in the specifications of Eng. Pats. 7045 and 14,415, both of 1886, in which fluid pressure is employed for pushing the plates or frames, which form the filter cells, into juxtaposition to effect the closing of the joints. In the present invention, the filter press is worked in combination with a differential intensifier reacting on a hydraulic ram, in which the working pressure of the feed liquor before entering the filter chambers, exerts pressure externally on the movable head or follower, in excess of the internal pressure, the condition being that the internal pressure within the cells, tending to force open the joints, shall be exceeded by the external pressure tending to force them together, so as to maintain the cell-joints fluid-tight, no matter what the working pressure may be. The external and internal pressures are both derived from the feed pressure, and are interdependent. When the sludge is very gritty, or likely to injure the interior surface or the cup-leathers of the intensifier, the external pressure is obtained from an auxiliary water-forcing receiver actuated by air pressure common to both the sludge

and water forcing receivers, the intensifier in this arrangement being operated by clean water instead of by the feed liquor.—R. A.

*Filtering Liquids, Impts. in the Process of and Apparatus for.* E. Simoneton, 15, Rue des Haïles, Paris. Eng. Pat. 11,700, May 11, 1897.

FILTERING apparatus is employed into which the liquid is introduced directly, or through a transparent inspection chamber, or in which the liquid may be subjected to preliminary filtration, the filtering body within the apparatus being formed by superposed discs or rings of a flexible filtering medium, such as non-metallic fabric or paper. The rings filter edgewise and radially into a central running-off chamber or passage, and can be more or less compressed together during filtration.—R. A.

*Carboys, Demijohns, and the like, Impts. in.* W. R. Lake, 45, Southampton Buildings, Middlesex. From R. Spaciani, Milan, Italy. Eng. Pat. 19,297, Sept. 1, 1896.

GLASS receptacles, such as carboys, demijohns, &c., are provided with protecting envelopes or coverings consisting of fibrous or cellular vegetable substances (cork shavings, sawdust, bark, chopped straw, or other waste), which are caused to adhere to the outer surface of the glass by uniting them with mastic, or by surrounding them with jackets of cloth, thin metallic plates, wire gauze, or the like.—R. A.

*Concentration of Liquids [Wine, Cider, Beer, Solutions, &c.], An Improved Process and Apparatus for the.* H. Baudoin and E. Schribaux, both of 11, Rue Michelet, Paris. Eng. Pat. 21,694, Sept. 30, 1896.

"THE apparatus" consists "of the combination, with ordinary heaters, analysers, and condensers, of an evaporator formed of sets of superposed series of tubes, discharging the vapours at both ends and then causing them to meet and combine in a common collector, the concentrated liquors being discharged below" and conveyed to a suitable receiver. The concentrated liquors and condensed vapours can be recombined, when desired, in another receiver, which is provided with a mechanical stirring or shaking device.

—R. A.

*Granulation of Crystallisable Liquids, An Improved Evaporating or Vacuum Apparatus for.* J. Grosse, Kiev, Russia. Eng. Pat. 27,477, Dec. 3, 1896.

THIS apparatus, which is fixed in an upright position, has an internal delivery pipe, within which a helical screw, worm vanes, or propeller blades rotate on a vertical shaft. The solution to be crystallised is by these means conveyed from the lower and hotter parts into the upper and cooler parts of the liquid. An evaporative and cooling action is produced, which is stated to considerably accelerate crystallisation.—J. L. B.

*Steam Boilers, An Improved Composition for Preventing Incrustation in.* L. Lewis, Pontyvain, Newport. Eng. Pat. 14,226, June 11, 1897.

APPLES, acorns, oak apples, and the "moss" or residue left after expressing the juice from cider-apples, are ground to a pulp and strained; the juice is then mixed with a lye made from oak bark and peat ashes.—L. A.

## II.—FUEL, GAS, AND LIGHT.

*Monazite in Idaho.* W. Lindgren. Eng. and Mining J. 1897. 64, 69.

See under XX., page 755.

*Air, Contamination of the, in the Purifying and Revivifying Houses of Gasworks.* H. Drehschmidt. J. für Gasbeleucht. 1897. 49, 517.

See under XVIII. B., page 752.

## PATENTS.

*Gas for Lighting and Motive Power, Impts. in the Production of, by the Cold Process, and Apparatus therefor.* C. Kremer, Gilly, Belgium. Eng. Pat. 19,953, Sept. 9, 1896.

THE generator is divided into several compartments by horizontal partitions, and the lowest charged with the petroleum or other carburetted liquid to be gasified. Air is then pumped in under pressure and the liquid thereby forced up a number of pipes leading to the next compartment, each pipe debouching into an atomiser shaped like a double truncated cone, whereby part of the liquid is very finely sprayed, the remainder falling back on to the floor of the compartment. This goes on at each stage until the topmost chamber is reached, and here the sprayed liquid and air impinge on a metal sheet, which retains most of the liquid particles, whilst the gas, passing through lateral screens of gauze, ascends through a large double cone fitted with similar screens (whereby the intimacy of the mixture is increased), and passes thence to the gas-holder, which may be superimposed or otherwise arranged. A suitable pipe is provided for the return of the liquid left unvaporised in the top compartment, to the bottom of the apparatus, and the movement of the gas-holder can be employed as a means of regulating the feed supply of oil, a constant level being maintained by a float valve in the lowest compartment.

—C. S.

*Carburetted Water-Gas, Impts. in the Manufacture of, and in Apparatus therefor.* W. R. Addicks, Boston, U.S.A. Eng. Pat. 1398, Jan. 19, 1897.

THE improvements consist in utilising the heat of the blast gas by finally passing it through the boiler generating the steam for the water-gas, and through the feed-water heater for the said boiler. Also in allowing the temperature of the carburetted gas to recede in the mixing chamber and then gradually raising it again by passage through an intermediate heated chamber on its way to the fixer, where the maximum is attained. Then, in order to prevent the injurious condensation resulting from the usual sudden cooling of the carburetted gases, they are first conducted through the aforesaid boiler and feed-water heater and thence to the condenser, the water in which is utilised for feeding the boiler, and so reducing the amount of water required for the process. The gradual cooling of the gas also obviates the inconvenience arising from heated tarry matters in the hydraulic main and tar well.—C. S.

*Carburetted Water-Gas, Improved Method and Apparatus for Making.* A. C. Humphreys and A. G. Glasgow, London. Eng. Pat. 11,130, May 1, 1897.

IN order to more fully utilise the heat generated in blowing up the generator, the inventors provide an additional regenerative chamber on each side of the (duplicate) apparatus, which is heated by the blast gases and serves in turn to heat the air and steam on their passage to the generator fire, so that the said air and steam may be also passed through the fixing and carburetted chambers without unduly lowering their temperature. The extra chambers are not traversed by the water-gas, this latter being drawn off from the fixing chambers into a receptacle common to both sides of the apparatus. On the completion of a gas-making run with one side of the apparatus, the reversal of the steam is secured by the same movement of the lever that shuts off communication between that side of the apparatus, with the gas receiver, and simultaneously opens the gas conduit leading to the latter from the other side.

—C. S.

*Carburetted Water-Gas, Improved Process and Apparatus for Making.* A. C. Humphreys and A. G. Glasgow, London. Eng. Pat. 11,131, May 1, 1897.

IN this invention the patentees, instead of duplicating the entire apparatus (as in the preceding abstract), provide two extra regenerative chambers to each set of generator, carburettor, and fixer, the said chambers being heated and utilised alternately.—C. S.

*Hydrogen Gas, Impts. in and connected with, and Apparatus for the Manufacture or Production of.* L. V. Pratis and P. Marengo, Turin, Italy. Eng. Pat. 15,509, June 29, 1897.

TO overcome the difficulties in the way of generating hydrogen from sulphuric acid and iron, the inventors propose to employ the following approximate proportions, by weight:—Broken iron, 5 parts; water, 5 parts; 50° B. sulphuric acid, 5·8 parts; these being found to produce a pasty non-caking residue, easy to remove from the apparatus and to work up for the manufacture of ferrous sulphate or Nordhausen sulphuric acid.

THE apparatus consists of a generating cylinder, fitted with a valve for discharging the residue. The acid and water are run in on to the charge of iron from reservoirs at a higher level, the supply valve being controlled by the bell of the gas-holder, and self-closing when the bell sinks below a certain level; or, if the gas is to be collected in receivers at high pressure, the full charge of liquids may be added at once. Purifiers are arranged between the generator and gas-holder, and an excessive rate of generation is prevented by gas checks, which cause an increase of pressure in the generator, whereby the acid is driven back in the supply pipe and the evolution of gas diminished.—C. S.

*Smoke consuming Hydrocarbon Furnaces, Impts. in or connected with.* L. E. Fraipont, Paris. Eng. Pat. 19,860, Sept. 8, 1896.

FURNACES for burning gaseous fuel are formed of two horizontal fire-brick or tile floors, one above the other, the lower perforated with small holes to allow a regulated amount of air to enter, the upper perforated with larger holes having flanged caps of suitable refractory material, while between the two, pass several parallel gas-supply pipes, each having a number of nozzles, one under each capped opening. In use, both floors become heated. The air is heated while passing through the lower floor, and the gas also is heated before reaching the nozzles. The gas and air are thoroughly mixed by the caps, and form a compound which then ignites.—R. S.

*Furnaces, Impts. in Apparatus for Burning Liquid Fuel in.* C. MacC. Sharp, Greenock, N.B. Eng. Pat. 21,341, Sept. 26, 1896.

A VAPORISER is fixed within the furnace, being connected at its upper end to a supply of water or steam under pressure, whilst the steam generated or superheated therein is led off by a pipe passing nearly from the top and through the bottom to a jet nozzle or nozzles having a chamber connected to an oil supply tank. The vaporiser is first heated by externally applied heat, as by a small oil flame, and the steam formed, mixed with the oil, is ignited at the nozzle, the flame being directed on to the vaporiser. When the latter is sufficiently hot, live steam is passed through it instead of water.—R. S.

*Combustible Compound or Fuel, An Improved.* D. D. Esson, Kennington Park, London. Eng. Pat. 20,895, Sept. 21, 1896.

THE combustible compound is intended for burning in a closed chamber without the addition of air, and, if desired, in contact with water. It is proposed to form it of the following materials:—Nitroglycerin, 55 parts by weight; dry gun-cotton, 30 parts; vaselin, 10 parts; and camphor, 5 parts. An apparatus for using this fuel in the form of sticks is described in Eng. Pat. 20,894 of 1896.—R. S.

*Heating by Means of Liquid Hydrocarbons, Apparatus for.* S. Pitt, Sutton, Surrey. From Compagnie Internationale des Procédés Adolphe Seigle, Paris. Eng. Pat. 14,844, June 18, 1897.

THE apparatus consists of:—(1st) a closed reservoir containing water and air under pressure; (2nd) a bellical tube for vaporising water; (3rd) a reservoir for liquid hydrocarbons; (4th) a sprayer; and (5th), suitable connecting pipes, cocks, a gauge, and a compressed air and steam receiver. Air under pressure is led from the closed reservoir to the receiver and thence to the sprayer, to which also the liquid

hydrocarbons are led. These are then ignited, and the flame passing through the helical tube, raises its temperature. Water is now allowed to pass from the closed reservoir to the helical tube, and the steam therefrom to the receiver and sprayer, the air supply being cut off. An extremely hot flame is said to be produced.—R. S.

*Acetylene Gas, Impts. in Apparatus for the Generation and Storage of.* A. F. Bowers, Paris. Eng. Pat. 13,511, June 18, 1896.

THE improvements claimed comprise means for regulating the supply of water to the generator by the pressure of the gas in the latter. The pressure causes depression of the level of the feed water in one limb of a U-tube below the outlet to the generator, or moves a piston which cuts off the supply. Several forms of generating apparatus embodying such regulating devices are described. They are designed to obviate the necessity of a gasholder.—J. A. B.

*Acetylene Gas Generator, An Improved.* M. Duffield, Slough, Bucks. Eng. Pat. 17,646, Aug. 10, 1896.

LATERALLY perforated cells, packed with carbide, are admitted to a vertical cylinder through its base, which is then closed by a lid. Several of these generators are ranged round a bell gasholder, and water is admitted by a siphon device to each cell in turn until all are exhausted.—J. A. B.

*Acetylene Gas for Lighting Purposes, Impts. in and relating to Apparatus for Generating.* H. H. Lake, London. From O. Grenier and J. Grand, both of Lyons, France. Eng. Pat. 17,904, Aug. 12, 1896.

THE invention comprises a hopper with conical valve closing on knife edges and containing calcium carbide in grains 1 to 2 mm. in diameter, which are fed into a large tank of water at the base of the apparatus. The hopper and mechanism can be withdrawn from the receiver in which they are placed merely by disjoining water seals. Spy-glasses in the receiver and purifying apparatus are described.—J. A. B.

*Acetylene, Impts. in or relating to the Generation and Storage of.* G. W. Gaskell and R. R. Gibbs, both of Liverpool. Eng. Pat. 20,074, Sept. 10, 1896.

THE bell of a gasholder has a central tube reaching, when the bell is grounded, nearly to the bottom of the tank. A cylinder with perforated bottom contains carbide, and is supported in the tube by a tightly fitting plug. The gas escapes from this generating cylinder by a non-return valve to the gasholder, the rising of which lifts the carbide from the water.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Generating and Storing.* W. P. Thompson, London. From V. I. Comucci, San Giovanni di Val D'Arno, Italy. Eng. Pat. 20,694, Sept. 18, 1896.

A GENERATOR consisting of a container, bucket, and carbide basket, communicates by two tubes controlled by a single cock with the lower of two containers of a gasholder, the upper container of which has a float connected to an electric bell, and contains water which reaches the generator through one tube, while gas returns to the lower container through the other tube. A method of hermetically closing the generator is also claimed.—J. A. B.

*Acetylene Gas, Impts. in and relating to Apparatus for the Generation and Storage of.* A. Kay, Doune, Perth. Eng. Pat. 21,351, Sept. 26, 1896.

ONE or more generating vessels are placed at an inclination near a bell gasholder, and the supply of water to them from the tank of the latter is controlled by the movements of the bell.—J. A. B.

*Acetylene Gas, Impts. in and relating to Generators for.* A. H. Barker, London. Eng. Pat. 21,698, Sept. 30, 1896.

IN a generator with overhead water tank, the carbide container fits into a receiver attached to the roof of the generator. The receiver has cocks to prevent communica-

tion between the generator and the air during refilling of the container. The gas generated, passes to an overhead bell gasholder, the inlet to which is closed by the rising of the bell; any increase in pressure in the generator then drives the water away from the carbide.—J. A. B.

*Acetylene, Impts. in Apparatus for Generating and Storing.* E. Chesnay, Dijon, L. Pillion, Dijon, and C. Bertolus, St. Etienne, France. Eng. Pat. 21,758, Oct. 1, 1896. (Under Internat. Convention.)

THE water in a generator is in communication with an annular ring which forms the counterweight of a gasholder bell and surrounds the tank. Water flows from the generator to the ring when the bell rises, and the generation of gas is thus automatically controlled. A safety pipe, the orifice of which becomes unsealed before the bell rises unduly, is also claimed.—J. A. B.

*Acetylene Gas, Improved Process and Apparatus for the Production and Treatment of.* H. E. Oving, Rotterdam. Eng. Pat. 23,669, Oct. 24, 1896.

TO facilitate proper combustion of acetylene in any suitable burner, the patentee forms a mixture of the gas and air by letting the gas under the pressure at which it is generated, play upon the blades of a drum, which it rotates. Another drum on the same shaft is also thus rotated, and draws in air, which mixes with the gas in the space above the drums.—J. A. B.

*Acetylene or other Gas for Lighting, Heating, or other Purposes; Impts. in or relating to the Treatment of.* H. E. Oving, Rotterdam. Eng. Pat. 23,670, Oct. 24, 1896.

THIS invention consists in so proportioning the dimensions of the drums referred to in the preceding specification (23,669) that the mixture of acetylene and air is made in the desired proportions.—J. A. B.

*Acetylene Gas Generators, Impts. in.* H. K. Spence, A. Beveridge, W. G. Beveridge, and S. M. Beveridge, all of Kirkcaldy. Eng. Pat. 29,554, Dec. 23, 1896.

WITHIN a tank with removable lid is a gasholder bell suitably guided, and engaging, as it falls and rises, with catches, which operate valves regulating the admission of water to carbide containers below the tank. By a special device, when one container is exhausted, the water supply is automatically diverted to the other.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Producing.* F. Trendel, Berlin. Eng. Pat. 14,015, June 8, 1897.

SEVERAL carbide receptacles are so arranged in a generator that their contents are successively precipitated into the water by its rise. A telescoping safety device for acetylene gasholders is also claimed.—J. A. B.

*Petroleum Incandescence Burner without Wick.* G. Shenton, London, and D. A. F. de Villepigne, Paris. Eng. Pat. 16,351, July 23, 1896.

THE body of the lamp is shaped like a vase, the upper part, *a*, of which constitutes a closed receiver, from the bottom a tube, *b*, descending to the bottom of a second closed receiver, *c*, in the base of the lamp. From the top of *c* rises a tube, *d*, which ends within and near the top of a third closed receiver, *e*, supported a short distance below *a*. Finally, through the top of the receiver *e* passes an upright tube, *g*, the lower end of which is near the bottom of *e*, and the upper end of which terminates in the burner. The whole operates on the principle of the "fountain of Hero," oil poured into *a* rising in the tube *g* until it is rather more than 12 cm. above the oil level in *a*. From the top of the lamp body rises the burner, consisting of a metal block bored with a vertical passage communicating with *g*, and controlled by a screw cock; from the upper end of the passage rise tubular rods, which end in an annular chamber made between the adjacent faces of two cones, and at the upper (apex) part of the cones are an ejector, burner tube with air inlets, &c., surmounted by a mantle, as usual. Below the cones is fastened, between the hollow rods, a small cup,

nitrate, 10 parts; ammonium nitrate, 29 parts; strontium nitrate, 5 parts; rubidium nitrate, 1 part.—II. B.

*Incandescent Lamps for the Combustion of Petroleum.* Impts. in. W. Clark, Chancery Lane. From A. Meyenberg, M. Wendorf, and S. Henlein, Frankfurt-on-the-Main. Eng. Pat. 18,819, Aug. 25, 1896.

THIS invention relates to improvements on Eng. Pat. 23,863 of 1895 (this Journal, 1897, 36). It comprises the combination, with the expansible air-reservoir bulb contained in the upper part of the lamp base, of an air-pumping bulb situated in the lower part of the base, and connected with the reservoir bulb; a lever for operating the air-pumping bulb; and a lever for arresting the action of the air-pumping lever, the former being pressed upon and caused to act by the expanding air-reservoir when sufficiently inflated. There is described and claimed a cock for the petroleum and benzoline, rendered tight against leakage by making the cock plug and the cock casing of oppositely conical form at their larger end, so as to produce a groove of V form in cross-section, into which there is forced, by means of a screw-cap or other device, a presser ring, also of V section, an intermediate leather washer having been first placed between the two. The improved benzoline and petroleum reservoirs are also claimed.—II. B.

*Incandescence Lamp for Liquid Fuel.* O. Helfft, Berlin. Eng. Pat. 8807, April 6, 1897.

ROUND the upper part of the lamp is arranged a ring-shaped reservoir for the liquid fuel. At a lower part of the lamp, and connected with this reservoir, is a smaller ring-shaped reservoir, from which rise a number of thin tubes which pass upwards within a draught tube placed above the lamp chimney, and which serve as vaporisers for the fuel. The tubes meet at the top of the lamp in a small dome, from which two tubes pass downwards into a large glass globe, meeting in a small chamber partly filled with asbestos wool, from which rise an ordinary incandescence Bunsen burner, mantle, and chimney. All parts are arranged centrally, so that the heat from the Bunsen flame heats the vaporising

serving to hold spirit for the preliminary heating of the burner. After heating the burner, the screw cock is opened, allowing the petroleum to rise to the annular chamber, where vaporisation occurs. The lamp as a whole, and the various combinations, are claimed.—II. B.

*Incandescence Bodies for Illuminating Purposes.* Impts. in the Manufacture of. W. H. Wheatley, Chancery Lane. From C. Schmid, Brussels. Eng. Pat. 17,605, Aug. 8, 1896.

MANTLES are to be made as usual by impregnation in a solution of zirconium nitrate, 40 parts; calcium chloride, 15 parts; aluminium

tubes, dome, &c., maintaining a supply of gas. The igniting arrangement consists of a cup fitted beneath the vaporising tubes, and connected by a supply pipe to the reservoir, and on opening a cock with a bored plug, the cup receives a measured quantity of fuel; this filling cock also forms the ordinary cock for controlling the feed pipe of the vaporising tubes. To start the lamp, the fuel in the cup is lit, when the vaporisation of the fuel commences. All the combinations of parts, and the lamp as a whole (which is adapted for suspension), are claimed.—II. B.

*Rare Earths* ["Kosmia"]. A Process for the Separation of certain, and the Manufacture therefrom of Fabrics for use in Incandescent Gas Lighting. B. Kosman, Berlin. Eng. Pat. 18,915, Aug. 26, 1896.

THE patentee claims the discovery of a new earth, which he calls "oxide of ko-mium," in the cerium and didymium salts obtained from the crude liquor resulting from the solution of monazite sand. "The process of obtaining the new earthy oxide ('kosmia') from monazite sand and other cerite minerals, consists in first fractionally precipitating the hydrates of cerium, didymium, and lanthanum by adding peroxide of hydrogen and ammonia so that the solution retains an acid reaction, then treating the filtered-off solution with the same reagents, but adding so much ammonia that the solution becomes alkaline, separating the precipitate thus obtained from the liquor, dissolving the precipitate in nitric acid, treating this solution in the hot state with oxalic acid, washing the precipitate with hot acidulated water, decomposing the washed oxalate by heat, dissolving the residue in nitric acid, treating this solution with hydrogen peroxide and ammonia, so that the solution retains an acid reaction, separating the precipitate from the liquor, and adding ammonia in excess, whereby the hydrate of the new earthy oxide is obtained as a whitish precipitate." The use of the earthy oxide in incandescent lighting is also claimed.—II. B.

*Mantles and the like for Incandescent Gas Burners.* Impts. in and relating to. J. C. J. Steinbach, Hamburg. Eng. Pat. 14,499, June 15, 1897.

MANTLES composed of 99 parts of thorium and 1 part of ceria are said to give the maximum illuminating power obtainable from these two oxides, and if the ceria be increased to, say, 4 per cent., the light is yellowish and of much less illuminating power. According to the patentee, on adding 25 per cent. of silicic acid to a mixture of 96 parts of thorium and 4 parts of ceria, "the colour of the light emitted from a mantle made of said mixture is no longer a pronounced yellow, but is pure white, and its illuminating power is even greater than that of a mantle composed of 99 parts of thorium oxide and 1 part of cerium oxide." Nevertheless, "as a rule, with the presence of silicic acid, the percentage of cerium oxide in proportion to the thorium oxide, in order to obtain the most favourable illuminating effect, must not be appreciably greater than is the case with mantles or the like which are composed solely of thorium oxide and cerium oxide." The first claim is for "a mantle composed of thorium and cerium oxide characterised by a percentage of silicic acid."—II. B.

*Benzene or other Products contained in certain Gases.* Triple-Action Apparatus for the Recovery of. G. C. Marks, London. From "La Compagnie pour la Fabrication des Compteurs et Matériels d'Usines à Gaz," Paris, France. Eng. Pat. 10,577, April 28, 1897.

See under III., page 728.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Wood, Modern Distillation of, for the Production of Acetic Acid, Wood Spirit, and Acetone in a Pure Form.* M. Klar. Chem. Ind. 1897, 20, [9] and [10], 191—198 and 219—221 (see this Journal, 1897, 667—671).

WITH regard to the yields of products resulting from the destructive distillation of wood on a large scale, the results published by Sartig in a comparatively recent communication (this Journal, 1894, 389) may be taken as representing approximately reliable data.

A modern plant for the carbonisation of wood is illustrated; it is worked with eight horizontal retorts, capable of charring 8,000 Rm.\* of wood per annum (395.9 kilos. — 1 Rm.), no provision being, however, made for the utilisation of residual products.

**Preparation of Commercial Acetic Acid in a Pure Form.**—Grey calcium acetate contains as impurities, tarry constituents, and more especially homologues of acetic acid, the removal of which is accompanied with difficulty. For the purification on a large scale, one of the following two methods is adopted:—(1.) Conversion of crude acetic acid or calcium acetate into the sodium salt, purification of the latter by fractional crystallisation, filtration through charcoal, and decomposition of the higher fatty acids still present in the product, by fusion. (2.) In the second method calcium acetate is treated with strong mineral acids, and the resulting crude acetic acid subjected to fractional distillation in column stills. Since the higher homologous acids come over in the early stages of the distillation along with the more dilute products, the middle fractions are collected separately, and from them it is possible to obtain, by repeated rectification, an absolutely pure acid.

By decomposing the sodium salt, purified in the manner above described, with concentrated sulphuric acid, acids containing from 30 to 60 per cent. of acetic acid are obtained. For the production of higher strengths, the sodium salt must be dehydrated. It is essential to subject the distillate in every case to a second rectification, and this in the presence of some oxidising agent, and, for the preparation of glacial acetic acid, in the further presence of concentrated sulphuric acid, the apparatus used being illustrated by Figs. 14 and 15.

Although the products obtained from the pure sodium salt are characterised by excellence of quality, the commercial acids are mostly obtained direct from grey calcium acetate. The decomposition is effected by means of hydrochloric or sulphuric acids, the former being less generally employed, as it yields a weaker acid and acts more rapidly on the stills. Only the best qualities of acetate (80 to 82 per cent.) are treated, the lower grades necessitating a much larger consumption of oxidising agent, owing to the formation of sulphur dioxide, due to the presence of tarry matter.

Fig. 11 represents the apparatus in which the decomposition is effected. It consists of a flat cast-iron still provided with stirrers, which almost touch the bottom of the vessel. Sulphuric acid of 60° to 66° B. is gradually added,

Fig. 11.

the heating being effected by a direct fire, which should not be hot enough to give rise to the formation of acetone. Occasionally superheated steam is used, or the still is provided with a steam jacket and the distillation performed in a partial vacuum, a washing apparatus (containing alkali) being placed between the condenser and the exhauster to

absorb acid, which may be carried over mechanically. The resulting acid is then free from sulphurous anhydride, and sufficiently pure for commercial purposes without further rectification. A copper pipe, to which a mud or dust separator is attached, is fixed into the top of the still, and carries the vapours to a stoneware condenser immersed in a wooden tank. The construction of the condenser is shown in Fig. 12.

Fig. 12.

The crude acetic acid contains sulphurous anhydride, formic, propionic, and butyric acids, and empyreumatic oils. The latter come over at the commencement of the distillation, and are caught separately as an impure acid distillate. It has been proposed in France to use this liquid for denaturing acids (see Trade Rep., page 774) containing less than 10 per cent. of acetic acid (known as "acetic acid mauvais goût"). The crude acid is treated with "acetate" in small quantity, and subjected to distillation in a copper still provided with earthenware condenser, the contents being in the first place heated for two or three hours at a temperature slightly below the boiling point of acetic acid (120°). Thus the

impurities are removed to a great extent, although the distilled product is not sufficiently pure to pass the permanganate test. It is transferred to a still provided with a column apparatus, and oxidised therein at a temperature of 50° by the addition of chromic acid mixture or potassium permanganate.

In working up brown calcium acetate, the decomposition takes place in earthenware vessels, in which earthenware screens are suspended. Hydrochloric acid of 20° B. is used, the acetate being added gradually. The tarry and pitchy constituents remain on the screens, whilst the solution is introduced into a cast-iron still, which is heated by a direct fire. The still is surmounted by a tower containing a series of screens, the intervening spaces being filled with lumps of manganese dioxide. The acid vapours rising in the tower carry traces of hydrochloric acid into the partitions, whereby chlorine is liberated, the result being the production of a perfectly colourless acid. The final traces of acetic acid are expelled by the introduction of steam into the still. The acid is then oxidised and fractionated in a column still similar in construction to that used for the rectification of wood spirit. The columns are constructed of copper lined with porcelain, or entirely of stoneware. The

\* Rm. = Raum-metre, and refers to 1 cb. metre of wood in "Scheitern," i.e., rough pieces, each 1 m. long, piled as many as possible into a frame measuring 1 m. x 1 m. Roughly, 1 Rm. contains 0.75 cb. m. of solid wood.

stills are iron or copper, lined with stone slabs or enamelled, and are heated with steam coils or jackets. The vapours issuing from the column pass into the condensing worm, thence into the separator, to which a siphon pipe communicating with the column is attached, and are finally condensed in the cooler, the distillate being collected in earboys. The apparatus illustrated in Fig. 13 consists of an iron still,

Fig. 13.

lined with earthenware plates and joined together with a cement capable of resisting the action of acetic acid. The column is made up of a number of screen-like, perforated earthenware compartments with overflow cylindrical tubes. In some cases the partitions are filled with earthenware "cones," which have been recently introduced for rectifying and condensing purposes. They are easily cleaned, and are said to carry out the principle of dephlegmation more completely than any other appliance. To protect the workers

Fig. 14.

from the possibility of the sudden bursting of the column, it is surrounded by a copper-wire netting or provided with a metal screen placed loosely over the column, the intervening space being packed tightly with a clay material, which, upon the appearance of a rent, fixes itself firmly to the wall of the column and prevents the escape of gases or liquids. The condenser is a stoneware coil contained in a wooden tank.

On subjecting the crude acid from grey calcium acetate to rectification, the first fraction, which is a comparatively small one, consists of weak acetic acid, contaminated with other acids. It is introduced into commerce in strengths varying from 30 to 60 per cent. The next fractions, forming the main portion of the distillate, are perfectly pure, and are made up into acids containing from 80 to 100 per cent. of acetic acid. If necessary, the rectification is repeated, the strongest fractions being collected separately and utilised for the preparation of glacial acetic acid. The crude acid from brown calcium acetate yields on rectification a large proportion of weak acid, containing from 30 to 50 per cent., and only a comparatively small amount of concentrated acid. Although the strong acid (once or twice distilled) is quite pure and passes the requirements of the permanganate test, it lacks in so-called "bon goût," and is not suitable for culinary or medicinal purposes. To give it this quality, the respective fractions (80, 95, 96, to 100 per cent.) are distilled in a special apparatus, the construction of which is illustrated in Figs. 14 and 15. It consists of a copper still heated by a fire or a steam jacket. The still head, the pipe leading to the condenser, and the worm are composed of silver or of earthenware, glass, or porcelain, unacted upon by acetic acid. Although silver is the most durable material, earthenware protected with copper gauze is now largely employed. The distillation is sometimes carried on in the presence of concentrated sulphuric acid. Acids sold as 100 per cent. rarely contain more than 99 per cent., owing to the difficulty of preparing chemically pure acid in large quantities. A very pure acid may also be obtained by cooling the acid until it crystallises, removing the liquid portions, melting the crystals, and repeating this operation.

According to Sandmann (this Journal, 1883, 246), glacial acetic acid is obtained from the crude acid in one operation by subjecting it to distillation and allowing the vapour to pass into a second still, where it is separated into strong acetic acid, which is condensed, and weaker acid, which distils over.

Rohrmann proposes to concentrate and purify crude acetic acid by utilising the plate-towers designed by Lange and Rohrmann (this Journal, 1887, 584). The vapours rising within the column (maintained at a temperature of 120°) come into intimate contact with a constantly descending stream of concentrated sulphuric acid, to which eventually chromic acid is added, whereby, after one passage, the strength of the acid is said to be raised from 40 to 70 per cent. Heizerling obtains acetic acid from acetates by heating with magnesium chloride.

Johnson-Johnson (Stratford) proposes to purify the crude acid by repeated oxidation and rectification over acetate, glacial acetic acid being obtained by distilling with concentrated sulphuric acid.

Marco Michela prepares acetic acid from calcium acetate by distilling it with sodium bisulphate in a partial vacuum.

J. E. Johnson recommends the decomposition of calcium acetate with sulphur dioxide, separating the acid from the calcium bisulphite, recovering the sulphur dioxide from the latter, and purifying the crude acid in the usual manner.

The working of an acetic acid plant capable of treating 2,000 kilos. of calcium acetate in 24 hours is illustrated in plan and elevation, but without dimensions.

**Rectification of Crude Wood Spirit, 80° Tr.**  
—The raw material forming the source of rectified spirit, methylated spirit, and pure methyl alcohol, is largely imported into Germany, mainly from America and Austro-Hungary. It is a yellowish to brownish liquid,

Fig. 15.

has an empyreumatic odour, gives a turbidity with water differing in intensity with its purity, and contains as much as 12 per cent. of acetone. The following table gives the properties of a number of samples of wood spirit found in commerce. The acetone was determined according to Messinger's method (this Journal, 1896, 299), and the capacity for absorbing bromine according to the method prescribed by the German Excise for testing denaturing spirit:—

Name.	Colour.	Miscibility with Water.	Tralles Degrees.	Acetone Per Cent.	C.c. of Spirit required to Decolorise 100 c.c. of Potassium Bromide and Bromate Solution.
1. Crude wood spirit from Silesia .....	Yellow.	Very turbid.	80	6.44	50.00
2. Crude wood spirit (3) .....	Yellow.	Turbid.	80	10.00	15.00
3. Rectified wood spirit (3) .....	White.	Clear.	94	5.60	79.30
4. Rectified wood spirit from the Hartz....	White.	Clear.	92-95	37.46	14.75
5. Crude wood spirit from the Hartz.....	Yellow.	Clear.	85	20.94	51.20
6. Crude wood spirit (American) .....	Yellowish-brown.	Clear.	80	11.00	65.00
7. Rectified wood spirit ("A. xylylyse") ...	Almost white.	Clear.	98-99	4.80	52.00
8. Rectified wood spirit ("B. xylylyse") ...	Yellowish.	Clear.	95	13.72	19.40
9. Rectified wood spirit (Westphalian) ....	White.	Clear.	93-94	4.50	70.00

The first operation consists in converting the crude spirit into white rectified spirit by subjecting it to fractional distillation in a column still (see diagrams Nos. 8 to 10, this Journal, 1897, 670) in the presence of milk of lime. The first runnings are highly charged with acetone; the middle fraction gives a clear solution with water, show 99 to 99.5° Tr., and contains only a comparatively small amount of acetone. The last fractions give a turbidity with water and high iodine numbers, due to the presence of ketones, which react with iodoform like acetone. The miscibility with water decreases with the reduction in the percentage of alcohol, until finally wood oils come over. The following fractions were obtained by the rectification of American and Silesian wood spirit, 80° Tr.:—

1. *American Wood Spirit*.—894 kilos, gave—

- 50 kilos. of first runnings of 96° Tr., containing 57.72 per cent. of acetone.
- 491 kilos. of rectified white wood spirit of 99°-99.5° Tr., miscible with water (1:2) to a clear solution.
- 53 kilos. of rectified white wood spirit of 97° Tr., forming a turbidity with water.
- 47.5 kilos. of rectified white wood spirit of 96° Tr., forming a turbidity with water.
- 35 kilos. of wood spirit of 64° Tr.
- 50 kilos. of water of 9° Tr.
- 48 kilos. of water of 2° Tr.

2. *Silesian Wood Spirit*.—489 kilos, gave—

- 49 kilos. of first runnings of 94° Tr., containing 23 per cent. of acetone.
- 226 kilos. of white rectified wood spirit of 93°-93.5° Tr. Clear solution with water.

25 kilos. of white rectified wood spirit of 99° Tr., forming a turbidity with water.

51.4 kilos. of white rectified wood spirit of 97° Tr., forming a turbidity with water.

29 kilos. of wood spirit of 69° Tr.

65.5 kilos. of water of 5° Tr.

64.5 kilos. of water of 3° Tr.

Wood oils.

For the preparation of wood spirit for denaturing purposes, the first and last runnings containing much acetone, are redistilled, mainly with a view of obtaining a colourless product. This is then tested for specific gravity, percentage of acetone, and bromine absorption. The quantities of acetone and empyreuma are mostly below the excise standard, and are adjusted by the addition of pure acetone and last runnings. The mixture is then brought to a strength of 91° Tr., when it will be found to give the boiling points required by the German Excise. The following are the official tests framed in June 1888 and July 1896 for wood spirit used for the denaturing of alcohol:—

1. *Colour*.—The colour must not be darker than that obtained by dissolving 2 c.c. of a decinormal solution of iodine in a litre of distilled water.

2. *Boiling Point*.—100 c.c. of wood spirit are distilled in a metal flask provided at the top with a small globe, which is connected with a Liebig condenser. An officially standardised thermometer is fitted in the globe, and the flask is then moderately heated, so that the distillation proceeds drop by drop. The distillate is collected in a graduated cylinder, and when the thermometer indicates 75°, the barometric pressure being normal, at least 90 c.c. must

have come over. A correction of 1° in temperature is made for every variation of 30 mm.

3. *Miscibility with Water*.—20 c.c. of spirit mixed with 40 c.c. of water must give a clear or only slightly opalescent solution.

4. *Separation with Sodium Hydroxide*.—If 20 c.c. of the spirit be shaken with 40 c.c. of sodium hydroxide solution (sp. gr. = 1.13), at least 5 c.c. of the spirit should be separated after standing for half an hour.

5. *Percentage of Acetone*.—1 c.c. of a mixture containing 10 c.c. of spirit and 90 c.c. of water is introduced into a glass-stoppered cylinder and well mixed with 10 c.c. of sodium hydroxide solution (80 grms. of NaHO per litre); 5 c.c. of double normal iodine solution (254 grms. of iodine per litre) are then added, the mixture being again well shaken. The separated iodoform is taken up with 10 c.c. of ether (sp. gr. 0.722); 5 c.c. of the ethereal solution are then transferred with a pipette to a tared watch glass, evaporated to dryness, and weighed, after standing over sulphuric acid for two hours. The increase of weight should not amount to less than 0.07 grm.

6. *Capacity for absorbing Bromine*.—100 c.c. of a solution of potassium bromate and bromide, prepared in the manner described below, are treated with 20 c.c. of dilute sulphuric acid (1:3 of water). To this mixture, which represents a solution containing 0.703 grm. of bromine, wood spirit is added from a burette divided into 0.1 c.c., drop by drop, shaking all the time, until the colour of the bromine has disappeared. The addition of the spirit is regulated, so that not more than 10 c.c. are added per minute. Not more than 30 c.c. and not less than 20 c.c. should be required. The tests should be made in full daylight and the temperature should not exceed 20°. To prepare the bromine solution, pure potassium bromate and bromide are dried for 2 hours at 110° and allowed to cool in a desiccator. 2.447 grms. of the bromate and 8.779 grms. of the bromide are then dissolved in 1 litre of water.

The middle fractions obtained by the rectification of the crude naphtha are made up to certain strengths and brought into commerce as white rectified naphtha of the following qualities:—

- 90 per cent. (French spirit).
- 92—93 per cent. (English spirit).
- 95—96 per cent.
- 98—99.5 per cent. (pure spirit).

Although this product is "water-white" when first prepared, it gradually assumes a yellow colour, and gives a brownish to blackish coloration with concentrated sulphuric acid, due to the presence of empyreuma. It is purified by treatment with weak oxidising agents or by filtration through charcoal. In order to remove traces of ammonia and amines, the filtrate is treated with a small quantity of sulphuric acid and subjected to fractional distillation in a column still. In this manner a very pure product is obtained. The first and last runnings are collected separately and worked up into spirit for denaturing purposes.

For the valuation of the methyl alcohol prepared as above, it is converted into methyl iodide; this is distilled off and estimated by volume. (See Krell, *Berichte*, 6, 1310. Krämer and Grotzky, *Berichte*, 7, 1422, and 9, 1928. Bardsy and Borden, *Dingler's Polyt. J.* 233, 245.)

*Preparation of Acetone*.—This product, which is largely used in the manufacture of smokeless powder and the preparation of celluloid goods, is obtained by the destructive distillation of calcium acetate (80—82 per cent.). The operation is effected in the apparatus illustrated in Fig. 11. The construction of the mixer is of importance, as unless it is capable of thoroughly stirring the mass during the whole operation, the yield of acetone is greatly diminished. The best results are obtained by maintaining a dull red heat (500°—600°), care being taken that the pipes, which convey the gaseous products to the tar separator and condenser, are of sufficient width to prevent stoppages. They should, moreover, be constructed so that they can be easily and rapidly removed and replaced. Having heated the still to the requisite temperature, the mixer is started and finely ground calcium acetate (as dry as possible) introduced through the manhole. The distillation is then

proceeded with, which with a charge of 100 kilos. should occupy from two to three hours. The first distillate is water, originating from the moisture in the acetate. It is more or less coloured, has an empyreumatic odour, and contains a few per cent. of acetone. After a time the flow of water slackens, followed by a stage when hardly anything comes over; and when the temperature has risen high enough, acetone oils distil over. The total distillate forms a dark brown, highly inflammable liquid, having an empyreumatic odour and being contaminated with tarry substances and calcium acetate which has been carried over mechanically. On standing, it separates into two layers. The top layer, comprising about one-tenth of the bulk, contains the so-called "heavy acetone oils," whilst the bottom layer is chiefly composed of acetone and the lighter acetone oils held in solution by water. The following table gives the quantities obtained from 100 kilos. of grey calcium acetate, the consumption of fuel being 30 to 35 kilos. of coal:—

	Kilos.	Sp. Gr.	Acetone.	Acetone.
			Per Cent.	Kilos.
Acetone water .....	7—15	1.01	3.0	0.4
Crude acetone .....	32	0.90	67.5	22.0
Total distillate .....	42	0.93	53.5	22.5

The crude acetone thus obtained is largely contaminated with acetone oils, which are mainly composed of higher ketones originating from homologues of acetic acid present in calcium acetate; they also contain aldehydes, due to the presence of formic acid, condensation products of acetone, acids, phenols, and tarry substances. To minimise the formation of these secondary products and obtain better yields, Bauschlicher proposes to effect the decomposition in the presence of lime. Although the latter retains the tarry constituents, it does not act on the higher ketones and condensation products; and as these comprise by far the largest proportion of the secondary products, the author questions the utility of the process.

For the preparation of pure acetone, the crude product is diluted with water, treated with milk of lime, and allowed to stand for some time. The supernatant oily layer is then mixed with water and subjected to distillation in a column still. With a well-constructed apparatus the first rectification gives, as main fraction, a very pure product showing 99° to 99.5° Tr. and failing to give a turbidity with water. It contains only traces of aldehyde and empyreuma, and these are entirely removed by another distillation. The following are the commercial tests for English acetone:—(1.) The specific gravity should not exceed 0.802 at 15°, and the acetone should volatilise completely, without leaving a residue, when heated to 100°. (2.) When subjected to distillation, four-fifths of the original quantity taken should distil over at 58.8°, and, besides acetone, the residue should contain no substances other than those originating from the manufacture of acetone. (3.) 100 c.c. of acetone mixed with 1 c.c. of potassium permanganate solution (0.1 per cent.) should show no change of colour within two minutes. (4.) The acetone should not contain more than 0.005 per cent. of acid calculated as acetic acid. For testing this, 50 c.c. of acetone are diluted with 50 c.c. of water, 2 c.c. of a solution of phenolphthalein (1:1,000 alcohol of 50 per cent.) are then added, after which the mixture is titrated with sodium hydroxide solution (1 c.c. = 0.0006 grm. of CH<sub>3</sub>COOH).

The first and last runnings and the oils recovered during the clarification process with milk of lime are mixed together and redistilled, when a further quantity of suitable acetone is obtained. The residual oils constitute the so-called acetone oils, introduced into commerce as light oils (boiling between 75° and 130°) and heavy oils (boiling between 130° and 250°).

The boiling point of the commercial acetone oils is one lying between wide limits, and may be generally stated as from 75° to 220° C. The following results of a laboratory fractionation of 600 grms. of an acetone oil demonstrate

this, and also the proportions distilling at the various intervals of temperature.

91.5 grms at 72	85	light yellow.
97.5	85-95	"
116.5	95-115	yellow
81.0	115-130	"
66.5	130-145	"
34.0	145-160	"
23.0	160-175	dark yellow.
22.0	175-190	brown.
21.0	190-205	"
24.5	205-220	"
19.0	above 220	black residue.

*Natural Gas and Petroleum, Genesis of.* F. C. Phillips. Proc. Amer. Philos. Soc. 36, [154], 116-121.

CRITICISING the Mendeleeff hypothesis, the author points out that Moissan has shown that few of the metals form definite carbides, and that as these are metals of low specific gravity, their presence must—if they are regarded as producers of natural gas—be assumed at depths where heavy metals alone are believed to occur. Moreover, aluminium, oxidising, as it does, more readily than iron, would, in presence of this latter metal, precede it in order of oxidation, and be thereby rendered incapable of producing hydrocarbons. A boring driven to a depth of 2,900 feet in Ontario, and extending to within a short distance of the Archean rock, yielded gas from deep strata, underlying 1,600 feet of shale, which gas contained no hydrogen, acetylene, or carbon monoxide; and similar negative results have been given by Pennsylvania gas. Now, iron carbide according to Mendeleeff's theory, the active agent in the formation of gas, yields mainly free hydrogen; and although, if we regard the gas as a stored product, this constituent may, in the course of long ages, have escaped by diffusion, this could not occur so rapidly if the gas be a contemporaneous product, but a sufficient quantity to be estimated by chemical means would still be present in the gas issuing from the borehole.

Therefore, no theory of the origin of natural gas that assumes the production of free hydrogen, can be regarded as satisfactory until the presence of that constituent in the effluent gas can be demonstrated. The composition of the gas suggests that the formative reactions occurred at low temperatures, and that it has been stored below 500°C., since above that temperature, the constituents are more or less completely dissociated. Petroleum, on the other hand, contains hydrocarbons pointing to high-temperature reactions—a circumstance that should be considered in selecting any hypothesis as to its origin.—C. S.

*Petroleum (Pennsylvania), Suggestion as to the Origin of.* D. T. Day. Proc. Amer. Philos. Soc. 36, [154], 112-115.

THE theory advanced by MacGonigle ascribes the formation of the oil deposits in the Trenton and Clinton limestones to the action of the heat that, at the close of the carboniferous period, caused the uplift forming the Appalachian chain, which heat, passing through the Silurian limestones and shales, distilled the oil in the latter into the porous conglomerates of the Devonian age. The reasons advanced in support of this theory are, the absence of sulphur, the higher specific gravity, and the variations in colour in Pennsylvania oil, whereas the Silurian oil of Ohio exhibits converse peculiarities. Moreover, no oil has been tapped in Pennsylvania in the "corniferous" limestone, lying at the top of the Silurian period, though in Western Canada this formation is the chief oil rock; and it is also very doubtful (no remains having been discovered) whether any organic life existed in the Pennsylvania (Devonian) measures to form a source of petroleum. Another point adduced is that the profitable oil wells in this region all lie to the west of a line drawn from Brady's Bend to Waynesborough, whilst to the east of the line are found some of the richest gas pools, thus indicating that as the line of greatest upheaval (and therefore heat) is approached the distilled oil from the Silurian horizons remained in an uncondensed gaseous condition.

The author favours the above hypothesis, but considers the transference may have occurred without distillation, the existence of cracks in the cover over the Silurian limestones enabling the oil to leak through, and that filtration would account for the differences in colour the oil passing through first being the lightest in shade. As to how the removal of sulphur has been accomplished, this is more difficult to explain, though the action of aluminium chloride in this direction indicates a metallic chloride as the agency.—C. S.

*Petroleum, Nature and Origin of.* S. F. Peckham. Proc. Amer. Philos. Soc. 36, [154], 103-112.

IN discussing the Engler-Hofer theory of origin, the author expresses a belief that "steam has been a very potent factor in determining, not only the formation, but the transference of bitumens."

Texan turrellite he finds to consist of a white shell rock cemented by lime dissolved from the shells by hot water and then re-deposited, anterior to the introduction of the impregnating bitumen, and not composed of shells cemented together by bitumen, as generally asserted.

Esters of the pyridine bases have been discovered in the lighter fractions of Californian petroleum. Such petroleum on distillation decomposed even at 100°C. with evolution of  $H_2S$ , more or less separation of carbon, and rise of boiling point of the residue in the retort. Sulphur compounds have also been found by the author in Californian petroleum, and he considers that sulphur, as well as nitrogen, contributes to the conversion of petroleum, through "maltha," into asphaltum, the prime factors being polymerization, decomposition of the sulphur compounds with condensation of the residual molecule, and removal of hydrogen through deoxidation of the sulphates in the accompanying water, with substitution of sulphur in the oil. The fact that Californian petroleum is found to lose up to 25 per cent. by volume in four days at between about 70 and 90°, shows that at the surface, natural evaporation may also play a considerable part in this conversion.

In the large asphaltum deposit on the eastern side of the coast range (California), enormous springs of maltha have flooded the valleys in many places with large plains of asphaltum, the maltha being invariably accompanied by water, with many indications of the springs having at one time been hot and silicated, like those believed by the author to have produced the Trinidad pitch lake.

He thinks that no formula concerning the origin of petroleum and bitumen is capable of universal application but that in some places these bodies have been produced *in situ*, from animal remains; that in other instances the deposits contain primary distillates from older geological formations; and that in some cases bitumens "have been transferred and stored by a secondary invasion of bituminous deposits, by heat, steam, and pressure."—C. S.

*Petroleum and Natural Gas, Genesis and Chemical Relations of.* S. P. Sadtler. Proc. Amer. Philos. Soc. 36, [154], 93-102.

PASSING in review the different theories of origin put forward by various workers, the author refers to his own experience in the production of fluorescent "paraffine" oils, paraffin scale, and reduced petroleum oil or residuum, by redistilling the condensed vapours from linsed oil boiled under pressure, and he therefore considers that Engler's theory will have to be enlarged so as to include the vegetable seed oils as probable sources of petroleum.

—C. S.

*Petroleum (Pennsylvania, Ohio, and Canada), Constituents of, between 150° and 220°.* C. F. Mabery. Amer. Chem. J. 19, [6], 119-182.

PENNSYLVANIA oil consists, between these limits, of decane ( $163^{\circ}$ — $164^{\circ}$ ), decane—probably normal decane ( $173^{\circ}$ — $174^{\circ}$ ), hendecane ( $196^{\circ}$ — $197^{\circ}$ ), and dodecane ( $214^{\circ}$ — $216^{\circ}$ ), along with smaller quantities of aromatic hydrocarbons (mesitylene, &c.) of similar boiling points. Ohio (Trenton limestone) oil is represented by the same hydrocarbons of the  $C_{10}H_{20+2}$  series, the higher specific gravity being due to a larger percentage of the aromatic series.

Up to 173° the Canadian ("corniferous" limestone) oil is the same as the others, but the fractions 196—214° have the formula  $C_{20}H_{40}$ . Canadian oil contains a still larger proportion of aromatic hydrocarbons than the other two, and the higher fractions of all three probably contain other bodies, for the identification of which large quantities of distillate are required.

These results show a relation between the chemical composition of the hydrocarbons and the density of the crude oils, *viz.*, Pennsylvania, 0.80—0.82; Ohio, 0.82—0.85; Canadian, 0.85—0.88; whilst South American oil, sp. gr. 0.948, contains only the  $C_{20}H_{40}$  series, which also forms the chief portion of Caucasian oil, sp. gr. 0.88.

The precise action of sulphuric acid on petroleum distillates is still undefined, but the author considers that one of its chief functions consists in the removal of unsaturated hydrocarbons. Oxygen compounds appear to be mainly restricted to the higher fractions of American oil, though all the unpurified distillates examined, gave, in presence of sodium, flocculent precipitates of decomposition products, due to nitrogen or (more probably) oxygen compounds in small amount.—C. S.

#### PATENTS.

*Petroleum, Heavy Oils, Tar Oils, and Hydrocarbons generally; Improved Apparatus for Vaporising.* L. E. Fraipont, Paris. Eng. Pat. 19,861, Sept. 8, 1896.

In this apparatus the oil is fed into a retort, where it is distilled, the vapours then passing into a second similar retort, heated independently, wherein the lightest vapours are gasified, and thence to a gas producer—consisting of three tubes connected by ports—where the conversion into gas is completed. A portion of the gas may be utilised for heating the apparatus, and arrangements are made for discharging the residue from the retorts by the pressure of the internal gases, thus preventing the formation of coke. —C. S.

*Benzene or other Products contained in certain Gases, Triple-Action Apparatus for the Recovery of.* G. C. Marks, London. From "La Compagnie pour la Fabrication des Compteurs et Matériels d'Usines à Gaz," Paris, France. Eng. Pat. 10,577, April 28, 1897.

This invention relates to apparatus for the recovery of benzene from furnace gases or coke ovens, and it is also applicable for the extraction of any products contained in gas capable of solution in suitable liquids. It consists of an arrangement of chambers in communication with one another, containing revolving drums, the chambers being partly filled with a suitable absorbent or solvent liquid. The gas is caused to be dispersed throughout the absorbent so as to present a large surface for attack, whilst it pursues a tortuous course through each drum and chamber alternately. A triple action of the solvent liquid or the gas under treatment is secured by the passage of the gas through the revolving drum and buckets, the gas ascending in the shape of bubbles, producing, in the first place, the appearance of a boiling or convection of a very intense mechanical nature, which is augmented by a liquid "cascade or rain," produced by a revolving system of buckets. Thus, there is presented in the second place, a large surface to the upward current of gas. Thirdly, the oil flows like a cascade, through the action of a perforated sheet-iron spiral, and is thus enabled to act with increased advantage upon the upward current of the gas, so as to cause further absorption of benzene from it.—D. B.

#### IV.—COLOURING MATTERS AND DYES.

*α-Monochloroamphor, An Oxidising Action of.* H. Vittenet. Bull. Soc. Chim. 1897, 17, 705—712.

On heating aromatic amines (at 250° for four hours) with α-monochloroamphor, the author has observed the formation, in very small quantities, of certain colouring matters generally obtained by oxidation of the amines. For example, with *o*-toluidine, or a mixture of *m*-xylydine and aniline, magenta was formed, and with diphenylamine, there was produced Diphenylamine Blue.—A. C. W.

*The Saccharcins: New Colouring Matters derived from Saccharine.* P. Mounet and J. Kartsch. Bull. Soc. Chim. 1897, 17, 690—702.

Benzene sulphimide under certain conditions reacts with phenols and amidophenols to give compounds analogous to the phthaleins—

These substances, the saccharcins, have, in general, properties similar to those of the phthaleins. Thus, phenol saccharcin dissolves in alkalis to a red solution decolorised by acids; resorcinol saccharcin gives a yellow solution with a green fluorescence similar to that of fluorescein. Whilst fluorescein can take up two acid groups, resorcinol saccharcin combines with three molecules of acetic acid, to give a tri-acetylated compound.

The saccharcins of the substituted *m*-amidophenols are quite analogous to the rhodamines in colouring and general properties, but since the hydrogen in the group  $SO_2.NH$  may be replaced by acid or alcohol radicals, a large number of derivatives may be obtained. These saccharcins, however, differ from the rhodamines in that their coloured salts are instantly decolorised by alkalis, even by dilute ammonia in the cold. But if the saccharcin be transformed into the corresponding sulphurein, or if an acid radical be introduced in the imido group, the colouring matters obtained are among the most stable, towards alkalis.

*Resorcinol Saccharcin.*—Heat 18 grms. of saccharine for seven hours at 200—220° with 22 grms. of resorcinol and 2.2 grms. of aluminium chloride. When cold, powder, extract with dilute sodium carbonate solution, precipitate the colouring matter with acid, take up with alcohol, and precipitate by adding water. A brown resin is obtained with a green metallic reflection, soluble in alkalis to a yellow solution, insoluble in water but very soluble in alcohol. It could not be crystallised.

The acetyl derivative is formed by boiling with acetic anhydride under a reflux condenser, cooling, and pouring into alcohol. The crystalline precipitate is purified by solution in glacial acetic acid and precipitation by alcohol; it melts at 286°, and is insoluble in water. By boiling this acetyl derivative with alcoholic soda, diluting, filtering, and precipitating with water, the saccharcin is obtained in crystals, melting at 265°—267°.

*Tetra-ethyl-*m*-amidophenol Saccharcin.*—Heat 100 grms. of the amidophenol for 36 hours with 200 grms. of saccharine at 165°, powder the product, suspend in sodium carbonate solution, boil until carbon dioxide is no longer evolved, cool, and filter. The excess of saccharine may be obtained from the solution. The insoluble product is digested for several hours with caustic soda, filtered, washed, dissolved in dilute hydrochloric acid, and filtered. On cooling, the hydrochloride crystallises in small green crystals with a metallic lustre. These are very little soluble in water, but impart to it an intense reddish-violet colour with a yellow fluorescence.—A. C. W.

*α-Naphthol, Sulphonic Acids of.* P. Friedländer and R. Taussig. Ber. 30, 1456—1463.

The authors characterise and give methods of preparation of a number of the sulphonic acids of α-naphthol, and find that in several cases the zinc salt can be employed as a means of purification. The action of sulphuric acid on α-naphthol yields sulphonic acids in which the entering group has the position 2, 4, or 2', whilst 1.3'-naphthol sulphonic acid is only formed in small quantity. The same is also the case with 1.2-naphthol carboxylic acid, of which the 4.3' and 4.2'-sulphonic acids easily separate carboxylic acid, and naphthol carbonate also yields chiefly 4 and 4.2' derivatives, with but little 4.3'. For the preparation of other sulphonic acids, indirect methods have to be resorted to, such as the substitution of the amido group by hydroxyl, by decomposition of the diazo compound or the replace-

ment of a sulphonic acid group in a poly-sulphonic acid by fusion with caustic soda. Moreover, sulphonic acid groups in the  $\alpha$  position can be eliminated from  $\alpha$ -naphthol poly-sulphonic acids by treatment with sodium amalgam.

**1.2-Naphthol Sulphonic Acid.**—Equal weights of sulphuric acid and of finely powdered  $\alpha$ -naphthol are heated for a short time to 60–70° C. until dissolved. The melt, after cooling, is dissolved in water and extracted with benzene; when about 16 per cent. of the naphthol is recovered. A concentrated solution of potassium chloride precipitates the potassium salt of the acid as a sandy powder easily soluble in hot water, the yield (76–80 grms. from 100 grms. of  $\alpha$ -naphthol) being about 50 per cent. of the theoretical amount. This appears to be the only sulphonic acid of  $\alpha$ -naphthol which is sparingly soluble in dilute mineral acids.

**1.3-Naphthol Sulphonic Acid** can be prepared by diazotising and boiling 1.3-naphthylamine sulphonic acid (Ber. 28, 1951), or by eliminating the amido group from  $\gamma$ -amidonaphthol sulphonic acid (Ger. Pat. 57,910). It is purified by means of its zinc salt, which contains 8.5 H<sub>2</sub>O. As Gattermann has pointed out (Ber. 30, 54; this Journal, 1897, 232), the acid gives *o*-azo dyestuffs with diazo compounds.

**1.4-Naphthol Sulphonic Acid.**—The crude product was obtained by heating equal weights of sodium naphthionate and 50 per cent. caustic soda lye under pressure to 240–260° C. (Ger. Pat. 46,307), and purified by adding a small quantity of zinc chloride to a hot concentrated solution of the sodium salt, filtering, and precipitating with an excess of syrupy zinc chloride solution. The same acid can also be obtained by careful sulphonation of  $\alpha$ -naphthol with about an equal weight of sulphuric acid and 0.5 part of glacial acetic acid.

**1.4'-Naphthol Sulphonic Acid** is obtained by boiling diazotised 1.4'-naphthylamine sulphonic acid with dilute sulphuric acid (1:4), and is purified by means of the zinc salt. The acid yields 2.1.4'-nitrosonaphthol sulphonic acid with nitrite, and gives with iron salts the characteristic green reaction for *o*-nitrosonaphthols.

**1.2'-Naphthol Sulphonic Acid** is best prepared from 1.2.4.2'-hydroxy-carboxy-naphthalene disulphonic acid (Ber. 29, 37). When heated with acids to a high temperature, the carboxyl group 2 and the sulphonic acid group 4 are eliminated. This operation may also be performed in two stages. By prolonged boiling with 3 per cent. hydrochloric acid, the carboxyl group is removed, 1.4.2'-naphthol disulphonic acid being formed; whilst by heating for a short time to about 140° C. with tolerably dilute sulphuric acid, the sulphonic acid group 4 is split off, yielding 1.2.2'-hydroxy-carboxy-naphthalene sulphonic acid. A better method is to dissolve hydroxy-naphthoic-disulphonic acid in hot sulphuric acid boiling at 160° C., and heat for a short time to 140–145° C. The hydroxy-naphthoic-sulphonic acid then separates out, and is purified by dissolving in water and precipitating with concentrated hydrochloric acid. The acid (or its sodium salt) has the characteristic property of separating as a gelatinous mass from a hot aqueous solution. The conversion into 1.2'-naphthol sulphonic acid is best effected by heating under pressure with a little water to 120° C. This acid gives, with diazo compounds, azo dyestuffs unstable to acids. With *p*-nitrodiazobenzene in acetic acid solution, a yellowish-red dyestuff is obtained which turns violet-blue with alkalis, whilst in an alkaline solution, a diazo compound is produced which is brownish-red with acids and bluish-violet with alkalis. It is noteworthy that the fastness to alkalis of the sulphonated naphthol azo dyestuffs depends not only on the *o* position of the azo group, but also on the nature of the second component. Thus, almost all the azo derivatives of *p*-nitraniline (including those of the  $\beta$ -naphthol sulphonic acids and of 1.4'-naphthol sulphonic acid) are red when acid, and violet when alkaline.

**1.3.3'-Naphthol Disulphonic Acid**—This acid was obtained by Gürke and Rudolph (Ger. Pat. 38,281) by fusing 1.3.3'-naphthalene trisulphonic acid with caustic soda under pressure at 170°–180° C., but its constitution has not hitherto been determined. The same acid is formed by heating  $\alpha$ -naphthylamine disulphonic acid with three times

its weight of water to 180° C. Both acids give with diazo compounds, dyestuffs fast to acids, and on reduction give a solution which, when made alkaline, turns blue on exposure to the air (test for 2.1.4'-amidonaphthol sulphonic acids); and the complete identity of the acids formed by the two methods was proved by heating them with ammonia and sal ammoniac to 160–180° C., when 1.3.3'-naphthylene diamine sulphonic acid was obtained.

**1.2.4.2'-Naphthol Trisulphonic Acid**, which is employed technically for the manufacture of naphthol yellow S, possesses a characteristic sparingly soluble barium salt, which separates out on evaporating its aqueous solution, and is then no longer readily soluble. The salt is readily soluble in dilute acids and even in acetic acid. Sodium amalgam removes the sulphonic acid group 4, whilst sodium nitrite added to a solution of the barium salt faintly acid with hydrochloric acid gives an immediate precipitate of barium sulphate. The filtrate contains 4.1.2.2'-nitroso-naphthol disulphonic acid, which does not react with iron salts. According to Ger. Pat. 10,785, the trisulphonic acid is obtained by heating 1 kilo of  $\alpha$ -naphthol with 2 kilos. of 25 per cent. and 1.8 kilo. of 80 per cent. anhydride to 40–50° C.; but at a somewhat higher temperature, a not inconsiderable amount of the acid can be obtained by means of ordinary sulphuric acid. Thus, 1 kilo. of naphthol, after heating with 2.5 kilos. of sulphuric acid (66 B.) for 4 hours to 125° C. (some 80% is evolved) contains about one-seventh of the naphthol as trisulphonic acid, the remainder consisting chiefly of 2.2'- and 1.2'-disulphonic acids.—T. A. L.

*Observations on the Combination of Diazo Compounds with Phenols.* C. Gassmann and H. George. Comptes Rend. 1897, 125, 306.

GRIESS, Roussin, and others have shown that phenols in general and naphthols in particular combine with the alkaline salts of diazo compounds. This reaction is subject to certain conditions. Phenol itself will not combine with normal diazo compounds in presence of sodium acetate, while resorcinol and  $\alpha$ -naphthol sulphonic acid (OH:SO<sub>3</sub>H = 1:4) readily combine with diazo compounds, even in very acid solutions. From their experiments, the authors conclude that all the phenols and naphthols which, on combination with normal diazo compounds, form ortho-oxazo substances, react either in neutral or acid solution.  $\beta$ -naphthol combines differently according to the solvent. Thus, in the reaction with mono-diazotised phenosulfuric acid, if the  $\beta$ -naphthol is dissolved in acetic acid, a very soluble colour (Diazine Blue, Naphthindone) is formed—

while in alkaline solution a less soluble colour is obtained. 15 per cent. solutions of  $\beta$ -naphthol in triacetyl glycerin can also be used, and they possess the advantage of being very permanent.

Nitrated diazo compounds react with phenols much more readily than do the non-nitrated diazo substances. For example, if a mixture of the chlorides of diazobenzene and *p*-nitrodiazobenzene reacts with  $\beta$ -naphthol in either neutral, acid, or alkaline solution, *p*-nitrobenzene-azo- $\beta$ -naphthol is almost exclusively formed. This fact is interesting in connection with the manufacture of Anthracene Red (Ger. Pat. 72,867, Fr. Pat. 223,176), which probably has the constitution—

Ortho mono-nitro-benzidine is diazotised and combined, first with salicylic acid, and then with  $\alpha$ -naphthol sulphonic

acid ( $\text{OH} \cdot \text{SO}_3\text{H} = 1.4$ ); if the order of combination be reversed, a colour of no commercial importance is obtained. —C. M.

*Dye-stuffs. Synthetic Manufacture of. II.* L. Paul. *Zeits. f. angew. Chem.* 1896, 679—692.

1. *Dye-stuffs from Dehydrothio Bases.*—When *m*-xylylidine is heated with sulphur, two thio compounds are produced, having the following formulae:—

The former is employed for the manufacture of Erixa and Salmon Red, whilst the latter, when combined with  $\beta$ -naphthol sulphonic acid (Schaeffer), yields Emin Red. The two isomers can be separated by means of hydrochloric acid (20° B.), in which isothioxylylidine is perfectly insoluble. The dehydrothioxylylidine is employed as sulphate in the form of a 28—30 per cent. paste. 10 kilos. of the paste are mixed with 40 kilos. of hydrochloric acid (20° B.), allowed to stand overnight, cooled with 50 kilos. of ice, and diazotised with 10.9 kilos. of a 25 per cent. nitrite solution diluted with 11 litres of cold water. The whole is then diluted to 250 litres and filtered if necessary. For the preparation of Salmon red, the solution so obtained is run into 120 kilos. of a 19 per cent. Amido-R-salt solution,  $2,3,3',4',10\text{H}_5 \cdot \text{NH}_2(\text{SO}_3\text{H})_2$  (obtained by the action of ammonia on R-salt), containing 50 kilos. of sodium carbonate, with constant agitation. After stirring three hours, the dye-stuff is filtered, washed, pressed, and dried. The yield is 17 kilos., which is diluted for the market with 15 per cent. of sodium sulphate. The product dyes unmordanted cotton salmon shades. The experiments carried out by the author on the manufacture of Erixa (diazotised dehydrothioxylylidine and  $\alpha$ -naphthol- $\epsilon$ -disulphonic acid) did not give satisfactory yields, probably due to the presence of the large quantity of acid necessary for the diazotisation. He considers it probable that in order to increase the yield, it is necessary to precipitate the diazo compound by means of salt, sodium sulphate, nitrate, acetate, or the like. The dyestuff gives bluish red shades on unmordanted cotton.

*Emin Red.*—50 kilos. of dry isothioxylylidine chloride are stirred into 160 kilos. of sulphuric acid (66° B.) in a jacketed, lead-lined vessel. When completely dissolved, which requires a temperature of about 50° C., the whole is run into 700 litres of water and 200 kilos. of ice. The vat is then filled up with water, the sulphate allowed to settle, part of the clear liquor run off, leaving sufficient sulphuric acid for the diazotisation. At a temperature of about 5°—10° C., 20 kilos. of nitrite as a 10 per cent. solution are then run in until the diazotisation is complete. After filtering the diazo solution, it is run into 1,200 litres of water containing 52 kilos. of 100 per cent. Schaeffer salt and 70 kilos. of sodium carbonate. The dyestuff is finally salted out with 30—50 kilos. of salt, yielding, after drying, about 130 kilos. of dyestuff. Emin Red is very sparingly soluble in water, and dyes chromed wool red, absolutely fast to milling. The combinations with 1,4-naphthol sulphonic acid and with R-salt give bluer dyestuffs, but they are not so fast to milling.

Fig. 1.

*Dehydrothiotoluidine.*—6 kilos. of *p*-toluidine and 1.5 kilo. of sulphur are heated in a cast-iron pot provided with an agitator to 190—195° C. (Fig. 1). Water and *p*-toluidine collect in A, and B contains 6 kilos. of soda-lye (40° B.) in order to absorb the sulphuretted hydrogen. After heating for five hours to 190°—210° C., the receiver is changed and the *p*-toluidine distilled off in about 2½ hours by heating to 300° C. (Fig. 2). Altogether about 2.7 kilos. of *p*-toluidine

Fig. 2.

distil over, and the residue, weighing 3 kilos., is dissolved in a boiling mixture of 9.6 kilos. of sulphuric acid (66° B.) and 14.5 litres of water. The solution is run into 200 litres of water and the sulphate filtered off. The paste weighs 34.5 kilos., and, on titration with 10 per cent. nitrite, contained 2.8 kilos. of 100 per cent. thio-base sulphate, equal to 75.7 per cent. of the theoretical yield. According to Cassella and Co. (Ger. Pat. 53,938), an increased yield is obtained by using naphthalene as a diluent for the melt, the proportions being 2 kilos. of *p*-toluidine, 1.6 kilo. of sulphur, and 2 kilos. of naphthalene.

Fig. 3.

The melt is heated in a Papin's digester enamelled inside, for six hours to 190°—210° C. (Fig. 3), when it is poured into a hot mixture of sulphuric acid (66° B.), 8 kilos., and water, 12 litres. On boiling, the naphthalene separates, is allowed to cool, and filtered off through jute, the filtrate being precipitated by pouring into 150 litres of water, and titrated with nitrite as above. The yield obtained was 50 per cent. of the theoretical. 20 kilos. of a 5.4 per cent. thio-base paste (= 1.1 kilo. dry) are stirred up with 80 litres of water and diazotised with 1.29 kilos. of a 25 per cent. nitrite solution and 3.7 kilos. of hydrochloric acid (12° B.) (= 4 mols.). This is then run into 59 kilos. of a 3 per cent.  $\alpha$ -naphthol  $\delta$ -disulphonic acid containing 2.5 kilos. of sodium carbonate. After boiling up and salting out, 2.4 kilos. of a dyestuff are obtained which give yellower and stronger shades on unmordanted cotton than Geranin 2B. Similar but still yellower dyestuffs are obtained from  $\alpha$ -naphthol- $\epsilon$ -disulphonic acid or from 1,4-naphthol sulphonic acid, but none of these dyestuffs approach in brightness and blueness, those derived from thioxylylidine.

2. *Salicylic Acid Dye-stuffs.*—These products, like the alizarins, are lake-forming dyestuffs, and hence are applicable to chrome-mordanted wool, possessing to a high degree fastness to light and milling. Representatives of this class of dye-stuffs are Flavazol and Alizarin Yellow R. The former is obtained by combining *p*-toluidine with salicylic acid, giving a product which, after dilution with 5 per cent. of sodium sulphate, forms Flavazol Extra. Flavazol is obtained by diluting Flavazol Extra with 60 per cent. of sodium sulphate. Alizarin Yellow R is formed from diazotised *p*-nitraniline and salicylic acid, and gives on chromed wool somewhat redder shades than Flavazol.

3. *Tropaeoline, Metanil Yellow and Orange.*—Tropaeolin 60 from diazotised sulphanilic acid and diphenylamine is prepared as follows:—9 kilos. of aniline are stirred into 10 kilos. of sulphuric acid (66° B.) and heated in an oil-bath for 7—8 hours to 215° C. The product is dissolved in water with 5.5 kilos. of sodium carbonate, boiled to remove unaltered aniline, and, after filtering, precipitated with hydro-

chloric acid. It is then mixed with the calculated quantity of nitrite in 100 litres of water, and 10 kilos. of dilute sulphuric acid (66° B.) are run in within about half an hour, the temperature being kept at 10°–15° C. Meanwhile 18 kilos. of diphenylamine, 63 kilos. of dilute sulphuric acid and water are dissolved in a leaden vessel and allowed to run in a thin stream into the diazo solution obtained as above. The colour acid so formed is filtered, washed, and finally dissolved in dilute potash solution, when the whole is transferred to a boiler (Fig. 4), in which it is heated by

Fig. 4.

means of the wet steam pipe *c*, any excess of diphenylamine distilling off through *a*. When the distillate is free from diphenylamine, *a* is closed, and the solution is forced by means of *b* through a filter-press into a crystallising vat, where, on cooling, the dyestuff separates out. The sulphanilic acid can also be prepared by means of the laking process, for which purpose 24 kilos. of aniline are run in a thin stream into 27 kilos. of sulphuric acid (66° B.) contained in a cast-iron vessel furnished with an agitator (Fig. 5).

Fig. 5.

The yield of acid sulphate is 49.6–49.7 kilos. 32 kilos. of the salt are heated in an iron chamber, of which a section is given in the accompanying Fig. 6.

Fig. 6.

The temperature is maintained at 230–235° C. until sulphurous acid is no longer given off. The yield is about 29.5–29.6 kilos., which is close to the theoretical. Traces of aniline are removed as above by boiling the alkaline solution. Naphthionie acid can be prepared in a similar way. Melted naphthylamine is poured into the quantity of concentrated sulphuric acid (66° B.) necessary for the acid sulphate, the temperature rising to 180–200° C. In order to keep the mass porous, oxalic acid is added to the melt before baking it. In place of the method given above for the preparation of Tropæoline, it can also be made in an alcoholic solution. 10 kilos. of sulphanilic acid free from aniline are dissolved in 36–40 litres of boiling water with

soda lye and diazotised with 15 kilos. of hydrochloric acid and 4.2 kilos. of nitrite in a concentrated solution at about 7–8° C. The diazo compound, after filtering, is mixed with a small quantity of ice water, and run into 7 kilos. of diphenylamine dissolved in 200 kilos. of alcohol (84–90° Tr.) and 50 kilos. of hydrochloric acid. After standing some time the temperature is allowed to rise to 15° C., when the dyestuff is filter-pressed, and 15–18 kilos. of the product are boiled up with 100–150 litres of water, 4–5 kilos. of ammonia added, and the whole allowed to cool to 30° C., when crystals of the ammonium salt separate out. The yield is 12–14 kilos. of Tropæoline, which is made up to 16 kilos. with sodium sulphate. The spirit is recovered by liming and distillation, and the loss on a monthly consumption of 12–16,000 kilos. is 7–9 per cent., or in summer about 10–12 per cent.

**Metanil Yellow.**—Metanilic acid is prepared by heating together, at a temperature not exceeding 110° C., 55 kilos. of fuming sulphuric acid and 15 kilos. of nitrobenzene. When the latter has disappeared, the melt is blown into about 350 litres of water, and reduced by adding 27 kilos. of zinc dust. The reduced solution is then allowed to settle, filtered, cooled with ice, diazotised at 5°–10° C. with 5.7 kilos. of nitrite, and 10 kilos. of dilute sulphuric acid are finally added. The combination with 20 kilos. of diphenylamine is performed as above. In place of zinc dust, the following process may be employed:—75 kilos. of nitrobenzene are run into 150 kilos. of fuming sulphuric acid at 100°–105° C. The melt is then heated for two hours to 110–115° C., then blown into 1,000 litres of water, and reduced with 75 kilos. of cast-iron borings in the course of 1½ to 2 hours. After boiling up liming, and filtering, the calcium salt solution is concentrated to 22°–24° B and filtered from calcium sulphate. The yield is 300–320 kilos. of a 32–36 per cent. strength, corresponding to 100–110 kilos. of metanilic acid. The combination with diphenylamine can take place in an alcoholic solution, and 20–25 kilos. of the colour acid so obtained are boiled up with 200 litres of water and 4–5 kilos. of sodium carbonate, filtered, mixed with 25–30 kilos. of salt, and allowed to cool to 30° C., when 18–20 kilos. of Metanil Yellow (M G F) crystallise out, which, after grinding with salt, give about 55 kilos. of Metanil Yellow (M G F O O). The colour acid can also be converted into a sulphonic acid by treatment with five-sixths its weight of fuming sulphuric acid (40 per cent. SO<sub>3</sub>) at about 60° C. The solution of the calcium salt is then evaporated nearly to crystallisation, converted into the sodium salt, and dried down.

**Curcumin.**—About 19–21 kilos. of pure Tropæoline are stirred up with water and treated with 1–5 kilos. of nitrite as a 25 per cent. solution, 18 kilos. of nitric acid, and 21 kilos. of sulphuric acid (66° B.). The whole is then boiled for three hours, when quantities of nitrous acid vapours escape. After filtering, the dyestuff is salted out and pressed.

**Orange II.** is produced from diazotised sulphanilic acid and β-naphthol. The former is obtained as above described, but no details are given as to the strength of the naphthol solution or as to yield.

**Orange R.**—60 kilos. of α-naphthol are added to 96 kilos. of sulphuric acid heated to 70° C., and raised to 90° C. for three hours. The melt is dissolved in

water, and this solution is poured into 505 litres of brine containing 100–150 kilos. of salt. After filtering off the precipitated acid sodium salt of the  $\alpha$ -naphthol sulphonic acid, the filtrate is treated with 10 kilos. of sodium carbonate, and a solution of diazoxylene (from 12 kilos. of xylidine, 30 kilos. of hydrochloric acid, and 1,000 litres of water) is run in. This yields, after salting out with 300 kilos. of salt, about 80 kilos. of Orange R. The acid sodium salt of the  $\alpha$ -naphthol sulphonic acid is dissolved in 1,250 litres of water, boiled up with 70 kilos. of sodium carbonate, and filtered. The solution is halved and combined with diazoxylene as above. The filtrate still contains some naphthol sulphonic acid, which is combined with the diazonaphthalene sulphonic acid from 8 kilos. of naphthionate, 150 litres of water, 12 kilos. of hydrochloric acid, and 2.5 kilos. of nitrite. The yield of Ponceau is 15 kilos. In Ger. Pat. 28,820, the author describes a process for the production of brown and red dyestuffs, and in the present paper, details of the manufacture are given. The products obtained, however, have been replaced by others which show a greater evenness in dyeing and are faster to milling. The process consists in combining diazotised amido-azobenzene with naphthionic acid, and converting the dyestuff so obtained into the corresponding naphthol derivative by diazotising and boiling with water. The following method is given for the preparation of amido-azobenzene. A vat holding 1,000 litres, provided with a cover, agitator, and draught pipe, contains 464 kilos. of aniline. Whilst the agitator is running, about 640 kilos. of hydrochloric acid (20° B.) are run in, until Congo paper is turned blue or magenta paper white. The temperature rises to about 75° C. 27.6 kilos. of the mixture are mixed in a half petroleum cask with ice, bringing the temperature to about 8–10° C. 13.8 kilos. of nitrite solution are run in, keeping the temperature by means of ice at about 10° C. The diazo-amidobenzene formed is placed in a second vat and agitated, when the transformation into amido-azobenzene takes place. It is complete when a sample dissolved in alcohol and a few drops of ammonia does not turn red on the addition of soda lye. The amido-azobenzene hydrochloride is filtered off on flannel, and washed with water and hydrochloric acid about six times to obtain it free from aniline. The yield is 173 kilos. of a 44 per cent. paste = 76 kilos. of dry amido-azobenzene hydrochloride from 116 kilos. of aniline. Adding to this the amount of aniline recovered from the wash liquors, the yield is 75 per cent. of the theoretical. For the diazotisation, the above amido-azobenzene hydrochloride is stirred up with a small quantity of water, and brought up with 63 kilos. of hydrochloric acid and 150 kilos. of ice to about 400 litres. 25 kilos. of nitrite in 50–75 litres of water are then run in, so that nitrous acid and ice are always present. The volume increases to about 1,000 litres. The diazo compound is filtered off and washed four times. The filtrate, together with the first wash water is precipitated with Chili salpêtre or nitric acid, the total yield being 376 kilos. of diazo-azobenzene paste, which, on titration with Schaeffer salt, corresponded to 18 kilos. of aniline. On combination with sodium naphthionate, the author obtains Cotton Red, which, on diazotisation and boiling with water, yields Fast Red. Neither of these colours has, however, any technical importance. When amido-azobenzene is treated with fuming sulphuric acid, it is converted into a mono- and a disulphonic acid. The former, when diazotised and combined with 2.1-naphthol sulphonic acid, yields Croceine 3 B, whilst the disulphonic acid gives with  $\beta$ -naphthol, Hebrich Scarlet. For the sulphonation, the hydrochloride is heated with 2½ times its weight of alcohol and ammonia, filtered, and the filtrate precipitated with sulphuric acid. One kilo. of the dried, ground, and sieved sulphate is added to 1.5 kilo. of fuming sulphuric acid (25 per cent.  $\text{SO}_3$ ), the temperature being kept below 35° C. A further quantity of 2.5 kilos. of the fuming acid is then added, and the melt is maintained at 35° C. until a sample dissolves in dilute ammonia. The principal products then are mono- and disulphonic acid, whereas at 70° C., di- and trisulphonic acids are chiefly formed. In the former case the melt is poured into brine and the precipitate extracted with boiling water, when the monosulphonic acid remains behind as a brownish-yellow paste. The disulphonic acid is precipitated by salt from the

filtrate in bluish-red plates or needles. The diazo compound of the monosulphonic acid is almost insoluble in water, whilst that of the disulphonic acid is only precipitated on adding salt. By combining this latter with sodium naphthionate, a brown dyestuff for wool is obtained. When this is diazotised and boiled with water, it forms a red dye-stuff which dyes wool from an acid bath and cotton from an alum bath bluish-red, but lacks advantages rendering it of technical importance.—T. A. L.

*Dyestuffs [Synthetic], and Raw Products therefor; Manufacture of.* III. L. Paul. Zeits. angew. Chem. 1897, 20—25, and 47—52.

The diazotisation of diamidotriphenylmethane and its homologues, and subsequent conjugation with R salt, gives a series of red dyestuffs for wool, which cannot, however, compete with the various Ponceaus, both on account of price and from the fact that they do not exhaust the dye-bath. They are, however, employed for the production of lakes and for printing, one of these being Vermilion Scarlet. Diamidotriphenylmethane is obtained by heating together under a reflux condenser for 3–4 hours, 53 grms. of benzaldehyde, 93 grms. of aniline, and 130 grms. of hydrochloric acid (20° B.). About 41 c.c. distil over, containing 4.5 c.c. of benzaldehyde. The melt is dissolved in 750 c.c. of water, steamed to remove unaltered benzaldehyde, made alkaline, and again steamed to remove aniline, and the diamidotriphenylmethane is filtered off. To purify it further, it is again dissolved in hydrochloric acid and carefully neutralised with sodium carbonate solution. The yield is 250 grms. of paste = 88 grms. of 100 per cent. base, or 65 per cent. of the theoretical yield. For the diazotisation, 50 grms. of the paste are dissolved in 250 c.c. of water, together with 75 grms. of hydrochloric acid (12° B.). A 10 per cent. solution containing 8.8 grms. of sodium nitrite is then slowly added, and the clear diazo solution, measuring about 750 c.c., is run into 500–700 c.c. of water containing 65 grms. of R salt and 40 grms. of sodium carbonate, so that the final volume amounts to about 2 litres. After standing some time, the whole is warmed to 50°–60° C., and separated by means of 500–600 grms. of salt, when the dye-stuff is filter-pressed and dried. The yield of damp paste amounts to 130 grms. = 87.5 grms. of dry dyestuff containing 10.5 grms. of salt. From 200 grms. of base, 342 grms. of dyestuff were obtained free from salt. For producing a lake, four solutions were made up, containing (1) 71 grms. of sodium carbonate; (2) 216 grms. of barium chloride; (3) 130 grms. of magnesium chloride; (4) 43 grms. of caustic soda, each in 1 litre of water. 2 grms. of the colour were dissolved and mixed successively with 50 c.c. of (1), 50 c.c. of (2), 25 c.c. of (3), and 25 c.c. of (4). The lake is then filtered off, smeared on paper, and dried. Compared with Vermilion Scarlet, the colour is 10 per cent. stronger, but also bluer. On substituting G for R salt, only an incomplete combination takes place with the diazotised diamidotriphenylmethane. By condensing *m*-xylidine with benzaldehyde as above, diazotising the base, and combining it with R salt, an orange lake is obtained. From *p*-toluidine (107 grms.), 53.5 grms. of benzaldehyde, and 130 grms. of hydrochloric acid, a yield of only 17 grms. of the diamido base was obtained. When *p*-xylidine 1,210 grms., benzaldehyde 530 grms., and 1,300 grms. of hydrochloric acid are heated together under a condenser for 45–60 minutes at 110° C., a separation of the diamido hydrochloride takes place. After filtering off and washing with 1–1.5 litres of hydrochloric acid, a yield of 1.1 kilo. is obtained, corresponding to 50 per cent. of the theoretical. A further amount can be obtained by prolonged heating of the mother-liquor. A nitro derivative of this base is formed by heating together 7.2 grms. of *p*-nitrobenzaldehyde, 11 grms. of *p*-xylidine, and 11.5 grms. of hydrochloric acid. The melt, after dissolving in water and filtering, yields the base on adding sodium carbonate. By applying the condensation to dimethyl-*p*-xylidine, a tetramethylated base is obtained, which, on oxidation with lead peroxide, gives a green soluble in spirit. Dimethyl-*p*-xylidine is prepared by heating 20 grms. of *p*-xylidine, 70 grms. of methyl iodide, 47 grms. of sodium carbonate, and 500 c.c. of water under an inverted condenser until the methyl iodide has disappeared. After extracting with ether
